Getting Started

Introduction

Quantitative trading is a method of trading where computer programs execute a set of defined trading rules in an automated fashion. Quants take a scientific approach to trading, applying concepts from mathematics, time series analysis, statistics, computer science, and machine learning. Compared to discretionary traders, quants can respond faster to new information and are at less risk to their emotions during trades. Since quants can concurrently trade many strategies while discretionary traders only have the mental bandwidth to trade a small number of concurrent strategies, quant traders can have more diversified portfolios.

Learn Programming

We aim to make it as easy as possible to use QuantConnect, but you still need to be able to program. The following table provides some resources to get you started:

Language	Type	Name	Producer
C#	Video	C# Fundamentals for Absolute Beginners	Microsoft
C#	Text	C# Jump Start - Advanced Concepts	Microsoft
C#	Video	Top 20 C# Questions	Microsoft
C#	Text	C# Tutorial	tutorialspoint
Python	Text	Introduction to Financial Python	QuantConnect
Python	Text/Video	Introduction to Python	Google
Python	Interactive	Code Academy - Python	Code Academy
Python	Text	Python Pandas Tutorial	tutorialspoint

Enroll in Bootcamp

Bootcamp is an online coding experience where QuantConnect team and community members teach you to write your first algorithms. Bootcamp gives you step-by-step instructions on practical and beginner-friendly topics, so it's a great

way to learn LEAN. The lessons cover many topics that you use as you write your own algorithms, including universe selection , indicators , and consolidators . To get started, check out the course library .

Example Algorithm

The following video demonstrates how to implement an algorithm that buys and holds an S&P 500 index ETF:

```
# Import all the functionality you need to run algorithms
from AlgorithmImports import *

# Define a trading algorithm that is a subclass of QCAlgorithm
class MyAlgorithm(QCAlgorithm):
    # Define an Initialize method.
    # This method is the entry point of your algorithm where you define a series of settings.
    # LEAN only calls this method one time, at the start of your algorithm.
    def Initialize(self) -> None:
        # Set start and end dates
        self.SetStartDate(2018, 1, 1)
        self.SetEndDate(2022, 6, 1)
        # Set the starting cash balance to $100,000 USD
        self.SetCash(100000)
        # Add data for the S&P500 index ETF
        self.AddEquity("SPY")

    # Define an OnData method.
    # This method receives all the data you subscribe to in discrete time slices.
    # It's where you make trading decisions.
    def OnData(self, slice: Slice) -> None:
        # Allocate 100% of the portfolio to SPY
        if not self.Portfolio.Invested:
            self.SetHoldings("SPY", 1)
```

Key Concepts

Algorithm Engine

Introduction

LEAN Engine is an open-source algorithmic trading engine built for easy strategy research, backtesting, and live trading. We integrate with common data providers and brokerages, so you can quickly deploy algorithmic trading strategies. The core of the LEAN Engine is written in C#, but it operates seamlessly on Linux, Mac and Windows operating systems. To use it, you can write algorithms in Python 3.8 or C#. QuantConnect maintains the LEAN project and uses it to drive the web-based algorithmic trading platform on the website.

Since LEAN is open-source, you aren't locked-in to the QuantConnect platform. You can run LEAN with your own infrastructure, data, and brokerage connections. If you use QuantConnect, our team of engineers manage the infrastructure, you can run the latest version of LEAN with all of its brokerage connections, and you can utilize the datasets in the Dataset Market .

Your Algorithm and LEAN

To create a trading algorithm with LEAN, define a subclass of the `QCAlgorithm` class. LEAN loads your algorithm into the engine during the building and compilation process. LEAN runs an algorithm manager that synchronizes the data your algorithm requests, injects the data into your algorithm so you can place trades, processes your orders, and then updates your algorithm state.

The LEAN engine manages your portfolio and data feeds, so you focus on your algorithm strategy and execution. We automatically provide basic portfolio management and reality modeling underneath the hood. The `QCAlgorithm` class provides some key helper properties for you to use, including the Security Manager, Portfolio Manager, Transactions Manager, Notification Manager, and Scheduling Manager. The class also has hundreds of helper methods to make the API easy to use.

The Securities property is a dictionary of `Security` objects. Each asset (Equity, Forex pair, etc) in your algorithm has a `Security` object. All the models for a security live on these objects. For example, `self.Securities["IBM"].FeeModel` and `self.Securities["IBM"].Price` return the fee model and price of IBM, respectively.

The Portfolio is a dictionary of `SecurityHolding` objects. These classes track the profits, losses, fees, and quantity of individual portfolio holdings. For example, `self.Portfolio["IBM"].LastTradeProfit` returns the profit of your last IBM trade.

Other helpers like Transactions , Schedule , Notify , and Universe have their own helper methods.

```
class QCAlgorithm:
    Securities   # Array of Security objects.
    Portfolio    # Array of SecurityHolding objects
    Transactions # Transactions helper
    Schedule     # Scheduling helper
    Notify       # Email, SMS helper
    Universe     # Universe helper

    # Set up Requested Data, Cash, Time Period.
    def Initialize(self) -> None:

    # Other Event Handlers
    def OnData(self, slice: Slice) -> None:
    def OnEndOfDay(self, symbol: Symbol) -> None:
    def OnEndOfAlgorithm(self) -> None:

    # Indicator Helpers
    def SMA(self, symbol: Symbol, period: int) -> SimpleMovingAverage:
```

Threads in LEAN

LEAN is multi-threaded and attempts to consume as much CPU as possible to perform given work as quickly as possible. The analysis engine loads data parallel and synchronizes it to generate the requested security information.

The client algorithm is plugged into LEAN, and has its events triggered synchronously in backtesting. The primary bottle neck to LEAN execution is executing client code.

In live trading, most events are synchronous as in backtesting, however order events are triggered immediately from the brokerage thread (asynchronously) to ensure the lowest latency. For example; a strategy using hourly data, with a limit order could fill between data bars. This fill event is triggered when it occurs in live trading.

We recommend using thread safe collections when possible, or locks around collections to ensure they are thread-safe.

Batch vs Stream Analysis

Backtesting platforms come in two general varieties, batch processing and event streaming. Batch processing backtesting is much simpler. It loads all data into an array and passes it to your algorithm for analysis. Because your algorithm has access to future data points, it is easy to introduce look-ahead bias . Most home-grown analysis tools are batch systems.

QuantConnect/LEAN is a streaming analysis system. In live trading, your algorithm receives data points one after another over time. QuantConnect models this in backtesting, streaming data to your algorithm in fast-forward mode. Because of this, you can't access price data beyond the Time Frontier . Although streaming analysis is slightly trickier to understand, it allows your algorithm to seamlessly work in backtests and live trading with no code changes.

Event Flow

When you deploy an algorithm, LEAN first calls the Initialize method. In live mode, the engine loads your holdings and open orders from your brokerage account to add data subscriptions and populate the `Securities` , `Portfolio` , and `Transactions` objects. LEAN receives the data from the subscriptions, synchronizes the data to create a timeslice , and then performs the following steps. Your algorithm can spend up to 10 minutes on each timeslice unless you call the Train method.

1. If it's a backtest, check if there are Scheduled Events in the past that didn't fire because there was no data between the previous slice and the current slice. LEAN automatically creates a Scheduled Event to call the

`OnEndOfDay` method at the end of each day.

In live mode, Scheduled Events occur in a separate thread from the algorithm manager, so they run at the correct time.

2. Update the algorithm time.
3. Update the `CurrentSlice` .
4. Cancel all open orders for securities that changed their ticker .
5. Add a `Security` object to the `Securities` collection for each new security in the universe.
6. Update the `Security` objects with the latest data.
7. Update the `Cash` objects in the CashBook with the latest data.
8. Process fill models for non-market orders.
9. Submit market on open orders to liquidate Equity Option contracts if the underlying Equity has a split warning .
10. Process margin calls .
11. If it's time to settle unsettled cash , perform settlement.
12. Call the OnSecuritiesChanged method with the latest security changes.
13. Apply dividends to the portfolio.
14. For securities that have a split warning, update their portfolio holdings and adjust their open orders to account for the split.
15. Update consolidators with the latest data.
16. Pass the `Slice` to the `OnData` method.
17. Perform universe selection .
18. Pass the `Slice` to the `Update` method of each Alpha model .
19. Pass the `Insight` objects from the Alpha model to the Portfolio Construction model .
20. Pass the `PortfolioTarget` objects from the Portfolio Construction model to each Risk Management model .
21. Pass the risk-adjusted `PortfolioTarget` objects from the Risk Management models to the Execution model .

When your algorithm stops executing, LEAN calls the `OnEndOfAlgorithm` method .

Python Support

The LEAN engine is written in C#, but you can create algorithms in C# or Python. If you program in Python, LEAN uses Python.Net to bridge between the C# engine and your algorithm. As a result of the bridge, `QCAlgorithm` class members are in camel case, not snake case. It can be slow to move from Python to C#. If you access C# objects in your Python algorithm, it's fastest to only access them once and save a reference if you need to access them again.

```py
# Do this:
security_holding = self.Portfolio[self.symbol]
avg_price = security_holding.AveragePrice
quantity = security_holding.Quantity

# Avoid this:
avg_price = self.Portfolio[self.symbol].AveragePrice
quantity = self.Portfolio[self.symbol].Quantity
```

Key Concepts

Multi-Asset Modeling

Introduction

We designed LEAN as a multi-asset platform with out-of-the-box support for multiple securities, so you can model complex portfolios like hedge funds.

Asset Portfolio

The portfolio manages the individual securities it contains. It tracks the cost of holding each security. It aggregates the performance of the individual securities in the portfolio to produce statistics like net profit and drawdown . The portfolio also holds information about each currency in its cashbook.

Cashbooks

We designed LEAN to be a multi-currency platform. LEAN can trade Forex, Cryptocurrencies, and other assets that are quoted in other currencies. A benefit of supporting multiple currencies is that as we add new asset classes from new countries, LEAN is already prepared to transact in those assets by using their quote currency. For instance, we added the India Equity market, which quotes assets in the INR currency.

The portfolio manages your currencies in its cashbook, which models the cash as a ledger of transactions. When you buy assets, LEAN uses the currencies in your cashbook to purchase the asset and pay the transaction fees. For more information about the cashbook, see Cashbook .

Buying Power

We model the margin requirements of each asset and reflect that in the buying power available to the algorithm. We source Futures margins from CME SPAN margins. Equity margin is 2x for standard margin accounts and 4x intraday for Pattern Day Trading accounts. For more information about buying power modeling, see Buying Power .

Key Concepts

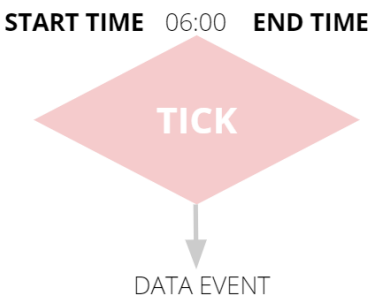
Time Modeling

Time Modeling

Periods

Introduction

Data comes in two different "shapes" according to the time period it covers: point values or period values. In QuantConnect, ticks are point values, and bars are a period values. These data formats have different properties, which control when LEAN emits them into your algorithm.



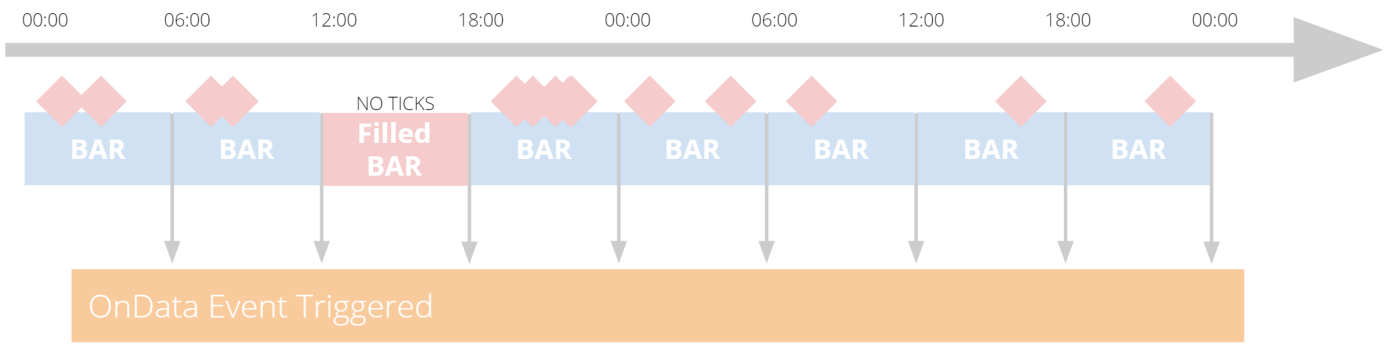
Start and End Time

Bars have a start and end time that represent the time period of which the bar aggregates data. LEAN passes the bar to your algorithm at the end time so that you don't receive the bar before it was actually available. Other data providers commonly timestamp their bars to the start time of the bar. This can cause one-off errors when you import the data into QC or compare indicator values across different platforms.

Period Values

Bars aggregate data across a period of time into a single object. We make this easy for you by pre-aggregating billions of raw trade-ticks into `TradeBar` objects and quote-ticks into `QuoteBar` objects.

We don't know the close of a bar until the start of the next bar, which can sometimes be confusing. For example, a price bar for Friday will include all the ticks from Friday 00:00:00 to Friday 23:59:59.99999, but LEAN will emit it to your algorithm on Saturday at midnight. As a result, if you analyze the Friday data and then place an order, LEAN sends the order to your brokerage on Saturday.



When there are no ticks during a period, LEAN emits the previous bar. This is the default behavior for bar data and it's referred to as "filling the data forward". You can enable and disable this setting when you create the security subscription .

We provide bar data in second, minute, hour, and daily bar formats. To create other periods of bars, see Consolidating Data .

Daily Periods

LEAN emits daily bars at midnight. To be notified when a security has finished trading for the day, add an `OnEndOfDay` method to your algorithm. LEAN calls this method for each security every day.

```
PY
def OnEndOfDay(self, symbol: Symbol) -> None:
    pass
```

Point Values

Point values have no period because they occur at a singular point in time. Examples of point data includes ticks, open interest, and news releases. Tick data represents a single trade or quote in the market. It's a discrete event with no period, so the `Time` and `EndTime` properties are the same. LEAN emits ticks as soon as they arrive and doesn't fill them forward.

Time Modeling

Timeslices

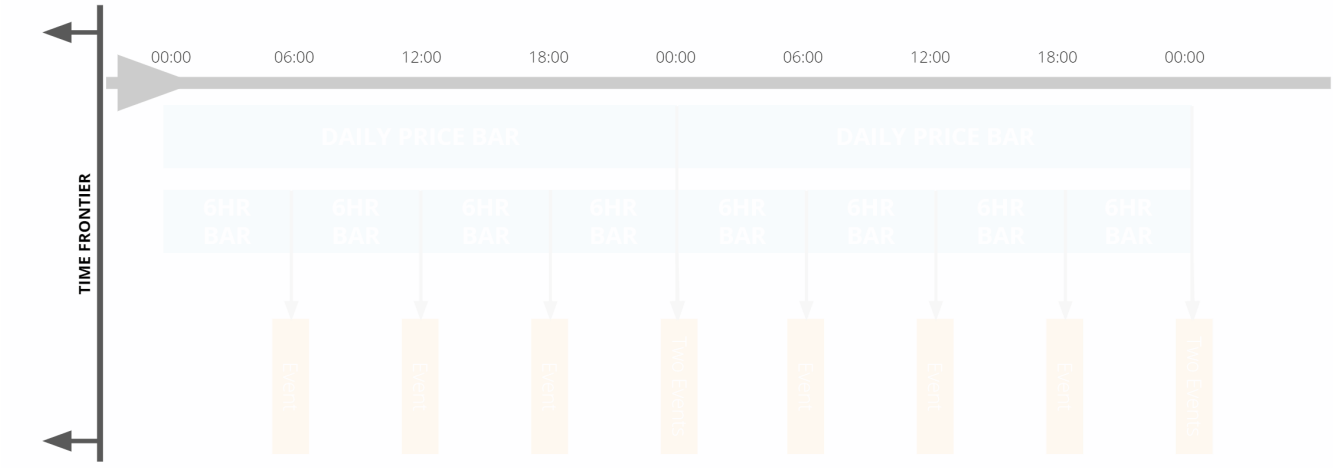
Introduction

The core technology behind QuantConnect algorithmic trading is an event-based, streaming analysis system called LEAN . LEAN attempts to model the stream of time as accurately as possible, presenting data ("events") to your algorithms in the order it arrives, as you would experience in reality.

All QuantConnect algorithms have this time-stream baked in as the primary event handler, `OnData` . The `Slice` object this method receives represents all of the data at a moment of time, a **time-slice** . No matter what data you request, you receive it in the order created according to simulated algorithm time. By only letting your algorithm see the present and past moments, we can prevent the most common quantitative-analysis error, look-ahead bias .

Time Frontier

If you request data for multiple securities and multiple resolutions, it can create a situation where one of your data subscriptions is ready to emit, but another subscription with a longer period is still be constructing its bar. Furthermore, if you request multiple datasets that have different time zones, your algorithm will receive the daily bars of each dataset at midnight in the respective time zone. To coordinate the data in these situations, we use the `EndTime` of each data point to signal when LEAN should transmit it to your algorithm.



Once your algorithm reaches the `EndTime` of a data point, LEAN sends the data to your `OnData` method. For bar data, this is the beginning of the next period. To avoid look-ahead bias, you can only access data from before this Time Frontier. The `Time` property of your algorithm is always equal to the Time Frontier.

Properties

`Slice` objects have the following properties:

Get Time Slices

To get the current `Slice` object, define an `OnData` method or use the `CurrentSlice` property of your algorithm. The

`Slice` contains all the data for a given moment in time. The `TradeBars` and `QuoteBars` properties are `Symbol` /string indexed dictionaries. The `Ticks` property is a list of ticks for that moment of time, indexed by the `Symbol` . To check which data formats are available for each asset class, see the Data Formats page in the Asset Classes chapter.

The `Slice` object gives you the following ways to access your data:

- Indexing the `Slice` , which returns a dynamic object of your type.

  ```
  def OnData(self, slice: Slice) -> None:
      data = slice[self.symbol]
  ```

  With minute and second resolution data, the dynamic type is `TradeBar` for Equities and `QuoteBar` for other asset classes.

- Indexing the static properties, which returns the type you specify.

  ```
  def OnData(self, slice: Slice) -> None:
      trade_bar = slice.Bars[self.symbol]
      quote_bar = slice.QuoteBars[self.symbol]
  ```

Check if the `Slice` contains the data you're looking for before you index it. If there is little trading, or you are in the same time loop as when you added the security, it may not have any data. Even if you enabled fill-forward for a security subscription, you should check if the data exists in the dictionary before you try to index it. To check if the `Slice` contains for a security, call the `ContainsKey` method. Note: if the `Slice` object doesn't contain any market data but it contains auxiliary data, the `slice.ContainsKey(symbol)` method can return true while `slice[symbol]` returns `None` .

```
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.symbol) and slice[self.symbol] is not None:
        data = slice[self.symbol]
```

Time Modeling

Time Zones

Introduction

LEAN is an international trading engine, so it can operate across time zones. The exchange, your algorithm, and the data in your algorithm can all have different time zones.

Exchange Time Zone

Exchanges are located in different areas, so they can have different time zones. To get the time zone of the exchange that a `Security` trades on, use its `Exchange.Hours.TimeZone` property.

```
PY
time_zone = self.Securities[self.symbol].Exchange.Hours.TimeZone
```

Algorithm Time Zone

LEAN supports international trading across multiple time zones and markets, so it needs a reference time zone for the algorithm to set the `Time` . The default time zone is Eastern Time (ET), which is UTC-4 in summer and UTC-5 in winter. To set a different time zone, call the `SetTimeZone` method. This method accepts either a string following the IANA Time Zone database convention or a NodaTime .DateTimeZone object. If you pass a string, the method converts it to a `NodaTime.DateTimeZone` object. The `TimeZones` class provides the following helper attributes to create `NodaTime.DateTimeZone` objects:

```
PY
self.SetTimeZone("Europe/London")
self.SetTimeZone(TimeZones.Chicago)
```

To get the time zone of your algorithm, use the `TimeZone` property.

```
PY
time_zone = self.TimeZone
```

To get the algorithm time in Coordinated Universal Time (UTC), use the `UtcTime` property.

```
PY
utc_time = self.UtcTime
```

The `Time` and `UtcTime` objects have no time zone. LEAN maintains their state to be consistent.

Data Time Zone

Datasets can have different time zones because the time zone is up to the data provider, where they are located, and where they collect the data. LEAN tracks the time zone of each dataset so that you receive the correct data at the right

point in time in your algorithm. If you have multiple datasets in your algorithm from different time zones, LEAN synchronizes them to your algorithm time. Furthermore, if you set up time period consolidators , LEAN consolidates the data based on the data time zone.

To get the time zone of a dataset, view the listing page in the Dataset Market or call the `GetDataTimeZone` method.

```
time_zone = self.MarketHoursDatabase.GetDataTimeZone(Market.USA, self.symbol, SecurityType.Equity)
```

Key Concepts

Security Identifiers

Introduction

We implemented `Symbol` objects in the LEAN open-source project as a way to identify or "finger-print" tradable assets so that no further database look-up is required. All QuantConnect and LEAN Algorithm API methods use `Symbol` objects to identify assets.

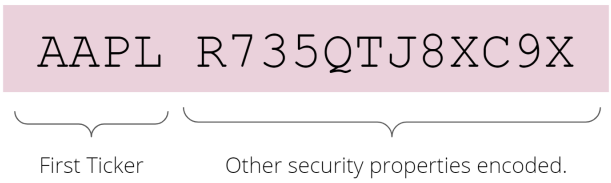
Encoding Symbols

`SecurityIdentifier` objects have several public properties to uniquely identify each asset. The following table describes these properties:

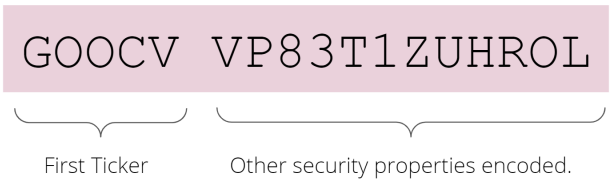
Property	Data Type	Description
`Market`	`string`	The market in which the asset trades
`SecurityType`	`SecurityType`	The asset class
`OptionStyle`	`OptionStyle`	American or European Option style
`OptionRight`	`OptionRight`	Call or put Option type
`StrikePrice`	`decimal`	The Option contract strike price
`Date`	`datetime`	Earliest listing date for Equities; expiry for Futures and Options; December 30, 1899 for continuous Futures contracts and Indices.
`HasUnderlying`	`bool`	A flag to represent if its a derivative asset with another underlying asset

We encode the preceding properties to create `Symbol` objects. We do our best to hide the details of this process from your algorithm, but you'll occasionally see it come through as an encoded hash like `AAPL R735QTJ8XC9X` . The first half of the encoded string represents the first ticker AAPL was listed under. The other letters at the end of the string represent the serialized form of the preceding `SecurityIdentifier` properties. You may also see an encoded has like `AAPL XL7X5I241SO6|AAPL R735QTJ8XC9X` for a derivative contract. In this case, the part before the `|` is contract hash and the part after the `|` is the underlying hash. This serialization approach lets LEAN assign a short, unique string to octillions of different security objects.

Apple Inc. (same name since listed).



Google Class-C Shares (renamed to GOOG).



LEAN assumes the ticker you pass to the AddEquity method is the current ticker of the Equity asset. To access this ticker, use the `Value` property of the `Symbol` object.

```py
self.symbol = self.AddEquity("GOOG").Symbol
self.Debug(self.symbol.ID.Value) # Prints "GOOCV"
self.Debug(self.symbol.Value)    # Prints "GOOG"
```

If you create the security subscription with a universe selection function, the `Value` property of the `Symbol` object is the point-in-time ticker.

Decoding Symbols

When a `SecurityIdentifier` is serialized to a string, it looks something like `SPY R735QTJ8XC9X` . This two-part string is a base64 encoded set of data. Encoding all of the properties into a short format allows dense communication without requiring a third-party list or look-up. Most of the time, you will not need to work with these encoded strings. However, to deserialize the string into a `Symbol` object, call the `Symbol` method.

```py
symbol = self.Symbol("GOOCV VP83T1ZUHROL")
symbol.ID.Market     # => "USA"
symbol.SecurityType  # => SecurityType.Equity
symbol.Value         # => "GOOCV"
```

The `Market` property distinguishes between tickers that have the same string value but represent different underlying assets. A prime example of this is the various market makers who have different prices for EURUSD. We store this data separately and as they have different fill prices, we treat the execution venues as different markets.

Tickers

Tickers are a string shortcode representation for an asset. Some examples of popular tickers include "AAPL" for Apple Corporation and "IBM" for International Business Machines Corporation. These tickers often change when the company rebrands or they undergo a merger or reverse merger.

The ticker of an asset is not the same as the `Symbol` . `Symbol` objects are permanent and track the underlying entity. When a company rebrands or changes its name, the `Symbol` object remains constant, giving algorithms a way to reliably track assets over time.

Tickers are also often reused by different brokerages. For example Coinbase, a leading US Crypto Brokerage lists the "BTCUSD" ticker for trading. Its competitor, Bitfinex, also lists "BTCUSD". You can trade both tickers with LEAN. `Symbol` objects allow LEAN to identify which market you reference in your algorithms.

To create a `Symbol` object for a point-in-time ticker, call the `GenerateEquity` method to create the security identifier and then call the `Symbol` constructor. For example, Heliogen, Inc. changed their ticker from ATHN to HLGN on December 31, 2021. To convert the ATHN ticker to the Equity `Symbol` , type:

```
PY
ticker = "ATHN"
security_id = SecurityIdentifier.GenerateEquity(ticker, Market.USA, mappingResolveDate=datetime(2021, 12,
1))
symbol = Symbol(security_id, ticker)
```

In the preceding code snippet, the `mappingResolveDate` must be a date when the point-in-time ticker was trading.

Symbol Cache

To make using the API easier, we have built the **Symbol Cache** technology, which accepts strings and tries to guess which `Symbol` object you might mean. With the Symbol Cache, many methods can accept a string such as "IBM" instead of a complete `Symbol` object. We highly recommend you don't rely on this technology and instead save explicit references to your securities when you need them.

```
PY
# Example 1: Relying On Symbol Cache:
self.AddEquity("IBM")         # Add by IBM string ticker, save reference to Symbol Cache.
self.MarketOrder("IBM", 100)  # Determine refering to IBM Equity from Symbol Cache.
self.History("AAPL", 14)      # Makes a guess referring to AAPL Equity.

# Example 2: Correctly Using Symbols:
self.ibm = self.AddEquity("IBM").Symbol   # Add IBM Equity string ticker, save Symbol.
self.MarketOrder(self.ibm, 100)           # Use IBM Symbol in future API calls.

self.aapl = Symbol.Create("AAPL", SecurityType.Equity, Market.USA)
self.History(self.aapl, 14)
```

Industry Standard Identifiers

You can convert industry-standard security identifiers like CUSIP, FIGI, ISIN, and SEDOL to `Symbol` objects and you can convert `Symbol` objects to industry-standard security identifiers.

CUSIP

To convert a Committee on Uniform Securities Identification Procedures (CUSIP) number to a `Symbol` or a `Symbol` to a CUSIP number, call the `CUSIP` method.

```
PY
symbol = self.CUSIP("03783310") # AAPL Symbol
cusip = self.CUSIP(symbol) # AAPL CUSIP (03783310)
```

FIGI

To convert a Financial Instrument Global Identifier (FIGI) to a `Symbol` or a `Symbol` to a FIGI, call the `CompositeFIGI` method.

```
symbol = self.CompositeFIGI("BBG000B9XRY4") # AAPL Symbol
figi = self.CompositeFIGI(symbol) # AAPL FIGI (BBG000B9XRY4)
```

ISIN

To convert an International Securities Identification Number (ISIN) to a `Symbol` or a `Symbol` to an ISIN, call the `ISIN` method.

```
symbol = self.ISIN("US0378331005") # AAPL Symbol
isin = self.ISIN(symbol) # AAPL ISIN (US0378331005)
```

SEDOL

To convert a Stock Exchange Daily Official List (SEDOL) number to a `Symbol` or a `Symbol` to a SEDOL number, call the `SEDOL` method.

```
symbol = self.SEDOL("2046251") # AAPL Symbol
sedol = self.SEDOL(symbol) # AAPL SEDOL (2046251)
```

Key Concepts

Event Handlers

Introduction

Event handlers are called during an algorithm execution to pass information to your strategy. Most of the events are not needed for simple strategies, but can be helpful for debugging issues in more complex algorithms.

Data Events

```py
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.symbol):
        my_data = slice[self.symbol]
```

The `OnData` method is the primary event handler for receiving financial data events to your algorithm. It is triggered sequentially at the point in time the data is available; in backtesting and live. For daily data this means the event is processed at midnight in backtesting or 6am the following day in live trading.

All data for a given moment of time is grouped in a single event, including custom data types. This data is passed with the Slice object.

When fill-forward is enabled for your asset, the OnData event handler will be called regularly even if there was no new data. This is the default behavior.

In backtesting, if your algorithm takes a long time to process a slice, the following slice objects queue up and the next event triggers when your algorithm finishes processing the current slice. In live trading, if your algorithm takes longer to process the current slice than the time period that the slice spans, the next event triggers when your algorithm finishes processing the current slice, but the slice of the following event is the most recent slice. For example, say your algorithm consumes second resolution Crypto data but it takes your algorithm 3.5 seconds to process each slice. In backtesting, you'll get every slice. In live trading, if you deploy at 12:00:00 AM Coordinated Universal Time (UTC), you'll get the first slice at 12:00:01 AM UTC (spanning 12:00:00 AM UTC to 12:00:01 AM UTC) and you'll get the second slice at 12:00:04.5 AM UTC (roughly spanning 12:00:03 AM UTC to 12:00:04 AM UTC).

To perform intensive computation before the market opens, use a Scheduled Event or the Train method.

For more information on the `Slice` object and OnData event, see Handling Data .

Securities Changed Event

```
def OnSecuritiesChanged(self, changes: SecurityChanges) -> None:
    for security in changes.AddedSecurities:
        self.Debug(f"{self.Time}: Added {security.Symbol}")

    for security in changes.RemovedSecurities:
        self.Debug(f"{self.Time}: Removed {security.Symbol}")

        if security.Invested:
            self.Liquidate(security.Symbol, "Removed from Universe")
```

The `OnSecuritiesChanged` event notifies the algorithm when assets are added or removed from the universe. This can be due to changes in the Universe constituents , or an explicit call to the RemoveSecurity method.

The event is triggered immediately when the asset is removed from the universe; however the data feed for the asset may remain active if the algorithm has open orders.

For more information, see how to use Security Changed Events .

Order Events

```
def OnOrderEvent(self, orderEvent: OrderEvent) -> None:
    order = self.Transactions.GetOrderById(orderEvent.OrderId)
    if orderEvent.Status == OrderStatus.Filled:
        self.Debug(f"{self.Time}: {order.Type}: {orderEvent}")

def OnAssignmentOrderEvent(self, assignmentEvent: OrderEvent) -> None:
    self.Log(str(assignmentEvent))
```

The `OnOrderEvent` method notifies the algorithm of new orders, and changes in the order status such as fill events and cancelations. For options assignment events there is a dedicated event handler `OnAssignmentOrderEvent` .

In backtesting order events are triggered synchronously after the main data events. In live trading, order events are asynchronously as they occur. To avoid infinite loops, we recommend not to place orders in the OnOrderEvent.

For more information, see how to use Order Events .

Brokerage Events

```
def OnBrokerageMessage(self, message: BrokerageMessageEvent) -> None:
    if message.Type == BrokerageMessageType.Reconnect:
        self.Log(f"{self.Time}: {message.Type}: Message: {message.Message}")

def OnBrokerageDisconnect(self) -> None:
    self.Log("Brokerage disconnection detected")
```

The `OnBrokerageDisconnect` and `OnBrokerageReconnect` event handlers pass information to the algorithm about the brokerage connection status. This can be helpful for considering when to place a trade when a brokerage API is unreliable or under maintenance. The `OnBrokerageMessage` event handler provides information from the brokerages, including the disconnect and reconnect messages. Message content varies with each brokerage.

Brokerage events are triggered asynchronously in live trading, and are not created in backtesting.

Margin Call Events

```
def OnMarginCall(self, requests): -> List[SubmitOrderRequest]:
    # Modify order requests to choose what to liquidate.
    return requests

def OnMarginCallWarning()(self) -> None:
    self.Log("Margin call warning, 5% margin remaining")
```

The `OnMarginCallWarning` and `OnMarginCall` event handlers provide information and control over how to reduce algorithm leverage when performance is poor.

The `OnMarginCallWarning` method is called when there is less than 5% margin remaining, this gives you an opportunity to reduce leverage before an official margin call is performed by the brokerage. The `OnMarginCall` event handler is passed a list of `SubmitOrderRequest` objects which will be executed on exiting the method.

Margin events are called before the data events are processed.

The following demonstration processes suggested orders and modifies the qualities to liquidate more than necessary and prevent a second margin call. For more information, see how to handle Margin Calls .

Warmup Finished Event

```
def OnWarmupFinished(self) -> None:
    pass # Done warming up
```

The `OnWarmupFinished` event handler is triggered after initialization, and warm up is complete. This event signals that the initialization of the algorithm is complete.

For more information, see how to use Warm Up to prepare your algorithm.

End Of Algorithm Events

```
def OnEndOfAlgorithm(self) -> None:
    self.Debug("Algorithm done")
```

The `OnEndOfAlgorithm` event handler is when the algorithm has finished executing as its final step. This is helpful for performing final analysis, or saving algorithm state.

Event Flow

When you deploy an algorithm, LEAN first calls the Initialize method. In live mode, the engine loads your holdings and open orders from your brokerage account to add data subscriptions and populate the `Securities` , `Portfolio` , and `Transactions` objects. LEAN receives the data from the subscriptions, synchronizes the data to create a timeslice , and then performs the following steps. Your algorithm can spend up to 10 minutes on each timeslice unless you call the Train method.

1. If it's a backtest, check if there are Scheduled Events in the past that didn't fire because there was no data between the previous slice and the current slice. LEAN automatically creates a Scheduled Event to call the `OnEndOfDay` method at the end of each day.

In live mode, Scheduled Events occur in a separate thread from the algorithm manager, so they run at the correct time.

2. Update the algorithm time.
3. Update the `CurrentSlice` .
4. Cancel all open orders for securities that changed their ticker .
5. Add a `Security` object to the `Securities` collection for each new security in the universe.
6. Update the `Security` objects with the latest data.
7. Update the `Cash` objects in the CashBook with the latest data.
8. Process fill models for non-market orders.
9. Submit market on open orders to liquidate Equity Option contracts if the underlying Equity has a split warning .
10. Process margin calls .
11. If it's time to settle unsettled cash , perform settlement.
12. Call the OnSecuritiesChanged method with the latest security changes.
13. Apply dividends to the portfolio.
14. For securities that have a split warning, update their portfolio holdings and adjust their open orders to account for the split.
15. Update consolidators with the latest data.
16. Pass the `Slice` to the `OnData` method.
17. Perform universe selection .
18. Pass the `Slice` to the `Update` method of each Alpha model .
19. Pass the `Insight` objects from the Alpha model to the Portfolio Construction model .
20. Pass the `PortfolioTarget` objects from the Portfolio Construction model to each Risk Management model .
21. Pass the risk-adjusted `PortfolioTarget` objects from the Risk Management models to the Execution model .

When your algorithm stops executing, LEAN calls the `OnEndOfAlgorithm` method .

Key Concepts

Python and LEAN

Introduction

The LEAN open-source package powers the core functionality of QuantConnect. Strategies plugin to LEAN to request data, and process trades. LEAN is written in C# and accessed in python with a defined API. Most of these interactions are using native python types, with a few key exceptions. To comfortably use LEAN you should learn to recognize error messages when you hit a non-native API, and how to convert back to a native type.

Enumerable Types

When LEAN returns an enumerable, the object should be converted to a `list()` to be easily read by python classes. Popular API methods which return an enumerable are shown below:

Historical Data

QuantConnect also provides methods to request historical data that return a pandas dataframe, or an enumerable. If loading a large amount of data using an enumerable streams the results reducing RAM usage.

The enumerable types might look like the `MemoizingEnumerable` that is a raw C# type accessible in python.

```
qb = QuantBook()
start = datetime(2023, 2, 1)
end = datetime(2023, 2, 4)
ibm = qb.AddEquity('IBM', Resolution.Minute)
bars = qb.History[TradeBar](ibm.Symbol, start, end, Resolution.Minute)
bars
```

✓ 0.3s Python

```
<QuantConnect.Util.MemoizingEnumerable[TradeBar] object at 0x7fd5313209c0>
```

You can directly enumerate this object with standard python `for` loops, or to convert it to a native type, wrap the object in the `list()` :

```
# Loop over enumerable
import numpy as np
close = []
for bar in bars:
    close.append( bar.Close )
print( np.mean(close) )

# Manipulate as a list
barList =  list(bars)
len(barList)
```

✓ 0.8s Python

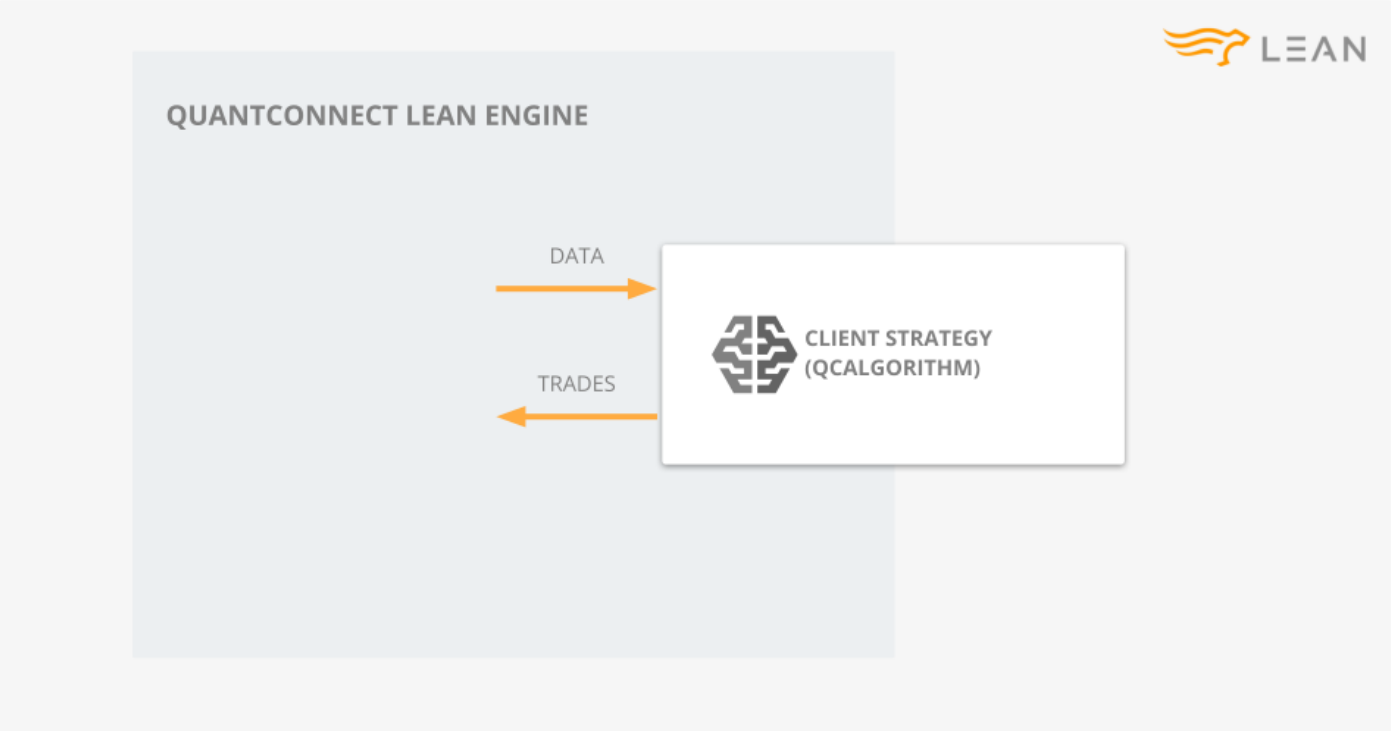
```
135.29654786324787

1170
```

Underlying Plugin Architecture

Your strategy code implements the QCAlgorithm class, which can communicate with the LEAN Engine. These method

calls are done at the same speed as cython, directly invoking calls at the C layer of python. Your algorithm is imported as syntax checked, interpreted python.



Key Concepts

Glossary

Introduction

This page defines terms in QuantConnect products and documentation.

alpha

The quantity of an algorithm's returns that aren't explained by its underlying benchmark.

annual standard deviation

A staticial measure that describes the dispersion of annual returns relative to the mean annual return. It's the square root of the annual variance.

annual variance

A staticial measure that describes the dispersion of annual returns relative to the mean annual return.

average loss

The average rate of return for unprofitable trades.

average win

The average rate of return for profitable trades.

beta

The scale and direction of an algorithm's returns relative to movements in the underlying benchmark.

capacity

The maximum amount of money an algorithm can trade before its performance degrades from market impact.

compounding annual return

The annual percentage return that would be required to grow a portfolio from its starting value to its ending value.

day trade

Buying and selling the same asset within one trading day.

drawdown

The largest peak to trough decline in an algorithm's equity curve.

equity

The total portfolio value if all of the holdings were sold at current market rates.

expectancy

The expected return per trade.

holdings

The absolute sum of the items in the portfolio.

information ratio

The amount of excess return from the risk-free rate per unit of systematic risk.

intrinsic value

(Call Option) The price of an asset minus the strike price if the price is above the strike price, otherwise zero.

(Put Option) The strike price minus the price of an asset if the price is below the strike price, otherwise zero.

look-ahead bias

The practice of making decisions using information that would not be available until some time in the future.

loss rate

The proportion of trades that were not profitable.

lowest capacity asset

The asset an algorithm traded that has the lowest capacity.

net profit

(Percent) The rate of return across the entire trading period.

(Dollar-value) The dollar-value return across the entire trading period.

out-of-the-money amount

(Call Option) The strike price minus the price of an asset if the price is below the strike price, otherwise zero.

(Put Option) The price of an asset minus the strike price if the price is above the strike price, otherwise zero.

payoff

The profit or loss that an Option buyer or seller makes from a trade.

pattern day trader

A trader who executes four or more day trades in the US Equity market within five business days.

Probabilistic Sharpe ratio

The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark (1).

profit-loss ratio

The ratio of the average win rate to the average loss rate.

return

The rate of return across the entire trading period.

Sharpe ratio

A measure of the risk-adjusted return, developed by William Sharpe.

total fees

The total quantity of fees paid for all the transactions.

total net profit

The rate of return across the entire trading period.

total trades

The number of orders that were filled or partially filled.

tracking error

A measure of how closely a portfolio follows the index to which it is benchmarked. A tracking error of 0 is a perfect match.

Treynor ratio

A measurement of the returns earned in an algorithm in excess of the risk-free rate per unit of benchmark risk, developed by Jack Treynor.

unrealized

The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread.

volume

The total value of assets traded for all of an algorithm's transactions.

win rate

The proportion of trades that were profitable after transaction fees.

Key Concepts

Research Guide

Introduction

We aim to teach and inspire our community to create high-performing algorithmic trading strategies. We measure our success by the profits community members create through their live trading. As such, we try to build the best quantitative research techniques possible into the product to encourage a robust research process.

Hypothesis-Driven Research

We recommend you develop an algorithmic trading strategy based on a central hypothesis. You should develop an algorithm hypothesis at the start of your research and spend the remaining time exploring how to test your theory. If you find yourself deviating from your core theory or introducing code that isn't based around that hypothesis, you should stop and go back to thesis development.

Wang et al. (2014) illustrate the danger of creating your hypothesis based on test results. In their research, they examined the earnings yield factor in the technology sector over time. During 1998-1999, before the tech bubble burst, the factor was unprofitable. If you saw the results and then decided to bet against the factor during 2000-2002, you would have lost a lot of money because the factor performed extremely well during that time.

Hypothesis development is somewhat of an art and requires creativity and great observation skills. It is one of the most powerful skills a quant can learn. We recommend that an algorithm hypothesis follow the pattern of cause and effect. Your aim should be to express your strategy in the following sentence:

> *A change in {cause} leads to an {effect}.*

To search for inspiration, consider causes from your own experience, intuition, or the media. Generally, causes of financial market movements fall into the following categories:

- Human psychology
- Real-world events/fundamentals
- Invisible financial actions

Consider the following examples:

Cause	*leads to*	Effect
Share class stocks are the same company, so any price divergence is irrational...		A perfect pairs trade. Since they are the same company, the price will revert.
New stock addition to the S&P500 Index causes fund managers to buy up stock...		An increase in the price of the new asset in the universe from buying pressure.
Increase in sunshine-hours increases the production of oranges...		An increase in the supply of oranges, decreasing the price of Orange Juice Futures.
Allegations of fraud by the CEO causes investor faith in the stock to fall...		A collapse of stock prices for the company as people panic.
FDA approval of a new drug opens up new markets for the pharmaceutical company...		A jump in stock prices for the company.
Increasing federal interest rates restrict lending from banks, raising interest rates...		Restricted REIT leverage and lower REIT ETF returns.

There are millions of potential alpha strategies to explore, each of them a candidate for an algorithm. Once you have chosen a strategy, we recommend exploring it for no more than 8-32 hours, depending on your coding ability.

Data Mining Driven Research

An alternative view is to follow any statistical anomaly without explaining it. In this case, you can use statistical techniques to identify the discontinuities and eliminate them when their edge is gone. Apparently, Renaissance Technologies has data mining models like this.

Overfitting

Overfitting occurs when you fine-tune the parameters of an algorithm to fit the detail and noise of backtesting data to the extent that it negatively impacts the performance of the algorithm on new data. The problem is that the parameters don't necessarily apply to new data and thus negatively impact the algorithm's ability to generalize and trade well in all market conditions. The following table shows ways that overfitting can manifest itself:

Data Practice	Description
Data Dredging	Performing many statistical tests on data and only paying attention to those that come back with significant results.
Hyper-Tuning Parameters	Manually changing algorithm parameters to produce better results without altering the test data.
Overfit Regression Models	Regression, machine learning, or other statistical models with too many variables will likely introduce overfitting to an algorithm.
Stale Testing Data	Not changing the backtesting data set when testing the algorithm. Any improvements might not be able to be generalized to different datasets.

An algorithm that is dynamic and generalizes to new data is more valuable to funds and individual investors. It is more likely to survive across different market conditions and apply to new asset classes and markets.

If you have a collection of factors, you can backtest over a period of time to find the best-performing factors for the

time period. If you then narrow the collection of factors to just the best-performing ones and backtest over the same period, the backtest will show great results. However, if you take the same best-performing factors and backtest them on an out-of-sample dataset, the performance will almost always underperform the in-sample period. To avoid issues with overfitting, follow these guidelines:

- Use walk-forward optimization to train your models on historical data and test them on future data.
- Test your strategy with live paper trading.
- Test your model on different asset classes and markets.

Look-ahead Bias

Look-ahead bias occurs when you use information from the future to inform decisions in the present. An example of look-ahead bias is using financial statement data to make trading decisions at the end of the reporting period instead of when the financial statement data was released. Another example is using updated financial statement data before the updated figures were actually available. Wang et al. (2014) show that using the date of when the period ends instead of when the data is actually available can increase the performance of the earnings yield factor by 60%.

Another culprit of look-ahead bias is adjusted price data. Splits and reverse splits can improve liquidity or attract certain investors, causing the performance of the stock to be different than without the split or reverse split. Wang et al (2014) build a portfolio using the 25 lowest priced stocks in the S&P index based on adjusted and non-adjusted prices. The portfolio based on adjusted prices greatly outperformed the one with raw prices in terms of return and Sharpe ratio . In this case, if you were to analyze the low price factor with adjusted prices, it would lead you to believe the factor is very informative, but it would not perform well out-of-sample with raw data.

Look-ahead bias can also occur if you set the universe to assets that have performed well during the backtest period or initialize indicators with values that have performed well during the backtest period. To avoid issues with look-ahead bias, trade a dynamic universe of assets and use point-in-time data. If point-in-time data is not available for the dataset you use, apply a reporting lag. Since the backtesting environment is event-driven and you can't pass the time frontier, it naturally helps to reduce the risk of look-ahead bias.

Survivorship Bias

Survivorship bias occurs when you test a strategy using only the securities that have survived to the end of the testing period and omit securities that have been delisted. If you use the current constituents of an index and backtest over the past, you'll most likely outperform the index because many of the underperformers have dropped out of the index over time and outperformers have been added to the index. In this case, the current constituent universe would consist of only outperformers. This technique is a form of look-ahead bias because if you were trading the strategy in real-time throughout the backtest period, you would not know the current index constituents until today.

If you analyze a dataset that has survivorship bias, you can discover results that are opposite of the true results. For example, Wang et al. (2014) analyze the low volatility factor using two universes. The first universe was the current S&P 500 constituents and the second universe was the point-in-time constituents. When they used the point-in-time constituents, the low volatility quintile outperformed the high volatility quintile. However, when they used the current constituents, the high volatility quintile significantly outperformed the low volatility quintile.

To avoid issues with survivorship bias, trade a dynamic universe of assets and use the datasets in the Dataset Market . We thoroughly vet the datasets we add to the market to ensure they're free of survivorship bias.

Outliers

Outliers in a dataset can have large impacts on how models train. In some cases, you may leave outliers in a dataset because they can contain useful information. In other cases, you may want to transform the data to handle the outlier data points. There are several common methods to handle outliers.

Winsorization Method

The winsorization method removes outliers at the x% of the extremes. For example, if you winsorize at 1%, it removes the 1% of data points with the lowest value and the 1% of data points with the highest value. This threshold percentage is subjective, so it can result in overfitting.

IQR Method

The interquartile range method removes data points that fall outside of the interval $[Q_1 - k(Q_3 - Q_1),\ Q_3 + k(Q_3 - Q_1)]$ for some constant $k \geq 0$. This method can exclude up to 25% of observations on each side of the extremes. The interquartile range method doesn't work if the data is skewed or non-normal. Therefore, the disadvantage to this method is you need to review the factor distribution properties. If you need to, you can normalize the data with z-scores.

$$Z = \frac{x - \mu}{\sigma}$$

Factor Ranking Method

The factor ranking method ranks the data values instead of taking their raw values. With this method, you don't need to remove any outlier data points. This method transforms the data into a uniform distribution. After converting the data to a uniform distribution, Wang et al. (2014) perform an inverse normal transformation to make the factor values normally distributed. Wang et al. found this ranking technique outperforms the z-score transformation, suggesting that the distance between factor scores doesn't add useful information.

Key Concepts

Libraries

Introduction

Libraries (or packages) are third-party software that you can use in your projects. You can use many of the available open-source libraries to complement the classes and methods that you create. Libraries reduce your development time because it's faster to use a pre-built, open-source library than to write the functionality. Libraries can be used in backtesting, research, and live trading. The environments support various libraries for machine learning, plotting, and data processing. As members often request new libraries, we frequently add new libraries to the underlying docker image that runs the Lean engine.

This feature is primarily for Python algorithms as not all Python libraries are compatible with each other. We've bundled together different sets of libraries into distinct environments. To use the libraries of an environment, set the environment in your project and add the relevant `import` statement of a library at the top of your file.

Default Environment Libraries

The default environment supports the following libraries:

```
# Name                      Version
absl-py                     1.4.0
adagio                      0.2.4
aesara                      2.8.12
aiodns                      3.0.0
aiohttp                     3.8.4
aiohttp-cors                0.7.0
aiosignal                   1.3.1
alabaster                   0.7.13
ale-py                      0.7.4
alembic                     1.10.3
alpaca-trade-api            0.26
alphalens-reloaded          0.4.3
altair                      4.2.2
ansi2html                   1.8.0
antlr4-python3-runtime      4.11.1
anyio                       3.6.2
appdirs                     1.4.4
arch                        5.3.1
argon2-cffi                 21.3.0
argon2-cffi-bindings        21.2.0
arviz                       0.15.1
astropy                     5.2.1
asttokens                   2.2.1
astunparse                  1.6.3
async-timeout               4.0.2
asyncio-nats-client         0.11.5
attrs                       23.1.0
autograd                    1.5
autokeras                   1.1.0
autoray                     0.6.3
AutoROM                     0.4.2
AutoROM.accept-rom-license  0.6.1
ax-platform                 0.3.0
Babel                       2.12.1
backcall                    0.2.0
bayesian-optimization       1.4.2
beautifulsoup4              4.11.2
bleach                      6.0.0
blessed                     1.20.0

Add New Libraries

To request a new library, contact us . We will add the library to the queue for review and deployment. Since the libraries run on our servers, we need to ensure they are secure and won't cause harm. The process of adding new libraries takes 2-4 weeks to complete. View the list of libraries currently under review on the Issues list of the Lean GitHub repository .

Project Libraries

Project libraries are QuantConnect projects you can merge into your project to avoid duplicating code files. If you have tools that you use across several projects, create a library.

Key Concepts

Glossary

Introduction

This page defines terms in QuantConnect products and documentation.

alpha

The quantity of an algorithm's returns that aren't explained by its underlying benchmark.

annual standard deviation

A staticial measure that describes the dispersion of annual returns relative to the mean annual return. It's the square root of the annual variance.

annual variance

A staticial measure that describes the dispersion of annual returns relative to the mean annual return.

average loss

The average rate of return for unprofitable trades.

average win

The average rate of return for profitable trades.

beta

The scale and direction of an algorithm's returns relative to movements in the underlying benchmark.

capacity

The maximum amount of money an algorithm can trade before its performance degrades from market impact.

compounding annual return

The annual percentage return that would be required to grow a portfolio from its starting value to its ending value.

day trade

Buying and selling the same asset within one trading day.

drawdown

The largest peak to trough decline in an algorithm's equity curve.

equity

The total portfolio value if all of the holdings were sold at current market rates.

expectancy

The expected return per trade.

holdings

The absolute sum of the items in the portfolio.

information ratio

The amount of excess return from the risk-free rate per unit of systematic risk.

look-ahead bias

The practice of making decisions using information that would not be available until some time in the future.

loss rate

The proportion of trades that were not profitable.

lowest capacity asset

The asset an algorithm traded that has the lowest capacity.

net profit

(Percent) The rate of return across the entire trading period.

(Dollar-value) The dollar-value return across the entire trading period.

pattern day trader

A trader who executes four or more day trades in the US Equity market within five business days.

Probabilistic Sharpe ratio

The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark (1).

profit-loss ratio

The ratio of the average win rate to the average loss rate.

return

The rate of return across the entire trading period.

Sharpe ratio

A measure of the risk-adjusted return, developed by William Sharpe.

total fees

The total quantity of fees paid for all the transactions.

total net profit

The rate of return across the entire trading period.

total trades

The number of orders that were filled or partially filled.

tracking error

A measure of how closely a portfolio follows the index to which it is benchmarked. A tracking error of 0 is a perfect match.

Treynor ratio

A measurement of the returns earned in an algorithm in excess of the risk-free rate per unit of benchmark risk, developed by Jack Treynor.

unrealized

The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread.

volume

The total value of assets traded for all of an algorithm's transactions.

win rate

The proportion of trades that were profitable after transaction fees.

Initialization

Introduction

The `Initialize` method is the entry point of your algorithm where you define a series of settings, including security subscriptions, starting cash balances, and warm-up periods. LEAN only calls the `Initialize` method one time, at the start of your algorithm.

Set Dates

To set the date range of backtests, call the `SetStartDate` and `SetEndDate` methods. The dates you provide are based in the algorithm time zone. By default, the end date is yesterday, one millisecond before midnight. In live trading, LEAN ignores the start and end dates.

```
PY
self.SetStartDate(2013, 1, 5)                  # Set start date to January 5, 2013
self.SetEndDate(2015, 1, 5)                    # Set end date to January 5, 2015
self.SetEndDate(datetime.now() - timedelta(7)) # Set end date to last week
```

Set Account Currency

The algorithm equity curve, benchmark, and performance statistics are denominated in the account currency. To set the account currency and your starting cash, call the `SetAccountCurrency` method. By default, the account currency is USD and your starting cash is $100,000. If you call the `SetAccountCurrency` method, you must call it before you call the `SetCash` method or add data . If you call the `SetAccountCurrency` method more than once, only the first call takes effect.

```
PY
self.SetAccountCurrency("BTC") # Set account currency to Bitcoin and its quantity to 100,000 BTC
self.SetAccountCurrency("INR") # Set account currency to Indian Rupees and its quantity to 100,000 INR
self.SetAccountCurrency("BTC", 10);  // Set account currency to Bitcoin and its quantity to 10 BTC
```

Set Cash

To set your starting cash in backtests, call the `SetCash` method. By default, your starting cash is $100,000 USD. In live trading, LEAN ignores the `SetCash` method and uses the cash balances in your brokerage account instead.

```
PY
self.SetCash(100000)       # Set the quantity of the account currency to 100,000
self.SetCash("BTC", 10)    # Set the Bitcoin quantity to 10
self.SetCash("EUR", 10000) # Set the EUR quantity to 10,000
```

Set Brokerage and Cash Model

We model your algorithm with margin modeling by default, but you can select a cash account type. Cash accounts don't allow leveraged trading, whereas Margin accounts can support leverage on your account value. To set your brokerage and account type, call the `SetBrokerageModel` method. For more information about each brokerage and the account

types they support, see the brokerage integration documentation. For more information about the reality models that the brokerage models set, see Supported Models .

```
self.SetBrokerageModel(BrokerageName.InteractiveBrokersBrokerage, AccountType.Cash)
```

PY

The `AccountType` enumeration has the following members:

Set Universe Settings

The universe settings of your algorithm configure some properties of the universe constituents. The following table describes the properties of the `UniverseSettings` object:

Property: `ExtendedMarketHours` Should assets also feed extended market hours? You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily resolution, the daily bars only reflect the regular trading hours. Data Type: `bool` | Default Value: `False`
Property: `FillForward` Should asset data fill forward? Data Type: `bool` | Default Value: `True`
Property: `MinimumTimeInUniverse` What's the minimum time assets should be in the universe? Data Type: `timedelta` | Default Value: `timedelta(1)`
Property: `Resolution` What resolution should assets use? Data Type: `Resolution` | Default Value: `Resolution.Minute`

Property: `ContractDepthOffset` What offset from the current front month should be used for continuous Future contracts ? 0 uses the front month and 1 uses the back month contract. This setting is only available for Future assets. Data Type: `int` | Default Value: `0`
Property: `DataMappingMode` How should continuous Future contracts be mapped? This setting is only available for Future assets. Data Type: `DataMappingMode` | Default Value: `DataMappingMode.OpenInterest`
Property: `DataNormalizationMode` How should historical prices be adjusted? This setting is only available for Equity and Futures assets. Data Type: `DataNormalizationMode` | Default Value: `DataNormalizationMode.Adjusted`
Property: `Leverage` What leverage should assets use in the universe? This setting is not available for derivative assets. Data Type: `float` | Default Value: `Security.NullLeverage`

To set the `UniverseSettings` , update the preceding properties in the `Initialize` method before you add the "universe" These settings are globals, so they apply to all universes you create.

```
# Request second resolution data. This will be slow!
self.UniverseSettings.Resolution = Resolution.Second
self.AddUniverse(self.MyCoarseFilterFunction)
```

Set Security Initializer

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `Initialize` method, call the `SetSecurityInitializer` method and then define the security initializer.

```py
#In Initialize
self.SetSecurityInitializer(self.CustomSecurityInitializer)

def CustomSecurityInitializer(self, security: Security) -> None:
    # Disable trading fees
    security.SetFeeModel(ConstantFeeModel(0, "USD"))
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```py
self.SetSecurityInitializer(lambda security: security.SetFeeModel(ConstantFeeModel(0, "USD")))
```

In some cases, you may want to trade a security in the same time loop that you create the security subscription. To avoid errors, use a security initializer to set the market price of each security to the last known price. The `GetLastKnownPrices` method seeds the security price by gathering the security data over the last 3 days. If there is no data during this period, the security price remains at 0.

```py
seeder = FuncSecuritySeeder(self.GetLastKnownPrices)
self.SetSecurityInitializer(lambda security: seeder.SeedSecurity(security))
```

If you call the `SetSecurityInitializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, create a custom `BrokerageModelSecurityInitializer` .

```
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetFeeModel(ConstantFeeModel(0, "USD"))
```

To set a seeder function without overwriting the reality models of the brokerage, use the standard `BrokerageModelSecurityInitializer`.

```
self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))
```

Add Data

You can subscribe to asset, fundamental, alternative, and custom data. The Dataset Market provides 400TB of data that you can easily import into your algorithms.

Asset Data

To subscribe to asset data, call one of the asset subscription methods like `AddEquity` or `AddForex`. Each asset class has its own method to create subscriptions. For more information about how to create subscriptions for each asset class, see Asset Classes.

```
self.AddEquity("SPY")  # Add Apple 1 minute bars (minute by default)
self.AddForex("EURUSD", Resolution.Second) # Add EURUSD 1 second bars
```

In live trading, you define the securities you want, but LEAN also gets the securities in your live portfolio and sets their resolution to the lowest resolution of the subscriptions you made. For example, if you create subscriptions in your algorithm for securities with Second, Minute, and Hour resolutions, the assets in your live portfolio are given a resolution of Second.

Alternative Data

To add alternative datasets to your algorithms, call the `AddData` method. For full examples, in the Datasets chapter, select a dataset and see the **Requesting Data** section.

Custom Data

To add custom data to your algorithms, call the `AddData` method. For more information about custom data, see Importing Data.

Limitations

There is no official limit to how much data you can add to your algorithms, but there are practical resource limitations. Each security subscription requires about 5MB of RAM, so larger machines let you run algorithms with bigger universes. For more information about our cloud nodes, see Resources .

Set Indicators and Consolidators

You can create and warm-up indicators in the `Initialize` method.

```
self.symbol = self.AddEquity("SPY").Symbol
self.sma = self.SMA(self.symbol, 20)
self.WarmUpIndicator(self.symbol, self.sma)
```

PY

Set Algorithm Settings

The following table describes the `AlgorithmSettings` properties:

Property: `DataSubscriptionLimit` The maximum number of concurrent market data subscriptions available. Data Type: `Int` | Default Value: `int.MaxValue`
Property: `FreePortfolioValue` The buying power buffer value. Data Type: `float` | Default Value: `250`
Property: `FreePortfolioValuePercentage` The buying power buffer percentage value. Data Type: `float` | Default Value: `0.0025`
Property: `LiquidateEnabled` A flag to enable and disable the `Liquidate` method. Data Type: `bool` | Default Value: `True`

Property: `MaxAbsolutePortfolioTargetPercentage`

The absolute maximum valid total portfolio value target percentage.

Data Type: `float` | Default Value: `1000000000`

Property: `MinAbsolutePortfolioTargetPercentage`

The absolute minimum valid total portfolio value target percentage.

Data Type: `float` | Default Value: `0.0000000001`

Property: `MinimumOrderMarginPortfolioPercentage`

The minimum order margin portfolio percentage to ignore bad orders and orders with small sizes.

Data Type: `float` | Default Value: `0.001`

Property: `RebalancePortfolioOnInsightChanges`

Rebalance the portfolio when you emit new insights or when insights expire.

Data Type: `bool/NoneType` | Default Value: `True`

Property: `RebalancePortfolioOnSecurityChanges`

Rebalance the portfolio when your universe changes.

Data Type: `bool/NoneType` | Default Value: `True`

Property: `StalePriceTimeSpan`

The minimum time span elapsed to consider a market fill price as stale

Data Type: `timedelta` | Default Value: `timedelta(hours=1)`

Property: `WarmUpResolution`

The resolution to use during the warm-up period

Data Type: `Resolution/NoneType` | Default Value: `None`

To change the `AlgorithmSettings` , update some of the preceding properties.

```
self.Settings.RebalancePortfolioOnSecurityChanges = False
```

To successfully update the `FreePortfolioValue` , you must update it after the `Initialize` method.

Set Benchmark

The benchmark performance is input to calculate several statistics on your algorithm, including alpha and beta . To set a benchmark for your algorithm, call the `SetBenchmark` method. You can set the benchmark to a security, a constant value, or a value from a custom data source . If you don't set a brokerage model , the default benchmark is SPY. If you set a brokerage model, the model defines the default benchmark.

```
# Set the benchmark to IBM
self.SetBenchmark("IBM")

# Set the benchmark to a constant value of 0
self.SetBenchmark(lambda x: 0)

# Set the benchmark to a value from a custom data source
self.symbol = self.AddData(CustomData, "CustomData", Resolution.Hour).Symbol
self.SetBenchmark(self.symbol)
```

If you pass a ticker to the `SetBenchmark` method, LEAN checks if you have a subscription for it. If you have a subscription for it, LEAN uses the security subscription. If you don't have a subscription for it, LEAN creates a US Equity subscription with the ticker. Since the ticker you pass may not reference a US Equity, we recommend you subscribe to the benchmark security before you call the `SetBenchmark` method.

Set Time Zone

LEAN supports international trading across multiple time zones and markets, so it needs a reference time zone for the algorithm to set the `Time` . The default time zone is Eastern Time (ET), which is UTC-4 in summer and UTC-5 in winter. To set a different time zone, call the `SetTimeZone` method. This method accepts either a string following the IANA Time Zone database convention or a NodaTime .DateTimeZone object. If you pass a string, the method converts it to a `NodaTime.DateTimeZone` object. The `TimeZones` class provides the following helper attributes to create `NodaTime.DateTimeZone` objects:

```
self.SetTimeZone("Europe/London")
self.SetTimeZone(TimeZones.Chicago)
```

The algorithm time zone may be different from the data time zone . If the time zones are different, it might appear like there is a lag between the algorithm time and the first bar of a history request, but this is just the difference in time zone. All the data is internally synchronized in Coordinated Universal Time (UTC) and arrives in the same Slice object. A slice is a sliver of time with all the data available for this moment.

To keep trades easy to compare between asset classes, we mark all orders in UTC time.

Set Warm Up Period

You may need some historical data at the start of your algorithm to prime technical indicators or populate historical data arrays. The warm-up period pumps data into your algorithm from before the start date. To set a warm-up period, call the `SetWarmUp` method. The warm-up feature uses the subscriptions you add in `Initialize` to gather the historical data that warms up the algorithm. If you don't create security subscriptions in the `Initialize` method, the warm-up won't occur.

```
PY
# Wind time back 7 days from the start date
self.SetWarmUp(timedelta(7))

# Feed in 100 trading days worth of data before the start date
self.SetWarmUp(100, Resolution.Daily)

# If you don't provide a resolution argument, it uses the lowest resolution in your subscriptions
self.SetWarmUp(100)
```

Post Initialization

After the `Initialize` method, the `PostInitialize` method performs post-initialization routines, so don't override it. To be notified when the algorithm is ready to begin trading, define an `OnWarmupFinished` method. This method executes even if you don't set a warm-up period.

```
PY
def OnWarmupFinished(self) -> None:
    self.Log("Algorithm Ready")
```

Securities

Securities

Key Concepts

Introduction

A security is an individual financial asset that you might trade on an exchange. LEAN models these unique assets with a `Security` object, which the `AddEquity` , `AddCrypto` , and similar methods return. The `Securities` property of the `QCAlgorithm` class is a dictionary where the keys are `Symbol` objects and the values are `Security` objects. The `Securities` dictionary contains all of the securities that have been in the algorithm during its lifetime.

Quote Currency

The quote currency is the currency you must give the seller to buy an asset. For currency trades, the quote currency is the currency ticker on the right side of the currency pair. For other types of assets, the quote currency is usually USD, but the quote currency for India Equities is INR. To get the quote currency of a `Security` , use the `QuoteCurrency` property.

```
aapl_quote_currency = self.Securities["AAPL"].QuoteCurrency # USD
btcusdt_quote_currency = self.Securities["BTCUSDT"].QuoteCurrency # USDT
```

The `QuoteCurrency` is a `Cash` object, which have the following properties:

You can use the `ConversionRate` property to calculate the value of the minimum price movement in the account currency

```
cfd = self.Securities["SG30SGD"]
quote_currency = cfd.QuoteCurrency # SGD
contract_mutiplier = cfd.SymbolProperties.ContractMultiplier
minimum_price_variation = cfd.SymbolProperties.MinimumPriceVariation

# Value of a pip in account currency
pip = minimum_price_variation * contract_mutiplier * quote_currency.ConversionRate
```

Security Listing

The `Exchange` property of a `Security` object contains information about the exchange that lists the security.

```
exchange = self.Securities["SPY"].Exchange
```

Security Market

The `Market` enumeration has the following members:

LEAN groups all of the US Equity exchanges under `Market.USA` . In live mode, the brokerage routes the orders to the exchange that provides the best price.

Active Securities

The `ActiveSecurities` property of the algorithm class contains all of the assets currently in your universe. It is a dictionary where the key is a `Symbol` and the value is a `Security` . When you remove an asset from a universe, LEAN usually removes the security from the `ActiveSecurities` collection and removes the security subscription. However, it won't remove the security in any of the following situations:

- You own the security.
- You have an open order for the security.
- The security wasn't in the universe long enough to meet the `MinimumTimeInUniverse` setting.

When LEAN removes the security, the `Security` object remains in the `Securities` collection for record-keeping purposes, like tracking fees and trading volume.

Tradable Status

The `IsTradable` property shows whether you can trade a security. The property value is true when the security is in the universe, even if the data starts at a later day. Indices, canonical Option securities, and continuous Futures contracts are not tradable. In live mode, custom data objects are also not tradable, even if the custom data represents a tradable asset.

```
tradable = self.Securities["SPY"].IsTradable
```
PY

Linked Custom Data

Linked custom data is custom data that's linked to individual assets. In contrast, unlinked data is not linked to specific assets. An example of an unlinked dataset is the US Regulatory Alerts dataset. LEAN passes custom data objects to the `OnData` method. For more information about custom data, see Custom Securities .

Security Types

LEAN uses the `SecurityType` enumeration as a synonym for asset classes. The `SecurityType` enumeration has the following members:

The `Base` type is for non-financial assets like custom and alternative data objects.

Securities

Properties

Introduction

`Security` objects contain the models and properties of an asset.

Security Properties

`Security` objects have the following properties:

Reality Models

`Security` objects contain references to the security level reality models . To customize the behavior of each security, configure its reality models.

Symbol Properties

The `SymbolProperties` property of a `Security` contains properties for a specific security. `SymbolProperties` objects have the following properties:

To create a `SymbolProperties` object, call the constructor.

```
symbol_properties = SymbolProperties(description, quoteCurrency, contractMultiplier,
minimumPriceVariation, lotSize, marketTicker)
```

PY

The following table describes the arguments of the `SymbolProperties` constructor:

Argument	Data Type	Description	Default Value
`description`	`string str`	The description of the security.	
`quoteCurrency`	`string str`	The quote currency of the security.	
`contractMultiplier`	`decimal float`	The contract multiplier for the security.	
`minimumPriceVariation`	`decimal float`	The minimum price variation (tick size) for the security.	
`lotSize`	`decimal float`	The lot size (lot size of the order) for the security.	
`marketTicker`	`string str`	The market ticker.	
`minimumOrderSize`	`decimal? float/NoneType`	The minimum order size allowed.	`None`
`priceMagnifier`	`decimal float`	This property allows normalizing live asset prices to US Dollars for Lean consumption. In some exchanges, for some securities, data is expressed in cents like corn Futures ('ZC').	1

Securities

Exchange

Introduction

The `Exchange` property of a `Security` object contains information about the exchange that lists the security.

Properties

The `Exchange` property of a `Security` object returns an `SecurityExchange` object, which has the following attributes:

Hours

To get the exchange hours, use the `Exchange.Hours` property on a `Security` object.

```
security_exchange_hours = self.Securities["SPY"].Exchange.Hours
```

The preceding code snippet returns a `SecurityExchangeHours` object, which has the following attributes:

To check if the exchange is open at a specific time, call the `IsOpen` method.

```
# Check if the exchange is open at a specific time
is_open_now = security_exchange_hours.IsOpen(self.Time, extendedMarketHours=False)

# Check if the exchange is open at any point in time over a specific interval
is_open = security_exchange_hours.IsOpen(self.Time, self.Time + timedelta(days=1),
extendedMarketHours=False)
```

To check if the exchange is open on a specific date, call the `IsDateOpen` method.

```
is_open = security_exchange_hours.IsDateOpen(self.Time)
```

To get the next market open time, call the `GetNextMarketOpen` method.

```
market_open_time = security_exchange_hours.GetNextMarketOpen(self.Time, extendedMarketHours=False)
```

To get the next market close time, call the `GetNextMarketClose` method.

```
market_close_time = security_exchange_hours.GetNextMarketClose(self.Time, extendedMarketHours=False)
```

To get the previous trading day, call the `GetPreviousTradingDay` method.

```
day = security_exchange_hours.GetPreviousTradingDay(self.Time)
```

To get the next trading day, call the `GetNextTradingDay` method.

```
day = security_exchange_hours.GetNextTradingDay(self.Time)
```

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
self.AddEquity("SPY", extendedMarketHours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

24 Hour Markets

The Crypto market trades 24/7, but other asset classes only trade during part of the week. Each market has an official trading schedule, but it can be impacted by daylight savings, holidays, and trading halts.

Securities

Requesting Data

Introduction

If you create a data subscription, your algorithm receives data updates for that security or custom data source.

Characteristics

We thoroughly vet datasets before we add them to the Data Market. The datasets in the Data Market are well-defined with robust ticker and `Symbol` links to ensure tickers are properly tracked through time. The datasets are consistently delivered on time and most of them are ready for live trading. All the datasets have at least one year of historical data and are free of survivorship bias.

Resolutions

Resolution is the duration of time that's used to sample a data source. The `Resolution` enumeration has the following members:

The default resolution for market data is `Minute` . To set the resolution for a security, pass the `resolution` argument when you create the security subscription.

```
self.AddEquity("SPY", Resolution.Daily)
```

PY

To set the resolution for all securities, set the `Resolution` universe setting before you create security subscriptions.

```
self.UniverseSettings.Resolution = Resolution.Daily
```

PY

To see which resolutions of data are available for a dataset, see the dataset listing in the Data Market . To create custom resolution periods, see Consolidating Data .

Data density describes the frequency of entries in a dataset. Datasets at the tick resolution have dense data density. All other resolutions usually have regular data density. If a non-tick resolution dataset doesn't have an entry at each sampling, it has sparse density.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.AddEquity("SPY", fillForward=False)
```

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
self.AddEquity("SPY", extendedMarketHours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

Remove Subscriptions

To remove a security subscription, call the `RemoveSecurity` method.

```
self.RemoveSecurity(self.symbol)
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings.

Markets

The datasets integrated into the Dataset Market cover many markets. The `Market` enumeration has the following members:

LEAN can usually determine the correct market based on the ticker you provide when you create the security subscription. To manually set the market for a security, pass a `market` argument when you create the security subscription.

```
self.AddEquity("SPY", market=Market.USA)
```

Quotas

There is no limit to the number of security subscriptions you can create, but some live data providers impose data subscription limits. To set a limit, in the `Initialize` method, set the `DataSubscriptionLimit` algorithm setting .

```
self.Settings.DataSubscriptionLimit = 500
```

All securities that you add to the algorithm count as one subscription, except Options and Futures. Every Option and Future contract counts as one subscription.

Securities

Handling Data

Introduction

LEAN packages the data for your subscriptions in a `Slice` object and passes it to the `OnData` method of your algorithm. To avoid look-ahead bias , LEAN only provides the data that's available at the current time in your algorithm. This processing style ensures that your algorithm backtests in the same manner that it trades live. Your algorithm uses the data to make trading decisions and LEAN uses the data to update your positions, track your portfolio value, and simulate orders.

Security Cache

To get the most recent data for a security, call the `GetLastData` method on the `Security` object.

```
PY
data = self.Securities["SPY"].GetLastData()
```

Timeslice

The `Slice` that LEAN passes to the `OnData` method represents all of the data for your subscriptions at a single point in time. The `Slice` object contains data like `Tick` objects, `TradeBar` objects, `QuoteBar` objects, corporate actions , and chains for Option and Future contracts. You can use the data in the `Slice` to make trading decisions.

To access data in the `Slice` , index it with the security `Symbol` . If you use the security ticker instead of the `Symbol` , LEAN automatically finds the `Symbol` .

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.symbol):
        my_data = slice[self.symbol]
```

The following table shows the `Slice` property to index based on the data format you want:

Data Format	Slice Property
`TradeBar`	`Bars`
`QuoteBar`	`QuoteBars`
`Tick`	`Ticks`

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.symbol):
        bar = slice.Bars[self.symbol]
```

If you just index the `Slice` instead of the preceding properties, it returns the correct object. If your data subscription provides `QuoteBar` objects and you index the `Slice` with the security `Symbol` , it returns the `QuoteBar` .

`Slice` objects have the following properties:

For more information about the `Slice` class, see Timeslices .

Securities

Filtering Data

Introduction

Unfiltered raw data can be faulty for a number of reasons, including invalid data entry. Moreover, high-frequency traders can deploy bait-and-switch strategies by submitting bait orders to deceive other market participants, making raw data noisy and untradeable. To avoid messing up with our trading logic and model training, you can filter out suspicious raw data with a data filter.

Set Models

To set a data filter for a security, call the `SetDataFilter` property on the `Security` object.

```py
# In Initialize
spy = AddEquity("SPY")
spy.SetDataFilter(SecurityDataFilter())
```

You can also set the data filter model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `SetSecurityInitializer` before you create the subscriptions.

```py
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetDataFilter(SecurityDataFilter())
```

Default Behavior

The following table shows the default data filter for each security type:

Security Type	Default Filter
`Equity`	EquityDataFilter
`Option`	OptionDataFilter
`Forex`	ForexDataFilter
`Index`	IndexDataFilter
`Cfd`	CfdDataFilter
Others	SecurityDataFilter

None of the preceding filters filter out any data.

Model Structure

Data filtering models must implement a `Filter` method, which receives `Security` and `BaseData` objects and then returns a `boolean` object that represents if the data point should be filtered out.

```
class MyDataFilter:
    def Filter(self, vehicle: Security, data: BaseData) -> bool:
        return True
```

US Equity

Requesting Data

Introduction

Request US Equity data in your algorithm to receive a feed of asset prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Equities dataset listing . To trade US Equities live, you can use our US Equities data feed or one of the brokerage data feeds .

Create Subscriptions

To create an Equity subscription, in the `Initialize` method, call the `AddEquity` method. The `AddEquity` method returns an `Equity` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
self.symbol = self.AddEquity("SPY").Symbol
```

The `AddEquity` method creates a subscription for a single Equity asset and adds it to your **user-defined** universe. To create a dynamic universe of Equities, add an Equity universe or an Equity Universe Selection model .

To view the supported assets in the US Equities dataset, see the Data Explorer .

Resolutions

The following table shows the available resolutions and data formats for Equity subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	✓
`Second`	✓	✓		
`Minute`	✓	✓		
`Hour`	✓			
`Daily`	✓			

The default resolution for Equity subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddEquity` method.

```
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

To create custom resolution periods, see Consolidating Data .

Asset Primary Exchange

When a stock like Apple is listed, it's listed on Nasdaq. The open auction tick on Nasdaq is the price that's used as the official open of the day. NYSE, BATS, and other exchanges also have opening auctions, but the only official opening price for Apple is the opening auction on the exchange where it was listed.

Supported Markets

LEAN groups all of the US Equity exchanges under `Market.USA` . In live mode, the brokerage routes the orders to the exchange that provides the best price.

To set the market for a security, pass a `market` argument to the `AddEquity` method.

```
self.symbol = self.AddEquity("SPY", market=Market.USA).Symbol
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.AddEquity("SPY", fillForward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. In backtests, the default leverage for margin accounts is 2x leverage and leverage is not available for cash accounts. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `AddEquity` method.

```
self.symbol = self.AddEquity("SPY", leverage=3).Symbol
```

In live trading, the brokerage determines how much leverage you may use. For more information about the leverage they provide, see Brokerages .

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
self.AddEquity("SPY", extendedMarketHours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If

you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Data Normalization

The data normalization mode defines how historical data is adjusted for corporate actions . The data normalization mode affects the data that LEAN passes to `OnData` and the data from history requests . By default, LEAN adjusts US Equity data for splits and dividends to produce a smooth price curve, but the following data normalization modes are available:

We use the entire split and dividend history to adjust historical prices. This process ensures you get the same adjusted prices, regardless of the backtest end date.

To set the data normalization mode for a security, pass a `dataNormalizationMode` argument to the `AddEquity` method.

```
self.symbol = self.AddEquity("SPY", dataNormalizationMode=DataNormalizationMode.Raw).Symbol
```

PY

Properties

The `AddEquity` method returns an `Equity` object, which have the following properties:

US Equity

Handling Data

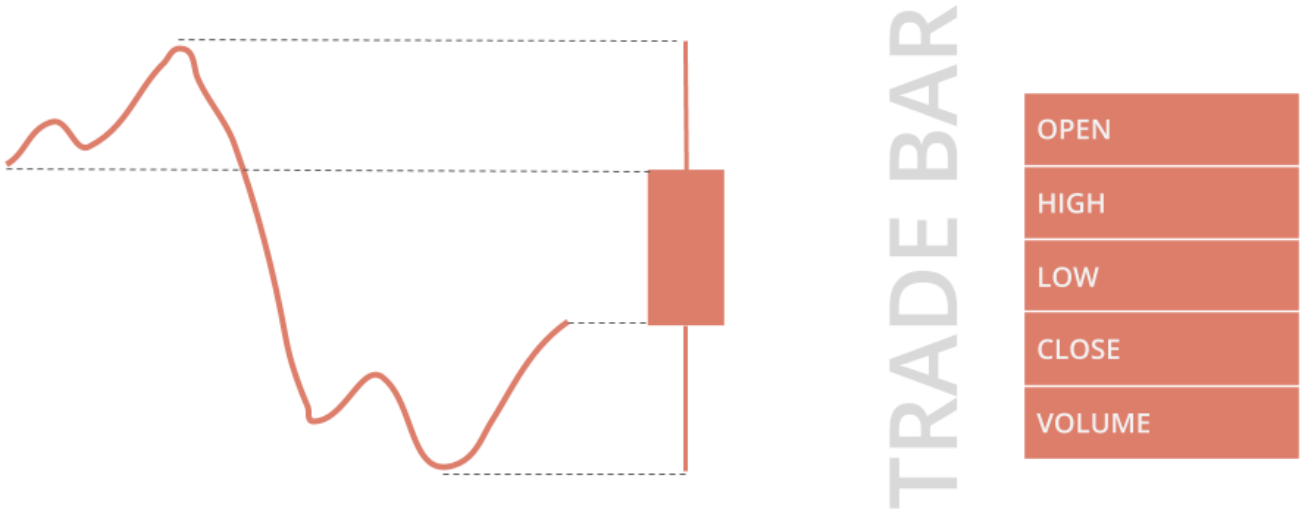
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `Symbol` , but we recommend you use the `Symbol` .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the security `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
```

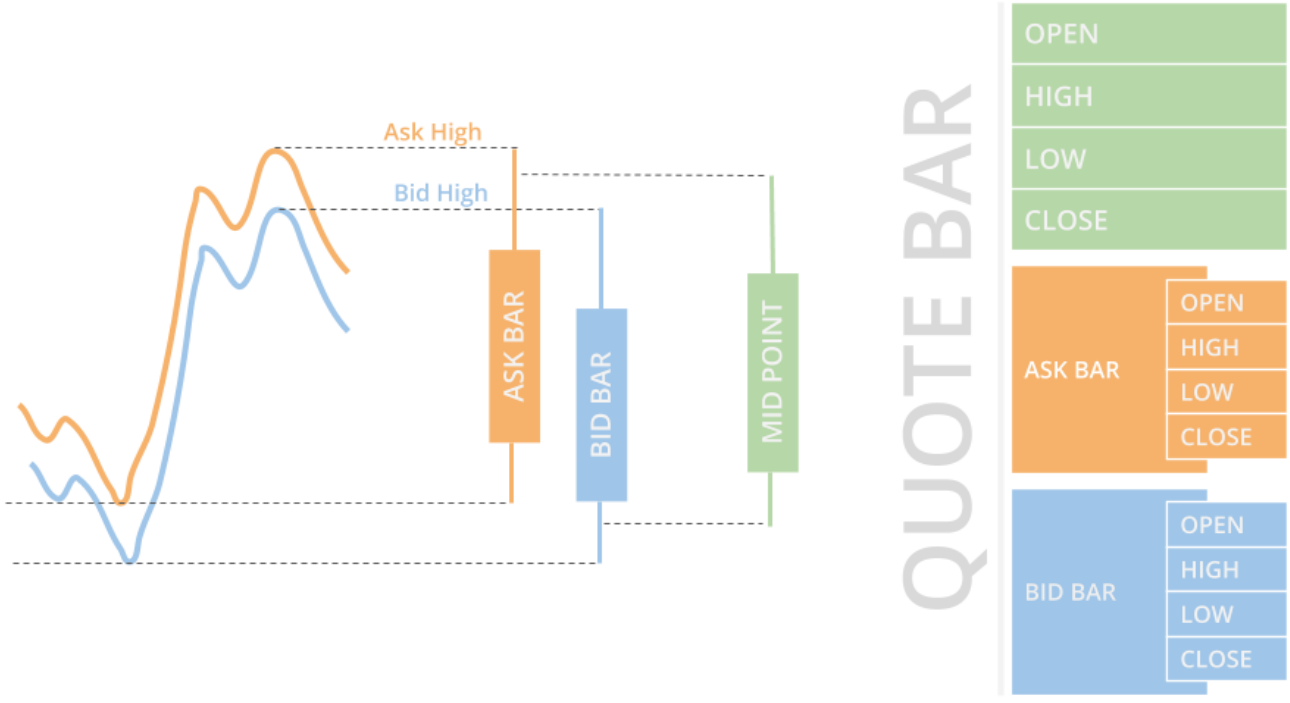
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        close_price = trade_bar.Close
```

We adjust the daily open and close price of bars to reflect the official auction prices .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the security `Symbol` . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price. `Tick` objects have the following properties:

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            price = tick.Price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            price = tick.Price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able

to perform your own online tick filtering.

If we detect a tick that may be suspicious , we set its `Suspicious` flag to true.

Other Data Formats

For more information about data formats available for US Equities, see Corporate Actions .

US Equity

Corporate Actions

Introduction

US Equity subscriptions provide notifications for splits, dividends, symbol changes, and delistings.

Splits

When a company does a stock split, the number of shares each shareholder owns increases and the price of each share decreases. When a company does a reverse stock split, the number of shares each shareholder owns decreases and the price of each share increases. A company may perform a stock split or a reverse stock split to adjust the price of their stock so that more investors trade it and the liquidity increases.

When a stock split or reverse stock split occurs for an Equity in your algorithm, LEAN sends a `Split` object to the `OnData` method. Split objects have the following properties:

You receive `Split` objects when a split is in the near future and when it occurs. To know if the split occurs in the near future or now, check the `Type` property.

If you backtest without the `Raw` data normalization mode , the splits are factored into the price and volume. If you backtest with the `Raw` data normalization mode or trade live, when a split occurs, LEAN automatically adjusts your positions based on the `SplitFactor` . If the post-split quantity isn't a valid lot size , LEAN credits the remaining value to your cashbook in your account currency. If you have indicators in your algorithm, reset your indicators when splits occur so that the data in your indicators account for the price adjustments that the splits cause.

To get the `Split` objects in the `Slice` , index the `Splits` property of the `Slice` with the security `Symbol` . The `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Splits` property contains data for your security before you index it with the security `Symbol` .

```
PY
def OnData(self, slice: Slice) -> None:
    split = slice.Splits.get(self.symbol)
    if split:
        pass
```

You can also iterate through the `Splits` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Split` objects.

```
PY
def OnData(self, slice: Slice) -> None:
    for symbol, split in slice.Splits.items():
        pass
```

LEAN stores the data for stock splits in factor files. To view some example factor files, see the LEAN GitHub repository . In backtests, your algorithm receives `Split` objects at midnight. In live trading, your algorithm receives `Split` objects

when the factor files are ready.

If you hold an Option contract for an underlying Equity when a split occurs, LEAN closes your Option contract position.

If a split event occurs before your order is filled, the unfilled portion of the order is adjusted automatically, where its quantity is multiplied by the split factor and the limit/stop/trigger price (if any) is divided by the split factor.

Dividends

A dividend is a payment that a company gives to shareholders to distribute profits. When a dividend payment occurs for an Equity in your algorithm, LEAN sends a `Dividend` object to the `OnData` method. `Dividend` objects have the following properties:

If you backtest with the `Adjusted` or `TotalReturn` data normalization mode, the dividends are factored into the price. If you backtest with the other data normalization modes or trade live, when a dividend payment occurs, LEAN automatically adds the payment amount to your cashbook. If you have indicators in your algorithm, reset your indicators when dividend payments occur so that the data in your indicators account for the price adjustments that the dividend causes.

To get the `Dividend` objects in the `Slice` , index the `Dividends` property of the `Slice` with the security `Symbol` . The `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Dividends` property contains data for your security before you index it with the security `Symbol` .

```
PY
def OnData(self, slice: Slice) -> None:
    dividend = slice.Dividends.get(self.symbol)
    if dividend:
        pass
```

You can also iterate through the `Dividends` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Dividend` objects.

```
PY
def OnData(self, slice: Slice) -> None:
    for symbol, dividend in slice.Dividends.items():
        pass
```

For a full example, see the DividendAlgorithm in the LEAN GitHub repository.

Symbol Changes

The benefit of the `Symbol` class is that it always maps to the same security, regardless of their trading ticker. When a company changes its trading ticker, LEAN sends a `SymbolChangedEvent` to the `OnData` method. `SymbolChangedEvent` objects have the following properties:

To get the `SymbolChangedEvent` objects in the `Slice` , index the `SymbolChangedEvents` property of the `Slice` with the security `Symbol` . The `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `SymbolChangedEvents` property contains data for your security before you index it with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    symbol_changed_event = slice.SymbolChangedEvents.get(self.symbol)
    if symbol_changed_event:
        pass
```

You can also iterate through the `SymbolChangedEvents` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `SymbolChangedEvent` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, symbol_changed_event in slice.SymbolChangedEvents.items():
        pass
```

If you have an open order for a security when they change their ticker, LEAN cancels your order. To keep your order, in the `OnOrderEvent` method, get the quantity and `Symbol` of the cancelled order and submit a new order.

```
def OnOrderEvent(self, order_event: OrderEvent) -> None:
    if order_event.Status == OrderStatus.Canceled:
        ticket = self.Transactions.GetOrderTicket(order_event.OrderId)
        if "symbol changed event" in ticket.Tag:
            self.Transactions.AddOrder(ticket.SubmitRequest)
```

LEAN stores the data for ticker changes in map files. To view some example map files, see the LEAN GitHub repository .

Delistings

When a company is delisting from an exchange, LEAN sends a `Delisting` object to the `OnData` method. `Delisting` objects have the following properties:

You receive `Delisting` objects when a delisting is in the near future and when it occurs. To know if the delisting occurs in the near future or now, check the `Type` property.

To get the `Delisting` objects in the `Slice` , index the `Delistings` property of the `Slice` with the security `Symbol` . The `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Delistings` property contains data for your security before you index it with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    delisting = slice.Delistings.get(self.symbol)
    if delisting:
        pass
```

You can also iterate through the `Delistings` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Delisting` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, delisting in slice.Delistings.items():
        pass
```

The delist warning occurs on the final trading day of the stock to give you time to gracefully exit out of positions before LEAN automatically liquidates them.

```py
if delisting.Type == DelistingType.Warning:
    # Liquidate with MarketOnOpenOrder on delisting warning
    quantity = self.Portfolio[symbol].Quantity
    if quantity != 0:
        self.MarketOnOpenOrder(symbol, -quantity)
```

For a full example, see the DelistingEventsAlgorithm in the LEAN GitHub repository.

US Equity

Corporate Fundamentals

Introduction

Corporate fundamental data contains all the information on the underlying company of an Equity asset and the information in their financial statements. Since corporate data contains information not found in price and alternative data, adding corporate data to your trading strategies provides you with more information so you can make more informed trading decisions. Corporate fundamental data is available through the US Fundamental Data from Morningstar . To get fundamental data into your algorithm, add a fundamental universe .

Properties

To get fundamental data, access the `FineFundamental` properties in your fine universe selection function or access the `Fundamentals` property of the `Equity` objects in your fundamental universe.

```
PY
fundamentals = self.Securities[self.symbol].Fundamentals
```

The US Fundamentals dataset provides FineFundamental objects. To filter FineFundamental objects, you can use the MorningstarSectorCode, MorningstarIndustryGroupCode, and MorningstarIndustryCode enumeration values.

FineFundamental Attributes

FineFundamental objects have the following attributes:

MorningstarSectorCode Enumeration

Sectors are large super categories of data. To access the sector of an Equity, use the **MorningstarSectorCode** property.

```
PY
filtered_fine = [x for x in fine if x.AssetClassification.MorningstarSectorCode ==
MorningstarSectorCode.Technology]
```

The **MorningstarSectorCode** enumeration has the following members:

MorningstarIndustryGroupCode Enumeration

Industry groups are clusters of related industries which tie together. To access the industry group of an Equity, use the **MorningstarIndustryGroupCode** property.

```
PY
filtered_fine = [x for x in fine if x.AssetClassification.MorningstarIndustryGroupCode ==
MorningstarIndustryGroupCode.ApplicationSoftware]
```

The **MorningstarIndustryGroupCode** enumeration has the following members:

MorningstarIndustryCode Enumeration

Industries are the finest level of classification available and are the individual industries according to the Morningstar classification system. To access the industry group of an Equity, use the **MorningstarIndustryCode** property:

```
PY
filtered_fine = [x for x in fine if x.AssetClassification.MorningstarIndustryCode ==
MorningstarIndustryCode.SoftwareApplication]
```

The **MorningstarIndustryCode** enumeration has the following members:

Exchange Id Values

Exchange Id is mapped to represent the exchange that lists the Equity. To access the exchange Id of an Equity, use the **PrimaryExchangeID** property.

```
PY
filtered_fine = [x for x in fine if x.CompanyReference.PrimaryExchangeID == "NAS"]
```

The exchanges are represented by the following string values:

String Representation	Exchange
NYS	New York Stock Exchange (NYSE)
NAS	NASDAQ
ASE	American Stock Exchange (AMEX)
TSE	Tokyo Stock Exchange
AMS	Amsterdam Internet Exchange
SGO	Santiago Stock Exchange
XMAD	Madrid Stock Exchange
ASX	Australian Securities Exchange
BVMF	B3 (stock exchange)
LON	London Stock Exchange
TKS	Istanbul Stock Exchange Settlement and Custody Bank
SHG	Shanghai Exchange
LIM	Lima Stock Exchange

String Representation	Exchange
FRA	Frankfurt Stock Exchange
JSE	Johannesburg Stock Exchange
MIL	Milan Stock Exchange
TAE	Tel Aviv Stock Exchange
STO	Stockholm Stock Exchange
ETR	Deutsche Boerse Xetra Core
PAR	Paris Stock Exchange
BUE	Buenos Aires Stock Exchange
KRX	Korea Exchange
SWX	SIX Swiss Exchange
PINX	Pink Sheets (OTC)
CSE	Canadian Securities Exchange
PHS	Philippine Stock Exchange
MEX	Mexican Stock Exchange
TAI	Taiwan Stock Exchange
IDX	Indonesia Stock Exchange
OSL	Oslo Stock Exchange
BOG	Colombia Stock Exchange
NSE	National Stock Exchange of India
HEL	Nasdaq Helsinki
MISX	Moscow Exchange
HKG	Hong Kong Stock Exchange

BRU	Brussels Stock Exchange

String Representation	Exchange
BATS	BATS Global Markets
ARCX	NYSE Arca
GREY	Grey Market (OTC)
DUS	Dusseldorf Stock Exchange
BER	Berlin Stock Exchange
ROCO	Taipei Exchange
CNQ	Canadian Trading and Quotation System Inc.
BSP	Bangko Sentral ng Pilipinas
NEOE	NEO Exchange

Historical Data

To get historical fundamental data, set a warm-up period and save the fundamental data during the warm-up period. It's not currently possible to make a history request for fundamental data in an algorithm. Subscribe to GitHub Issue #4890 to track the feature progress.

Data Updates

The US Fundmamental dataset only provides the originally-reported figures. If there was a mistake in reporting a figure, the data value isn't fixed later. In live trading, new fundamental data is available to your algorithms at approximately 6 AM Eastern Time (ET) each day. The majority of the corporate data update occurs once per month, but the financial ratios update daily. If there is no new data for a period of time, the previous data is filled forward.

US Equity

Shorting

Introduction

In a regular long position, you buy shares and then sell them later to close the trade. In a short position, you borrow shares, sell them, and then buy the shares back later to close the trade. Short positions let you profit when a security's price decreases while you have the position open, but there are risks involved. For example, you can get a margin call and you may incur borrowing costs.

Holdings Accounting

If you have an open long position, your portfolio has a positive quantity of shares for that security. In contrast, if you have an open short position, your portfolio has a negative quantity of shares for that security.

Borrowing Costs

In live trading, you usually pay a fee to borrow shares that you use to open a short position. Part of the fee goes to the investor that provided you with the opportunity to short with their shares. The borrowing rate is set by your live brokerage. In backtests, LEAN doesn't currently model borrowing costs, but we have an open GitHub Issue to add the functionality. Subscribe to GitHub Issue #4563 to track the feature progress.

US Equity

Data Preparation

Introduction

The US Equities dataset provides price data for backtests and live trading.

Sourcing

The US Equities data feed consolidates market data across all of the exchanges. Over-the-Counter (OTC) trades are excluded. The data feed is powered by the Securities Information Processor (SIP), so it has 100% market coverage. In contrast, free platforms that display data feeds like the Better Alternative Trading System (BATS) only have about 6-7% market coverage .

We provide live splits, dividends, and corporate actions for US companies. We deliver them to your algorithm before the trading day starts.

Bar Building

We aggregate ticks to build bars.

The bar-building process can exclude ticks. If a tick is excluded, its volume is aggregated in the bar but its price is not aggregated in the bar. Ticks are excluded if any of the following statements are true:

- The tick is suspicious.
- The tick is from the FINRA exchange and meets our price and volume thresholds.
- The trade has none of the following included `TradeConditionFlags` and at least one of the following excluded `TradeConditionFlags` :

`TradeConditionFlags`	**Status**	**Description**
`Regular`	Included	A trade made without stated conditions is deemed the regular way for settlement on the third business day following the transaction date.
`FormT`	Included	Trading in extended hours enables investors to react quickly to events that typically occur outside regular market hours, such as earnings reports. However, liquidity may be constrained during such Form T trading, resulting in wide bid-ask spreads.
`Cash`	Included	A transaction that requires delivery of securities and payment on the same day the trade takes place.

TradeConditionFlags	Status	Description
ExtendedHours	Included	Identifies a trade that was executed outside of regular primary market hours and is reported as an extended hours trade.
NextDay	Included	A transaction that requires the delivery of securities on the first business day following the trade date.
OfficialClose	Included	Indicates the "official" closing value determined by a Market Center. This transaction report will contain the market center generated closing price.
OfficialOpen	Included	Indicates the 'Official' open value as determined by a Market Center. This transaction report will contain the market center generated opening price.
ClosingPrints	Included	The transaction that constituted the trade-through was a single priced closing transaction by the Market Center.
OpeningPrints	Included	The trade that constituted the trade-through was a single priced opening transaction by the Market Center.
IntermarketSweep	Excluded	The transaction that constituted the trade-through was the execution of an order identified as an Intermarket Sweep Order.
TradeThroughExempt	Excluded	Denotes whether or not a trade is exempt (Rule 611).
OddLot	Excluded	Denotes the trade is an odd lot less than a 100 shares.

- The quote has a size of less than 100 shares.
- The quote has one of the following `QuoteConditionFlags` :

QuoteConditionFlags	Description
Closing	Indicates that this quote was the last quote for a security for that Participant.
NewsDissemination	Denotes a regulatory trading halt when relevant news influencing the security is being disseminated. Trading is suspended until the primary market determines that an adequate publication or disclosure of information has occurred.
NewsPending	Denotes a regulatory Trading Halt due to an expected news announcement, which may influence the security. An Opening Delay or Trading Halt may be continued once the news has been disseminated.
TradingRangeIndication	Denotes the probable trading range (Bid and Offer prices, no sizes) of a security that is not Opening Delayed or Trading Halted. The Trading Range Indication is used prior to or after the opening of a security.
OrderImbalance	Denotes a non-regulatory halt condition where there is a significant imbalance of buy or sell orders.
Resume	Indicates that trading for a Participant is no longer suspended in a security that had been Opening Delayed or Trading Halted.

- The quote has none of the following `QuoteConditionFlags` :

QuoteConditionFlags	Description
Regular	This condition is used for the majority of quotes to indicate a normal trading environment.
Slow	This condition is used to indicate that the quote is a Slow Quote on both the bid and offer sides due to a Set Slow List that includes high price securities.
Gap	While in this mode, auto-execution is not eligible, the quote is then considered manual and non-firm in the bid and offer, and either or both sides can be traded through as per Regulation NMS.
OpeningQuote	This condition can be disseminated to indicate that this quote was the opening quote for a security for that Participant.
FastTrading	For extremely active periods of short duration. While in this mode, the UTP Participant will enter quotations on a best efforts basis.
Resume	Indicate that trading for a Participant is no longer suspended in a security which had been Opening Delayed or Trading Halted.

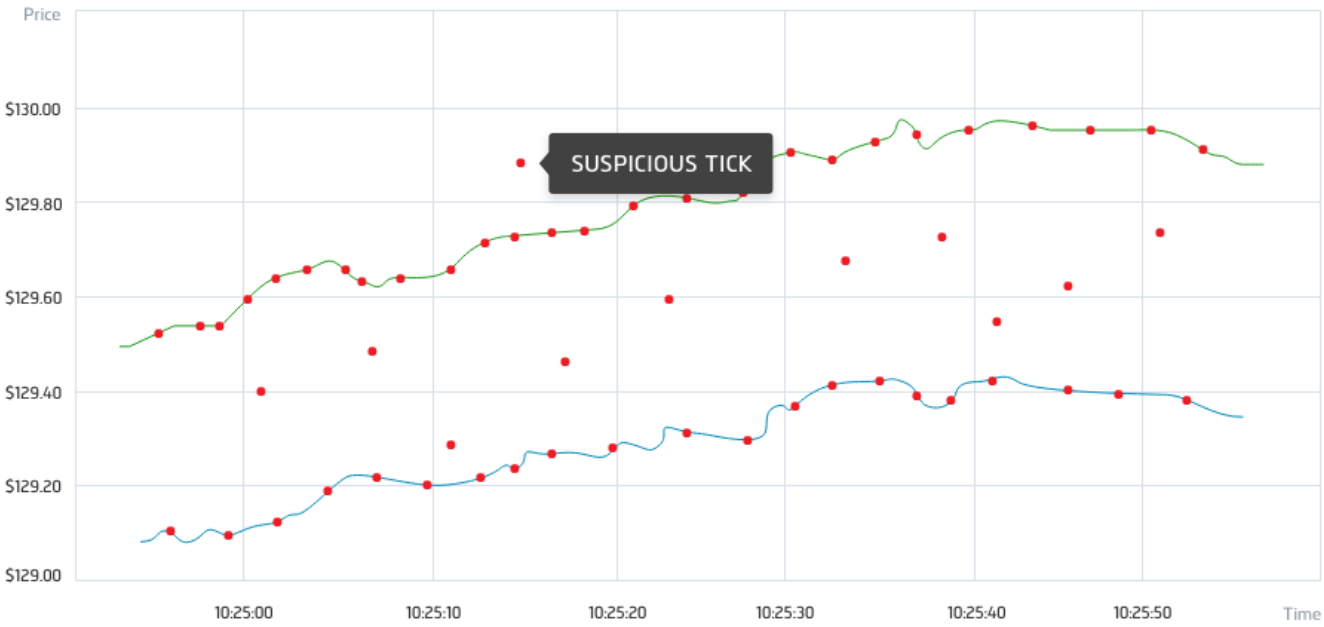
In the preceding tables, **Participant** refers to the entities on page 19 of the Consolidated Tape System Multicast Output Binary Specification .

Suspicious Ticks

Tick price data is raw and unfiltered, so it can contain a lot of noise. If a tick is not tradable, we flag it as suspicious. This process makes the bars a more realistic representation of what you could execute in live trading. If you use tick data, avoid using suspicious ticks in your algorithms as informative data points. We recommend only using tick data if you understand the risks and are able to perform your own tick filtering. Ticks are flagged as suspicious in the following

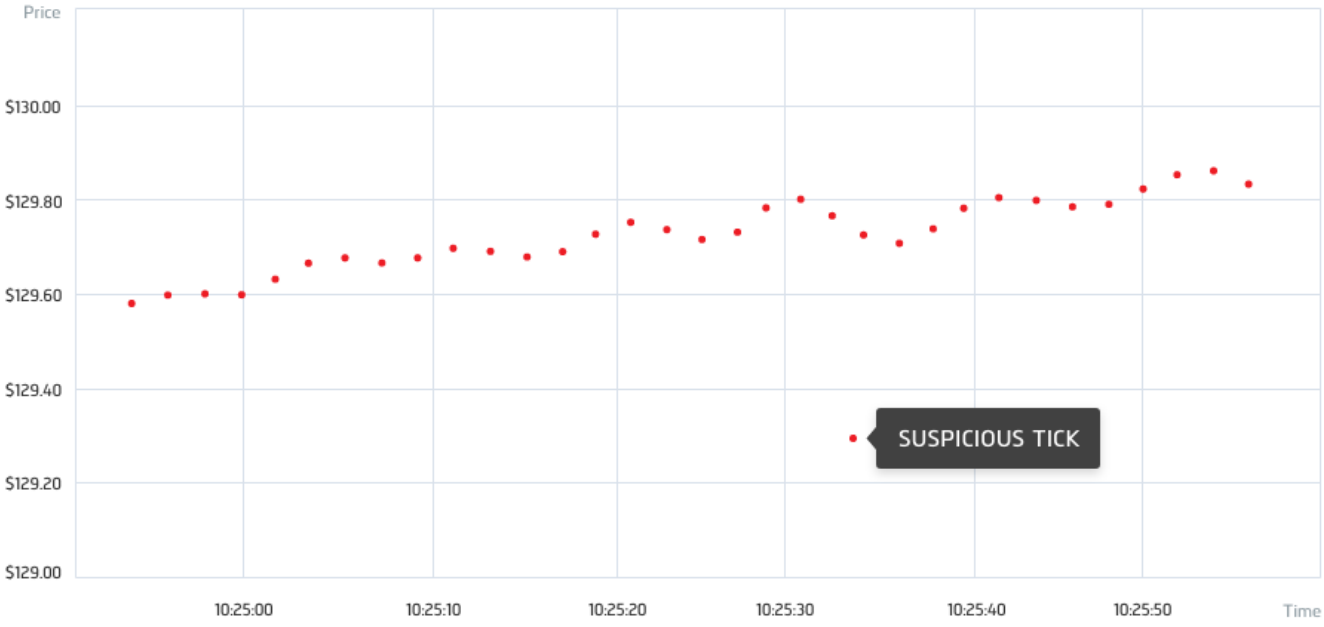
situations:

- The tick occurs below the best bid or above the best ask



This image shows a tick that occurred above the best ask price of a security. The green line represents the best ask of the security, the blue line represents the best bid of the security, and the red dots represent trade ticks. The ticks between the best bid and ask occur from filling hidden orders. The tick that occurred above the best ask price is flagged as suspicious.

- The tick occurs far from the current market price



This image shows a tick that occurred far from the price of the security. The red dots represent trade ticks. The tick that occurred far from the market price is flagged as suspicious.

- The tick occurs on a dark pool
- The tick is rolled back

- The tick is reported late

Market Auction Prices

The opening and closing price of the day is set by very specific opening and closing auction ticks. When a stock like Apple is listed, it's listed on Nasdaq. The open auction tick on Nasdaq is the price that's used as the official open of the day. NYSE, BATS, and other exchanges also have opening auctions, but the only official opening price for Apple is the opening auction on the exchange where it was listed.

We set the opening and closing prices of the first and last bars of the day to the official auction prices. This process is used for second, minute, hour, and daily bars for the 9:30 AM and 4:30 PM Eastern Time (ET) prices. In contrast, other platforms might not be using the correct opening and closing prices.

The official auction prices are usually emitted 2-30 seconds after the market open and close. We do our best to use the official opening and closing prices in the bars we build, but the delay can be so large that there isn't enough time to update the opening and closing price of the bar before it's injected into your algorithms. For example, if you subscribe to second resolution data, we wait until the end of the second for the opening price but most second resolution data won't get the official opening price. If you subscribe to minute resolution data, we wait until the end of the minute for the opening auction price. Most of the time, you'll get the actual opening auction price with minute resolution data, but there are always exceptions. Nasdaq and NYSE can have delays in publishing the opening auction price, but we don't have control over those issues and we have to emit the data on time so that you get the bar you are expecting.

Live and Backtesting Differences

In live trading, bars are built using the exchange timestamps with microsecond accuracy. This microsecond-by-microsecond processing of the ticks can mean that the individual bars between live trading and backtesting can have slightly different ticks. As a result, it's possible for a tick to be counted in different bars between backtesting and live trading, which can lead to bars having slightly different open, high, low, close, and volume values.

Data Availability

In live trading, live data is available in real-time. In backtests, live data is available at the following pre-market trading session.

US Equity

Market Hours

Introduction

This page shows the trading hours, holidays, and time zone of the US Equity market.

Pre-market Hours

The following table shows the pre-market hours for the US Equity market:

Weekday	Time (America/New York)
Monday	04:00:00 to 09:30:00
Tuesday	04:00:00 to 09:30:00
Wednesday	04:00:00 to 09:30:00
Thursday	04:00:00 to 09:30:00
Friday	04:00:00 to 09:30:00

Regular Trading Hours

The following table shows the regular trading hours for the US Equity market:

Weekday	Time (America/New York)
Monday	09:30:00 to 16:00:00
Tuesday	09:30:00 to 16:00:00
Wednesday	09:30:00 to 16:00:00
Thursday	09:30:00 to 16:00:00
Friday	09:30:00 to 16:00:00

Post-market Hours

The following table shows the post-market hours for the US Equity market:

Weekday	Time (America/New York)
Monday	16:00:00 to 20:00:00
Tuesday	16:00:00 to 20:00:00
Wednesday	16:00:00 to 20:00:00
Thursday	16:00:00 to 20:00:00
Friday	16:00:00 to 20:00:00

Holidays

LEAN uses the trading holidays from the NYSE website.

The following table shows the dates of holidays for the US Equity market:

Date (*yyyy-mm-dd*)				
1998-01-01	1998-01-19	1998-02-16	1998-04-10	1998-05-25
1998-07-03	1998-09-07	1998-11-26	1998-12-25	1999-01-01

Late Opens

There are no days with late opens.

Time Zone

The US Equity market trades in the `America/New York` time zone.

Asset Classes

India Equity

India Equities represent partial ownership in an Indian corporation.

India Equity

Requesting Data

Introduction

Request India Equity data in your algorithm to receive a feed of asset prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the India Equities dataset listing . To trade India Equities live, you can use one of the brokerage data feeds .

Create Subscriptions

To create an India Equity subscription, in the `Initialize` method, call the `AddEquity` method. The `AddEquity` method returns an `Equity` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
PY
self.symbol = self.AddEquity("YESBANK", market=Market.India).Symbol
```

If you set the brokerage model to an India brokerage, you don't need to pass a `market` argument. To view the integrated brokerages that offer India Equities, see Brokerages .

To view the supported assets in the India Equities dataset, see the Data Explorer .

Resolutions

The following table shows the available resolutions and data formats for India Equity subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				
`Second`				
`Minute`	✓			
`Hour`	✓			
`Daily`	✓			

The default resolution for India Equity subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddEquity` method.

```
PY
self.symbol = self.AddEquity("YESBANK", Resolution.Daily, Market.India).Symbol
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

LEAN groups all of the India Equity exchanges under `Market.India` . To set the market for a security, pass a `market` argument to the `AddEquity` method.

```
self.symbol = self.AddEquity("YESBANK", market=Market.India).Symbol
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.symbol = self.AddEquity("YESBANK", market=Market.India, fillForward=False).Symbol
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The amount of margin that's available depends on the brokerage model you use. For more information about the margin requirements of each brokerage, see the **Margin** section of the brokerage guides . To change the amount of leverage you can use for a security, pass a `leverage` argument to the `AddEquity` method.

```
self.symbol = self.AddEquity("YESBANK", market=Market.India, leverage=3).Symbol
```

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
self.symbol = self.AddEquity("YESBANK", market=Market.India, extendedMarketHours=True).Symbol
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Data Normalization

The data normalization mode defines how historical data is adjusted for corporate actions . The data normalization mode affects the data that LEAN passes to `OnData` and the data from history request . By default, LEAN adjusts India Equity data for splits and dividends to produce a smooth price curve. The following data normalization modes are

available:

We use the entire split and dividend history to adjust historical prices. This process ensures you get the same adjusted prices, regardless of the backtest end date.

To set the data normalization mode for a security, pass a `dataNormalizationMode` argument to the `AddEquity` method..

```
self.symbol = AddEquity("YESBANK", market=Market.India,
dataNormalizationMode=DataNormalizationMode.Raw).Symbol
```

PY

Properties

The `AddEquity` method returns an `Equity` object, which have the following properties:

India Equity

Handling Data

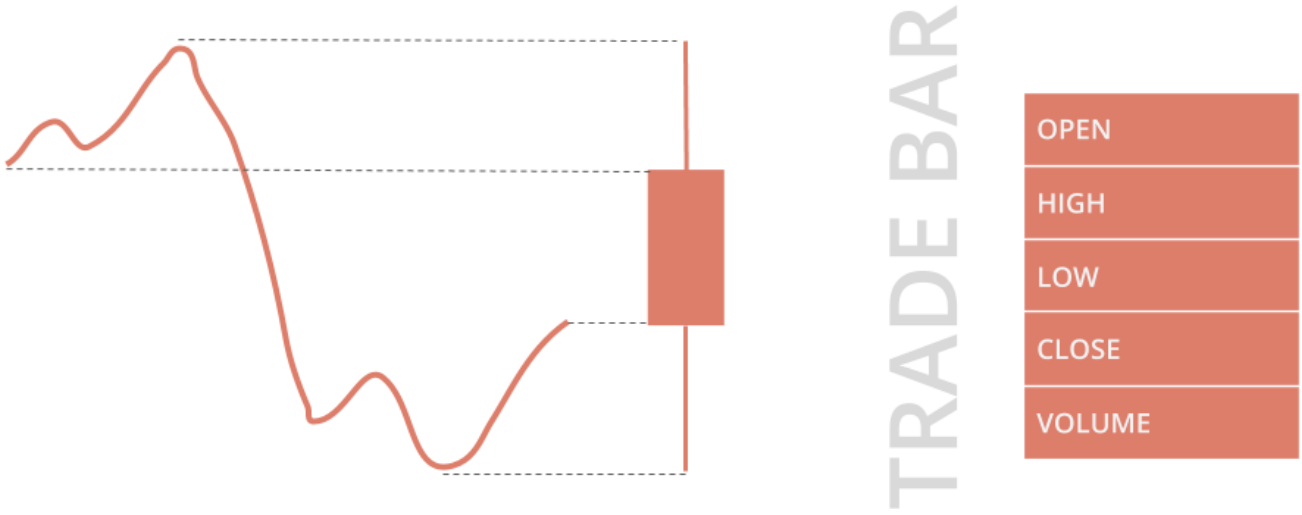
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `Symbol` , but we recommend you use the `Symbol` .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the security `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        close_price = trade_bar.Close
```

India Equity

Corporate Actions

Introduction

India Equity subscriptions provide notifications for splits, dividends, symbol changes, and delistings.

Splits

When a company does a stock split, the number of shares each shareholder owns increases and the price of each share decreases. When a company does a reverse stock split, the number of shares each shareholder owns decreases and the price of each share increases. A company may perform a stock split or a reverse stock split to adjust the price of their stock so that more investors trade it and the liquidity increases.

When a stock split or reverse stock split occurs for an Equity in your algorithm, LEAN sends a `Split` object to the `OnData` method. Split objects have the following properties:

You receive `Split` objects when a split is in the near future and when it occurs. To know if the split occurs in the near future or now, check the `Type` property.

If you backtest without the `Raw` data normalization mode , the splits are factored into the price and volume. If you backtest with the `Raw` data normalization mode or trade live, when a split occurs, LEAN automatically adjusts your positions based on the `SplitFactor` . If the post-split quantity isn't a valid lot size , LEAN credits the remaining value to your cashbook in your account currency. If you have indicators in your algorithm, reset your indicators when splits occur so that the data in your indicators account for the price adjustments that the splits cause.

To get the `Split` objects in the `Slice` , index the `Splits` property of the `Slice` with the security `Symbol` . The `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Splits` property contains data for your security before you index it with the security `Symbol` .

```
PY
def OnData(self, slice: Slice) -> None:
    split = slice.Splits.get(self.symbol)
    if split:
        pass
```

You can also iterate through the `Splits` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Split` objects.

```
PY
def OnData(self, slice: Slice) -> None:
    for symbol, split in slice.Splits.items():
        pass
```

LEAN stores the data for stock splits in factor files. To view some example factor files, see the LEAN GitHub repository . In backtests, your algorithm receives `Split` objects at midnight. In live trading, your algorithm receives `Split` objects

when the factor files are ready.

If you hold an Option contract for an underlying Equity when a split occurs, LEAN closes your Option contract position.

If a split event occurs before your order is filled, the unfilled portion of the order is adjusted automatically, where its quantity is multiplied by the split factor and the limit/stop/trigger price (if any) is divided by the split factor.

Dividends

A dividend is a payment that a company gives to shareholders to distribute profits. When a dividend payment occurs for an Equity in your algorithm, LEAN sends a `Dividend` object to the `OnData` method. `Dividend` objects have the following properties:

If you backtest with the `Adjusted` or `TotalReturn` data normalization mode, the dividends are factored into the price. If you backtest with the other data normalization modes or trade live, when a dividend payment occurs, LEAN automatically adds the payment amount to your cashbook. If you have indicators in your algorithm, reset your indicators when dividend payments occur so that the data in your indicators account for the price adjustments that the dividend causes.

To get the `Dividend` objects in the `Slice` , index the `Dividends` property of the `Slice` with the security `Symbol` . The `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Dividends` property contains data for your security before you index it with the security `Symbol` .

```
PY
def OnData(self, slice: Slice) -> None:
    dividend = slice.Dividends.get(self.symbol)
    if dividend:
        pass
```

You can also iterate through the `Dividends` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Dividend` objects.

```
PY
def OnData(self, slice: Slice) -> None:
    for symbol, dividend in slice.Dividends.items():
        pass
```

For a full example, see the DividendAlgorithm in the LEAN GitHub repository.

Symbol Changes

The benefit of the `Symbol` class is that it always maps to the same security, regardless of their trading ticker. When a company changes its trading ticker, LEAN sends a `SymbolChangedEvent` to the `OnData` method. `SymbolChangedEvent` objects have the following properties:

To get the `SymbolChangedEvent` objects in the `Slice` , index the `SymbolChangedEvents` property of the `Slice` with the security `Symbol` . The `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `SymbolChangedEvents` property contains data for your security before you index it with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    symbol_changed_event = slice.SymbolChangedEvents.get(self.symbol)
    if symbol_changed_event:
        pass
```

You can also iterate through the `SymbolChangedEvents` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `SymbolChangedEvent` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, symbol_changed_event in slice.SymbolChangedEvents.items():
        pass
```

If you have an open order for a security when they change their ticker, LEAN cancels your order. To keep your order, in the `OnOrderEvent` method, get the quantity and `Symbol` of the cancelled order and submit a new order.

```
def OnOrderEvent(self, order_event: OrderEvent) -> None:
    if order_event.Status == OrderStatus.Canceled:
        ticket = self.Transactions.GetOrderTicket(order_event.OrderId)
        if "symbol changed event" in ticket.Tag:
            self.Transactions.AddOrder(ticket.SubmitRequest)
```

LEAN stores the data for ticker changes in map files. To view some example map files, see the LEAN GitHub repository .

Delistings

When a company is delisting from an exchange, LEAN sends a `Delisting` object to the `OnData` method. `Delisting` objects have the following properties:

You receive `Delisting` objects when a delisting is in the near future and when it occurs. To know if the delisting occurs in the near future or now, check the `Type` property.

To get the `Delisting` objects in the `Slice` , index the `Delistings` property of the `Slice` with the security `Symbol` . The `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Delistings` property contains data for your security before you index it with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    delisting = slice.Delistings.get(self.symbol)
    if delisting:
        pass
```

You can also iterate through the `Delistings` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Delisting` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, delisting in slice.Delistings.items():
        pass
```

The delist warning occurs on the final trading day of the stock to give you time to gracefully exit out of positions before LEAN automatically liquidates them.

```py
if delisting.Type == DelistingType.Warning:
    # Liquidate with MarketOnOpenOrder on delisting warning
    quantity = self.Portfolio[symbol].Quantity
    if quantity != 0:
        self.MarketOnOpenOrder(symbol, -quantity)
```

For a full example, see the DelistingEventsAlgorithm in the LEAN GitHub repository.

India Equity

Data Preparation

Introduction

The India Equities dataset provides price data for backtests.

Sourcing

TrueData is an authorized NSE and MCX data vendor founded by Kapil Marwaha in 2007, with the goal of providing users with a multitude of solutions for the financial services sector, including making market data feeds available in all its forms, to as many applications as possible, including a wide range of technical analysis applications, trading solutions, automated & algorithmic traders/platforms and a lot more.

Bar Building

We receive minute-resolution trade data and aggregate it to build hour and daily bars. To create custom resolution periods, see Consolidating Data .

India Equity

Market Hours

Introduction

This page shows the trading hours, holidays, and time zone of the India Equity market.

Pre-market Hours

The following table shows the pre-market hours for the India Equity market:

Weekday	Time (Asia/Kolkata)
Monday	09:00:00 to 09:15:00
Tuesday	09:00:00 to 09:15:00
Wednesday	09:00:00 to 09:15:00
Thursday	09:00:00 to 09:15:00
Friday	09:00:00 to 09:15:00

Regular Trading Hours

The following table shows the regular trading hours for the India Equity market:

Weekday	Time (Asia/Kolkata)
Monday	09:15:00 to 15:30:00
Tuesday	09:15:00 to 15:30:00
Wednesday	09:15:00 to 15:30:00
Thursday	09:15:00 to 15:30:00
Friday	09:15:00 to 15:30:00

Post-market Hours

The following table shows the post-market hours for the India Equity market:

Weekday	Time (Asia/Kolkata)
Monday	15:40:00 to 16:00:00
Tuesday	15:40:00 to 16:00:00
Wednesday	15:40:00 to 16:00:00
Thursday	15:40:00 to 16:00:00
Friday	15:40:00 to 16:00:00

Holidays

The following table shows the dates of holidays for the India Equity market:

Date (*yyyy-mm-dd*)				
2004-01-26	2004-04-14	2005-01-26	2005-04-14	2005-08-15

Early Closes

There are no days with early closes.

Late Opens

There are no days with late opens.

Time Zone

The India Equity market trades in the `Asia/Kolkata` time zone.

Asset Classes

Equity Options

Equity Options are a financial derivative that gives the holder the right (but not the obligation) to buy or sell the underlying Equity, such as Apple, at the stated exercise price.

Requesting Data

Equity Options

Requesting Data

Introduction

Request Equity Options data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Equity Options dataset listing . To trade Equity Options live, you can use one of the brokerage data feeds . We currently only support American-style Options for US Equity Options.

Create Subscriptions

Before you can subscribe to an Option contract, you must configure the underlying Equity and get the contract `Symbol` .

Configure the Underlying Equity

If you want to subscribe to the underlying Equity in the `Initialize` method, set the Equity data normalization to `DataNormalizationMode.Raw` .

```
self.symbol = self.AddEquity("SPY", dataNormalizationMode=DataNormalizationMode.Raw).Symbol
```

If your algorithm has a dynamic universe of Equities, before you add the Equity universe in the `Initialize` method, set the universe data normalization mode to `DataNormalizationMode.Raw` .

```
self.UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw
```

If you subscribe to an Equity Option contract but don't have a subscription to the underlying Equity, LEAN automatically subscribes to the underlying Equity with the following settings:

Setting	Value
Fill forward	Same as the Option contract
Leverage	0
Extended Market Hours	Same as the Option contract
Data Normalization	`DataNormalizationMode.Raw`

In this case, you still need the Equity `Symbol` to subscribe to Equity Option contracts. If you don't have access to it, create it.

```
self.symbol = Symbol.Create("SPY", SecurityType.Equity, Market.USA)
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Get Contract Symbols

To subscribe to an Option contract, you need the contract `Symbol` . You can get the contract `Symbol` from the `CreateOption` method or from the `OptionChainProvider` . If you use the `CreateOption` method, you need to provide the details of an existing contract.

```
self.contract_symbol = Symbol.CreateOption(self.symbol, Market.USA,
    OptionStyle.American, OptionRight.Call, 365, datetime(2022, 6, 17))
```

Another way to get an Option contract `Symbol` is to use the `OptionChainProvider` . The `GetOptionContractList` method of `OptionChainProvider` returns a list of `Symbol` objects that reference the available Option contracts for a given underlying Equity on a given date. To filter and select contracts, you can use the following properties of each `Symbol` object:

Property	Description
`ID.Date`	The expiration date of the contract.
`ID.StrikePrice`	The strike price of the contract.
`ID.OptionRight`	The contract type. The `OptionRight` enumeration has the following members:
`ID.OptionStyle`	The contract style. The `OptionStyle` enumeration has the following members: We currently only support American-style Options for US Equity Options.

```
contract_symbols = self.OptionChainProvider.GetOptionContractList(self.symbol, self.Time)
expiry = min([symbol.ID.Date for symbol in contract_symbols])
filtered_symbols = [symbol for symbol in contract_symbols if symbol.ID.Date == expiry and
symbol.ID.OptionRight == OptionRight.Call]
self.contract_symbol = sorted(filtered_symbols, key=lambda symbol: symbol.ID.StrikePrice)[0]
```

Subscribe to Contracts

To create an Equity Option contract subscription, pass the contract `Symbol` to the `AddOptionContract` method. Save a reference to the contract `Symbol` so you can easily access the Option contract in the OptionChain that LEAN passes to the `OnData` method. This method returns an `Option` object. To override the default pricing model of the Option, set a pricing model .

```
option = self.AddOptionContract(self.contract_symbol)
option.PriceModel = OptionPriceModels.BjerksundStensland()
```

The `AddOptionContract` method creates a subscription for a single Option contract and adds it to your **user-defined** universe. To create a dynamic universe of Option contracts, add an Equity Options universe or an Options Universe Selection model .

Warm Up Contract Prices

If you subscribe to an Option contract with `AddOptionContract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
PY
seeder = FuncSecuritySeeder(self.GetLastKnownPrices)
self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel, seeder, self))
```

Supported Assets

To view the supported assets in the US Equities dataset, see the Data Explorer .

Resolutions

The following table shows the available resolutions and data formats for Equity Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				
`Second`				
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Option contract subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddOptionContract` method.

```
PY
self.AddOptionContract(self.contract_symbol, Resolution.Minute)
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

LEAN groups all of the US Equity exchanges under `Market.USA` . You don't need to pass a `Market` argument to the `AddOptionContract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.AddOptionContract(self.contract_symbol, fillForward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Options are already leveraged products, so you can't change their leverage.

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
self.AddOptionContract(self.contract_symbol, extendedMarketHours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Remove Subscriptions

To remove a contract subscription that you created with `AddOptionContract` , call the `RemoveOptionContract` method. This method is an alias for `RemoveSecurity` .

```
self.RemoveOptionContract(self.contract_symbol)
```

The `RemoveOptionContract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `AddOptionContract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and the `Security` object for its underlying in any function, use the Option `Symbol` to access the value in the `Securities` object.

```
option = self.Securities[self.contract_symbol]
underlying = self.Securities[self.contract_symbol.Underlying]
underlying_price = underlying.Price
```

To get the Option payoff , call the `GetPayOff` method.

```py
pay_off = option.GetPayOff(underlying_price)
```

To get the Option intrinsic value , call the `GetIntrinsicValue` method.

```py
intrinsic_value = option.GetIntrinsicValue(underlying_price)
```

To get the Option out-of-the-money amount , call the `OutOfTheMoneyAmount` method.

```py
otm_amount = option.OutOfTheMoneyAmount(underlying_price)
```

To check whether the Option can be automatic exercised, call the `IsAutoExercised` method.

```py
is_auto_exercised = option.IsAutoExercised(underlying_price)
```

Equity Options

Handling Data

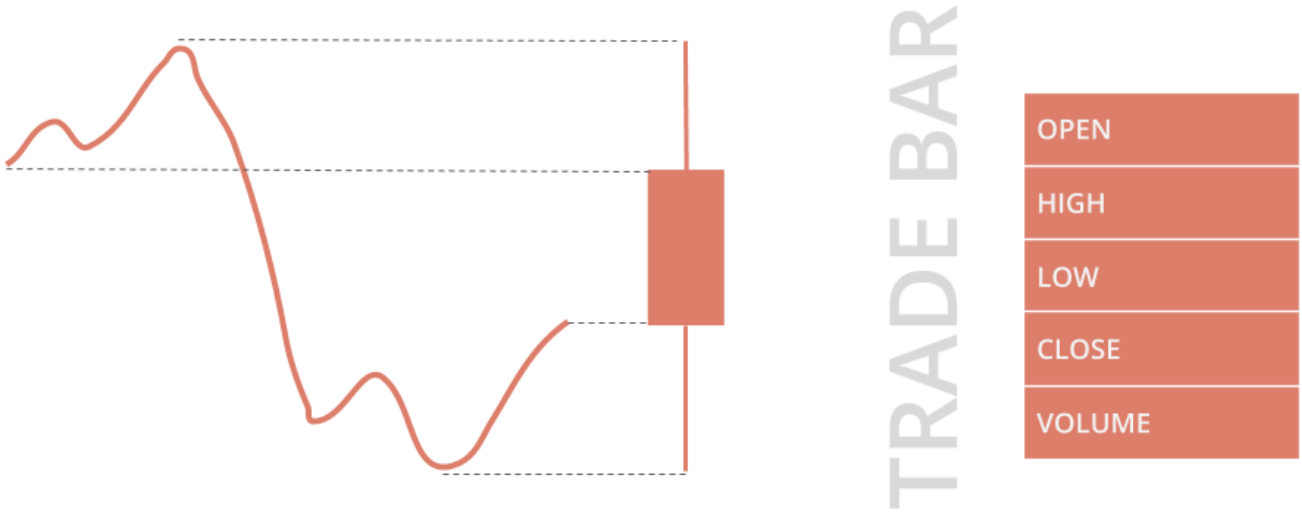
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `Symbol` , but we recommend you use the `Symbol` .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

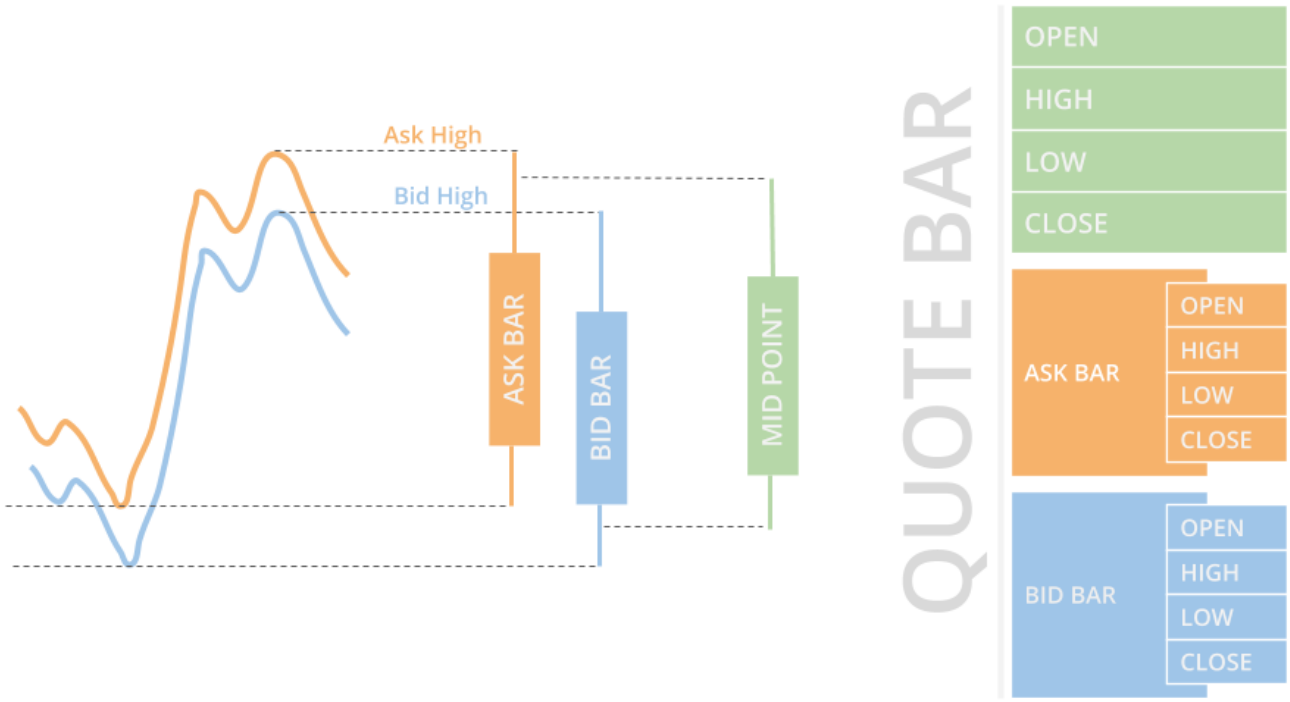
```
def OnData(self, slice: Slice) -> None:
    if self.contract_symbol in slice.Bars:
        trade_bar = slice.Bars[self.contract_symbol]
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        close_price = trade_bar.Close
```

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.contract_symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.contract_symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security. They have the following properties:

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contracts = chain.Contracts
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```
def OnData(self, slice: Slice) -> None:
    for canonical_symbol, chain in slice.OptionChains.items():
        contracts = chain.Contracts
```

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. They have the following properties:

To get the Option contracts in the `Slice` , use the `Contracts` property of the `OptionChain` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            price = contract.Price
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `Greeks` and `ImpliedVolatility` members.

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            delta = contract.Greeks.Delta
            iv = contract.ImpliedVolatility
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `Greeks` member, the Greeks aren't calculated. However, if you invoke the `Greeks.Delta` member, LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `OpenInterest` property of the `Option` or `OptionContract` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            open_interest = contract.OpenInterest
```

Equity Options

Market Hours

Introduction

This page shows the trading hours, holidays, and time zone of the Equity Option market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the Equity Option market:

Weekday	**Time (America/New York)**
Monday	09:30:00 to 16:00:00
Tuesday	09:30:00 to 16:00:00
Wednesday	09:30:00 to 16:00:00
Thursday	09:30:00 to 16:00:00
Friday	09:30:00 to 16:00:00

Post-market Hours

Post-market trading is not available.

Holidays

LEAN uses the trading holidays from the NYSE website.

The following table shows the dates of holidays for the Equity Option market:

Date (*yyyy-mm-dd*)				
1998-01-01	1998-01-19	1998-02-16	1998-04-10	1998-05-25
1998-07-03	1998-09-07	1998-11-26	1998-12-25	1999-01-01
1999-01-18	1999-02-15	1999-04-02	1999-05-31	1999-07-05
1999-09-06	1999-11-25	1999-12-24	2000-01-17	2000-02-21
2000-04-21	2000-05-29	2000-07-04	2000-09-04	2000-11-23

Date (*yyyy-mm-dd*)

Late Opens

There are no days with late opens.

Time Zone

The Equity Option market trades in the `America/New York` time zone.

Asset Classes

Crypto

A Cryptocurrency is a digital currency that's secured by cryptography, which makes it nearly impossible to counterfeit or double-spend.

Crypto

Requesting Data

Introduction

Request Crypto data in your algorithm to receive a feed of asset prices in the `OnData` method. For more information about the specific datasets we use for backtests, see the CoinAPI datasets . To trade Crypto live, you can use our Crypto data feed .

Create Subscriptions

To create a Crypto subscription, in the `Initialize` method, call the `AddCrypto` method. The `AddCrypto` method returns a `Crypto` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
self.symbol = self.AddCrypto("BTCUSD").Symbol
```

The `AddCrypto` method creates a subscription for a single Crypto asset and adds it to your **user-defined** universe. To create a dynamic universe of Crypto assets, add a Crypto universe .

To view the supported assets, see the CoinAPI datasets .

Fungible Assets

Fungible assets are assets that are interchangeable with each other. For example, every Bitcoin is effectively identical to every other Bitcoin. In contrast, non-fungible tokens (NFTs) are non-fungible because each one is unique. An example of an NFT is the Bored Ape Yacht Club collection. LEAN doesn't currently support trading NFTs.

Resolutions

The following table shows the available resolutions and data formats for Crypto subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	✓
`Second`	✓	✓		
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Crypto subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution`

argument to the `AddCrypto` method.

```
self.symbol = self.AddCrypto("BTCUSD", Resolution.Daily).Symbol
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Crypto:

To set the market for a security, pass a `market` argument to the `AddCrypto` method.

```
self.symbol = self.AddCrypto("BTCUSD", market=Market.GDAX).Symbol
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.symbol = self.AddCrypto("BTCUSD", fillForward=False).Symbol
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The amount of leverage available to you depends on the brokerage you use. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `AddCrypto` method.

```
self.symbol = self.AddCrypto("BTCUSD", leverage=3).Symbol
```

For more information about the leverage each brokerage provides, see Brokerages .

Properties

The `AddCrypto` method returns a `Crypto` object, which have the following properties:

Crypto

Handling Data

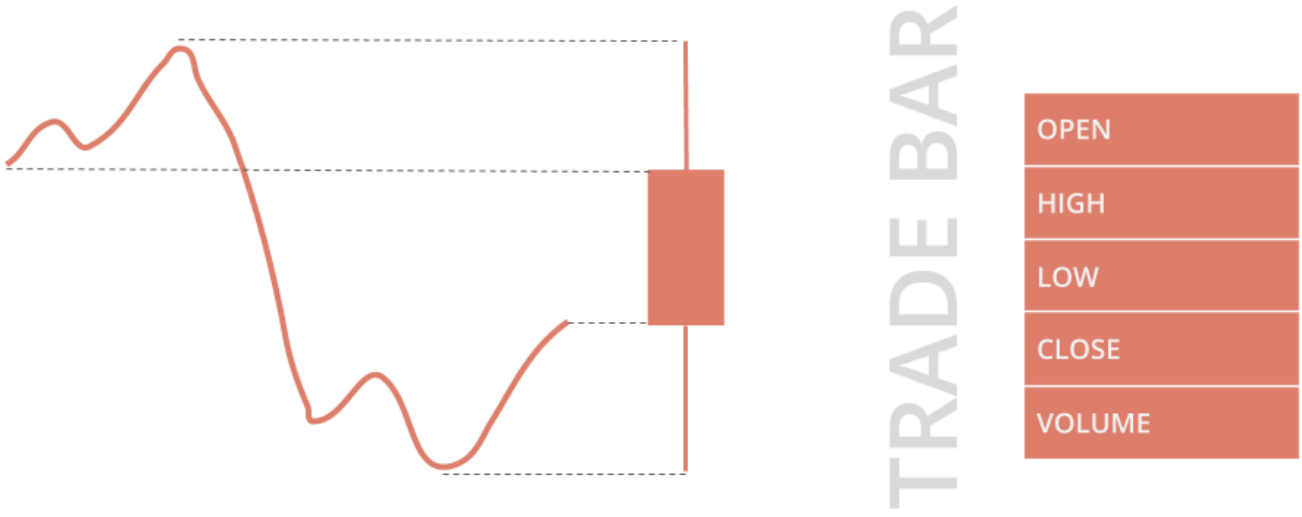
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `Symbol` , but we recommend you use the `Symbol` .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the security `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

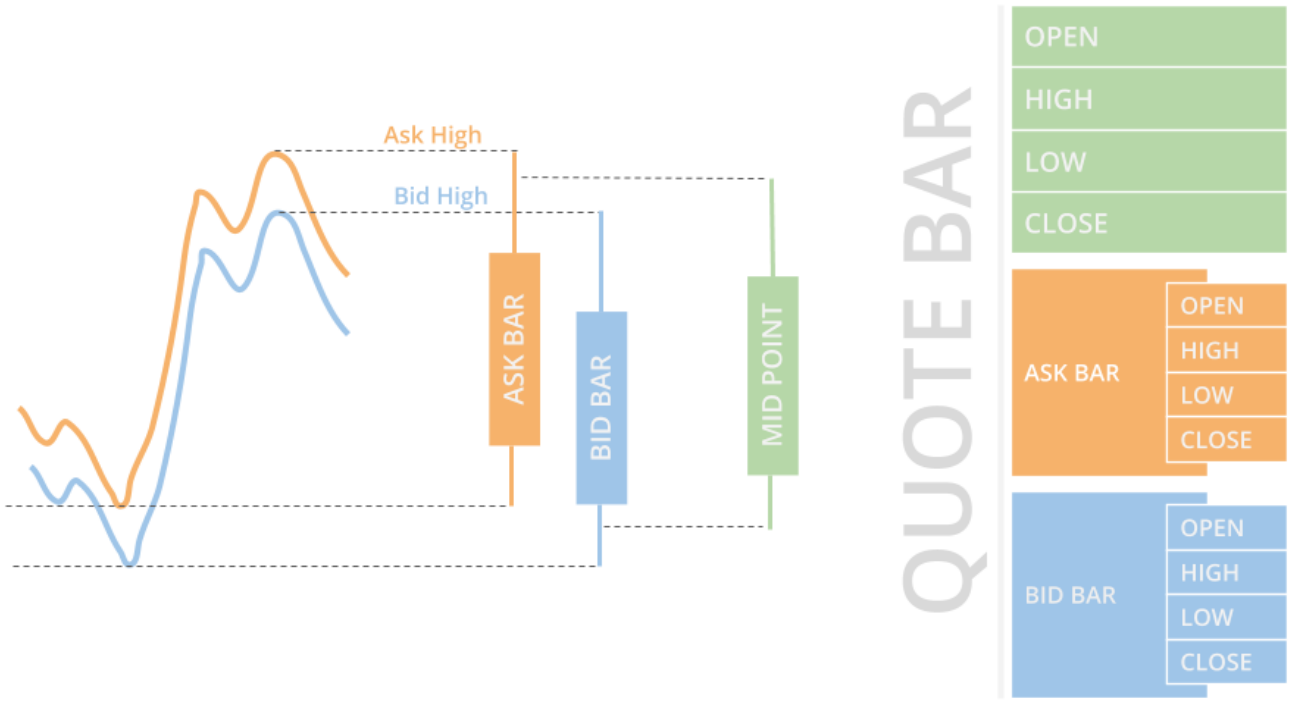
```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        close_price = trade_bar.Close
```

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the security `Symbol` . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price. `Tick` objects have the following properties:

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            price = tick.Price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            price = tick.Price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able

to perform your own online tick filtering.

Crypto

Holdings

Introduction

Crypto holdings require special consideration because not all brokerages track your positions in each currency pair.

Cash vs Margin Brokerage Accounts

Some of the Crypto brokerages integrated into QuantConnect support cash and margin accounts while some only support cash accounts. If you want to short Crypto assets or use leverage, you need a margin account. Follow these steps to view which account types each brokerage supports:

1. Open the brokerage guides .
2. Click a Crypto brokerage.
3. Scroll down to the **Account Types** section.

Virtual Pairs

All fiat and Crypto currencies are individual assets. When you buy a pair like BTCUSD, you trade USD for BTC. In this case, LEAN removes some USD from your portfolio cashbook and adds some BTC. The virtual pair BTCUSD represents your position in that trade, but the virtual pair doesn't actually exist. It simply represents an open trade. If you call the Liquidate method with the `Symbol` of a virtual pair, the method only liquidates the quantity in your virtual pair. For more information about liquidating Crypto postitions, see Crypto Trades .

Access Cypto Holdings

The `CashBook` stores the quantity of your Crypto holdings. To access your Crypto holdings, index the `CashBook` with the currency ticker. The values of the `CashBook` dictionary are `Cash` objects, which have the following properties:

```
PY
btc_quantity = self.Portfolio.CashBook['BTC'].Amount
btc_value = self.Portfolio.CashBook['BTC'].ValueInAccountCurrency
```

To access the virtual pair of your Crypto trades, index the `Portfolio` object with the pair `Symbol` .

```
PY
security_holding  = self.Portfolio[self.btc_usd_symbol]
```

Stateful Redeployments

When you make a trade inside of a running algorithm, LEAN tracks the virtual position state for you, but it won't survive between deployments. Some brokerages save your virtual pairs, so you can load them into your algorithm when you stop and redeploy it. Depending on the brokerage you select, you may be able to manually add virtual pairs when you deploy live algorithms with the LEAN CLI or cloud deployment wizard .

Crypto

Market Hours

Introduction

The Crypto markets are open 24/7. There are no pre-market hours, post-market hours, holidays, late opens, or early closes.

Asset Classes

Crypto Futures

Crypto Perpetual Futures are derivative financial contracts that obligate parties to buy or sell an asset at an unspecified future date.

Crypto Futures

Requesting Data

Introduction

Request Crypto Futures data in your algorithm to receive a feed of asset prices in the `OnData` method. For more information about the specific datasets we use for backtests, see the Binance Crypto Future Price Data dataset listing . To trade Crypto live, you can use our Crypto Futures data feed .

Create Subscriptions

To create a Crypto Futures subscription, in the `Initialize` method, call the `AddCryptoFuture` method. The `AddCryptoFuture` method returns a `CryptoFuture` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
self.symbol = self.AddCryptoFuture("BTCUSD").Symbol
```

The `AddCryptoFuture` method creates a subscription for a single Crypto Futures asset and adds it to your **user-defined** universe.

To view the supported assets in the Crypto Futures dataset, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Crypto Futures contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	✓
`Second`	✓	✓		
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Crypto Futures subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddCryptoFuture` method.

```
self.symbol = self.AddCryptoFuture("BTCUSD", Resolution.Daily).Symbol
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

Crypto Futures are currently only available on `Market.Binance` . To set the market for a security, pass a `market` argument to the `AddCryptoFuture` method.

```
self.symbol = self.AddCryptoFuture("BTCUSD", market=Market.Binance).Symbol
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.symbol = self.AddCryptoFuture("BTCUSD", fillForward=False).Symbol
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The amount of leverage available to you depends on the brokerage you use. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `AddCryptoFuture` method.

```
self.symbol = self.AddCryptoFuture("BTCUSD", leverage=3).Symbol
```

For more information about the leverage each brokerage provides, see Brokerages .

Properties

The `AddCryptoFuture` method returns a `CryptoFuture` object, which have the following properties:

Crypto Futures

Handling Data

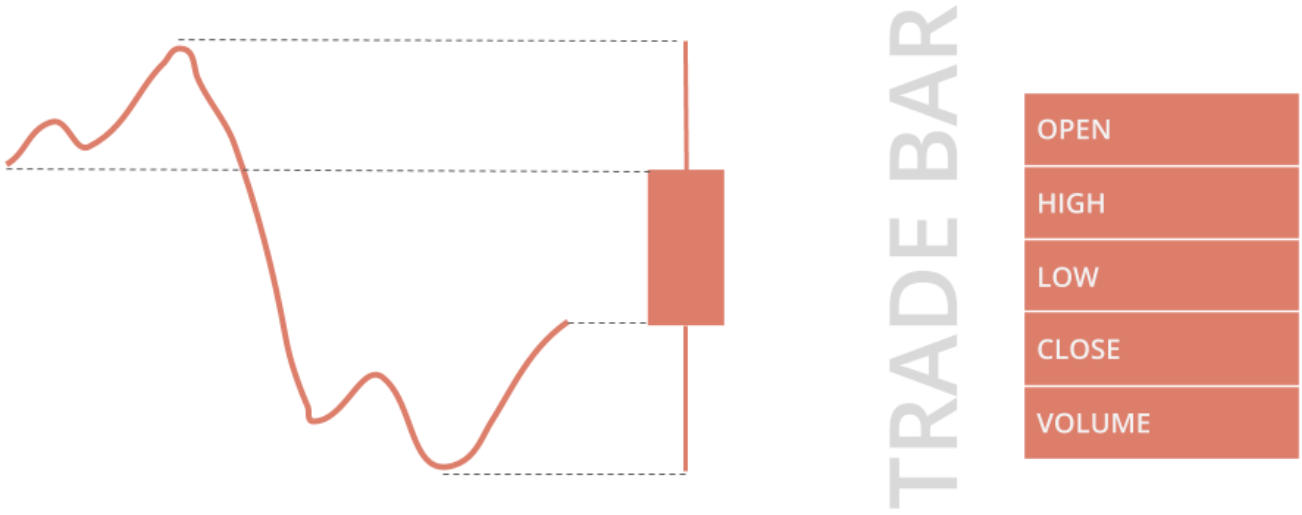
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `Symbol` , but we recommend you use the `Symbol` .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the security `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

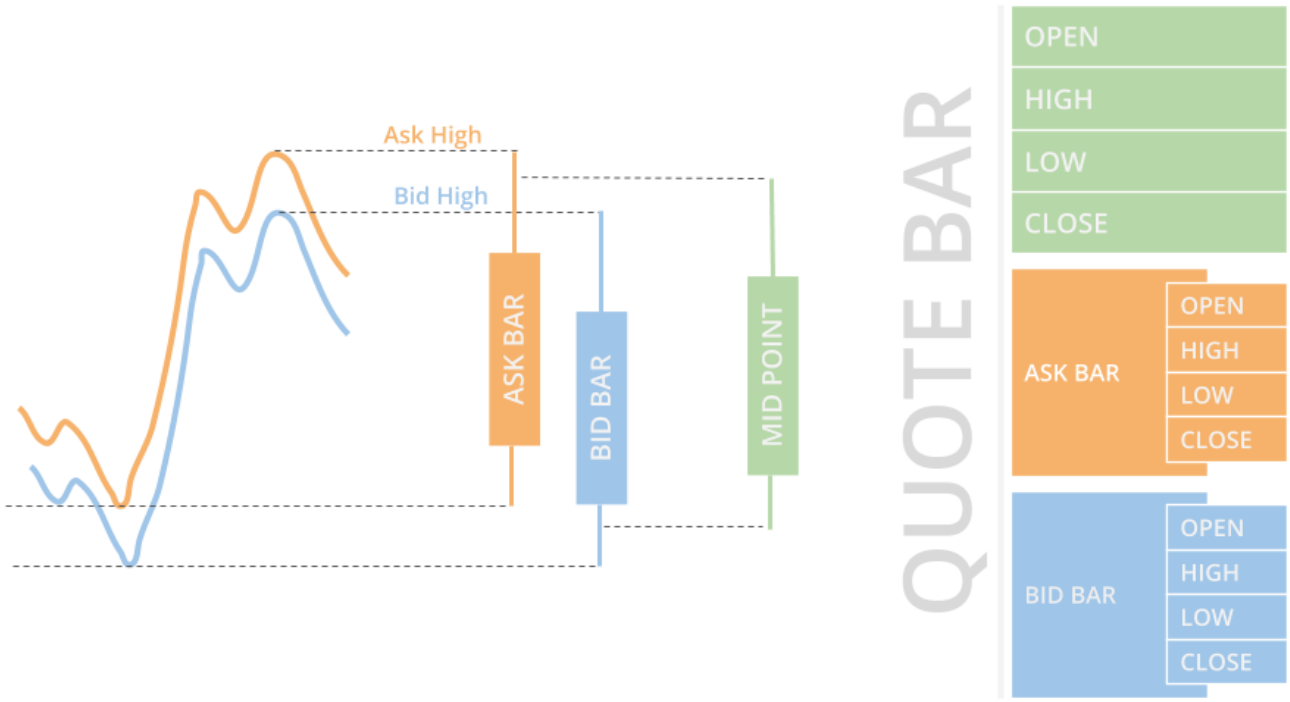
```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        close_price = trade_bar.Close
```

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the security `Symbol` . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price. `Tick` objects have the following properties:

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            price = tick.Price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            price = tick.Price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able

to perform your own online tick filtering.

Margin Interest Rates

`MarginInterestRate` objects contain the margin interest rate, which is a cost associated with trading on margin. `MarginInterestRate` objects have the following properties:

To get the `MarginInterestRate` objects in the `Slice` , index the `MarginInterestRate` property of the `Slice` with the Crypto Future `Symbol` . The `MarginInterestRate` property of the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the property contains data for your Crypto Future before you index it with the Crypto Future `Symbol` .

```
PY
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.MarginInterestRates:
        interest_rate = slice.MarginInterestRates[self.symbol].InterestRate
```

You can also iterate through the `MarginInterestRates` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `MarginInterestRate` objects.

```
PY
def OnData(self, slice: Slice) -> None:
    for symbol, margin_interest_rate in slice.MarginInterestRates.items():
        interest_rate = margin_interest_rate.InterestRate
```

Crypto Futures

Market Hours

Introduction

The Crypto Futures markets are open 24/7. There are no pre-market hours, post-market hours, holidays, late opens, or early closes.

Asset Classes

Forex

Forex markets are for trading foreign currencies.

Forex

Requesting Data

Introduction

Request Forex data in your algorithm to receive a feed of exchange rates in the `OnData` method. For more information about the specific dataset we use for backtests, see the FOREX dataset listing . To trade Forex live, you can use our Forex data feed .

Create Subscriptions

To create a Forex pair subscription, in the `Initialize` method, call the `AddForex` method. The `AddForex` method returns a `Forex` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
self.symbol = self.AddForex("EURUSD").Symbol
```

To view the supported Forex pairs, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Forex subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				✓
`Second`		✓		
`Minute`		✓		
`Hour`		✓		
`Daily`		✓		

The default resolution for Forex subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddForex` method.

```
self.symbol = self.AddForex("EURUSD", Resolution.Daily).Symbol
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for Forex pairs is `Market.Oanda` , so you don't need to pass a `market` argument to the `AddForex` method.

```
self.symbol = self.AddForex("EURUSD", market=Market.Oanda).Symbol
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.symbol = self.AddForex("EURUSD", fillForward=False).Symbol
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The Oanda brokerage let's you use up to 50x leverage on margin accounts. To change the amount of leverage you can use for a Forex pair, pass a `leverage` argument to the `AddForex` method.

```
self.symbol = self.AddForex("EURUSD", leverage=35).Symbol
```

Properties

The `AddForex` method returns a `Forex` object, which have the following properties:

Forex

Handling Data

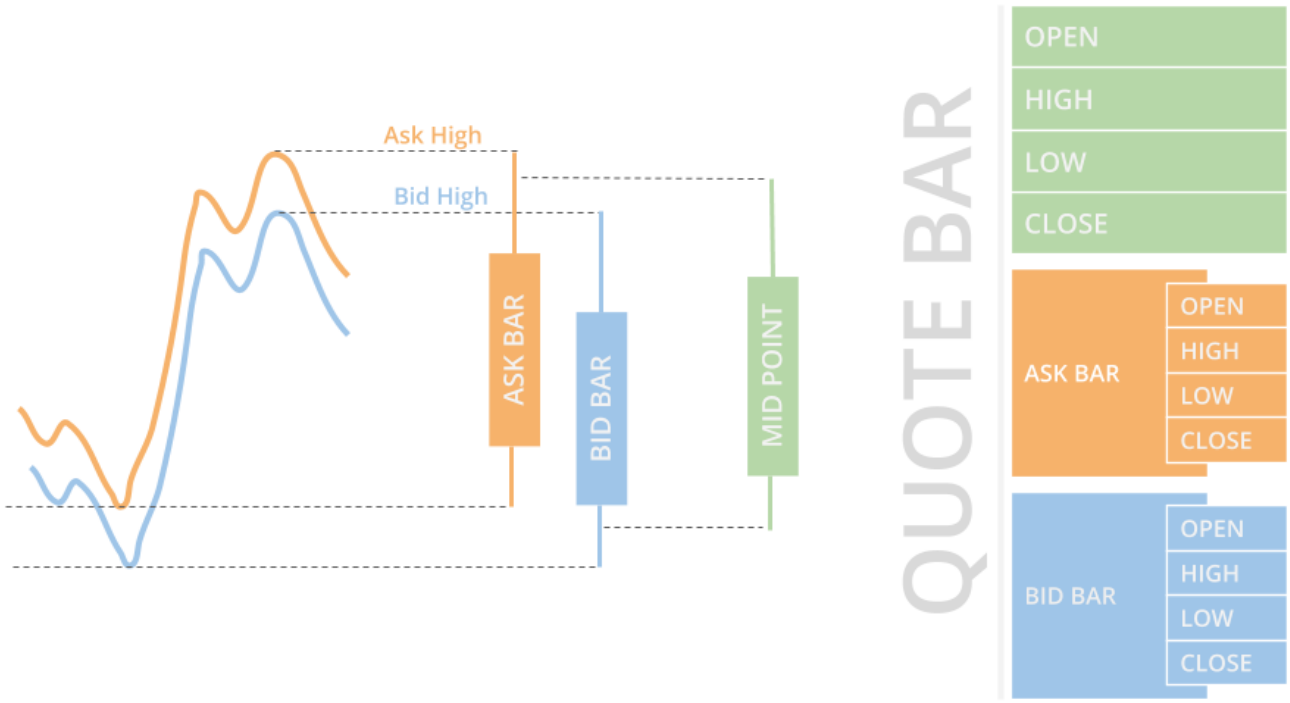
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `QuoteBars DataDictionary` is made up of `QuoteBar` objects. To access individual data points in the dictionary, you can index the dictionary with the Forex pair ticker or `Symbol` , but we recommend you use the `Symbol` .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the Forex pair `Symbol` . If the Forex pair doesn't actively get quotes or you are in the same time step as when you added the Forex pair subscription,

the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your Forex pair before you index the `Slice` with the Forex pair `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the Forex pair. A quote tick is an offer to buy or sell the Forex pair at a specific price. `Tick` objects have the following properties:

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the Forex pair doesn't actively trade or you are in the same time step as when you added the Forex pair subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your Forex pair before you index the `Slice` with the Forex pair `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            price = tick.Price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```py
def OnData(self, slice: Slice) -> None:
    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            price = tick.Price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

Futures

Requesting Data

Introduction

Request Futures data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Futures dataset listing . To trade Futures live, you can use our Futures data feed or one of the brokerage data feeds .

Create Subscriptions

Before you can subscribe to a Futures contract, you must get the contract `Symbol` .

Get Contract Symbols

To get Futures contract `Symbol` objects, call the `CreateFuture` method or use the `FutureChainProvider` . If you use the `CreateFuture` method, you need to know the specific contract details.

```
PY
self.contract_symbol = Symbol.CreateFuture(Futures.Indices.SP500EMini,
    Market.CME, datetime(2022,6,17))
```

If you use the `FutureChainProvider` , you need to create the continuous contract `Symbol` of the Future. The `GetFutureContractList` method of `FutureChainProvider` returns a list of `Symbol` objects that reference the available Futures contracts for a given underlying Future on a given date.

```
PY
continuous_future_symbol = Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME)
contract_symbols = self.FutureChainProvider.GetFutureContractList(continuous_future_symbol, self.Time)
self.contract_symbol = sorted(contract_symbols, key=lambda symbol: symbol.ID.Date)[0]
```

Subscribe to Contracts

To create a Futures contract subscription, pass the contract `Symbol` to the `AddFutureContract` method. Save a reference to the contract `Symbol` so you can easily access the contract in the FuturesChain that LEAN passes to the `OnData` method.

```
PY
self.AddFutureContract(self.contract_symbol)
```

The `AddFutureContract` method creates a subscription for a single Future contract and adds it to your **user-defined** universe. To create a dynamic universe of Futures contracts, add a Futures universe or a Futures Universe Selection model .

Warm Up Contract Prices

If you subscribe to a Futures contract with `AddFutureContract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel,
    FuncSecuritySeeder(self.GetLastKnownPrices)));
```

PY

Supported Assets

To view the supported assets in the US Futures dataset, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Futures subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	✓
`Second`	✓	✓		
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Futures contract subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddFutureContract` method.

```
self.AddFutureContract(self.contract_symbol, Resolution.Daily)
```

PY

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Futures:

You don't need to pass a `market` argument to the `AddFutureContract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.AddFutureContract(self.contract_symbol, fillForward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Futures are already leveraged products, so you can't change their leverage with the default margin model .

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
self.AddFutureContract(self.contract_symbol, extendedMarketHours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

In general, we model most Futures market hours with the following segments:

Market Segment	Time
Pre-market	00:00:00 to 09:30:00
Market	09:30:00 to 17:00:00
Post-market	18:00:00 to 00:00:00

We model it this way because some Futures, like VIX, have pre- and post-market hours, so we standardized it. With this segmentation, if you set a Scheduled Events for the market open, it's set for 9:30 AM instead of midnight.

Continuous Contracts

A continuous Futures contract represents a single contract that maps to other contracts over time as the rollover rules are met. For more information about continuous Futures contracts, see Continuous Contracts .

Properties

The `AddFutureContract` method returns a `Future` object, which have the following properties:

Futures

Handling Data

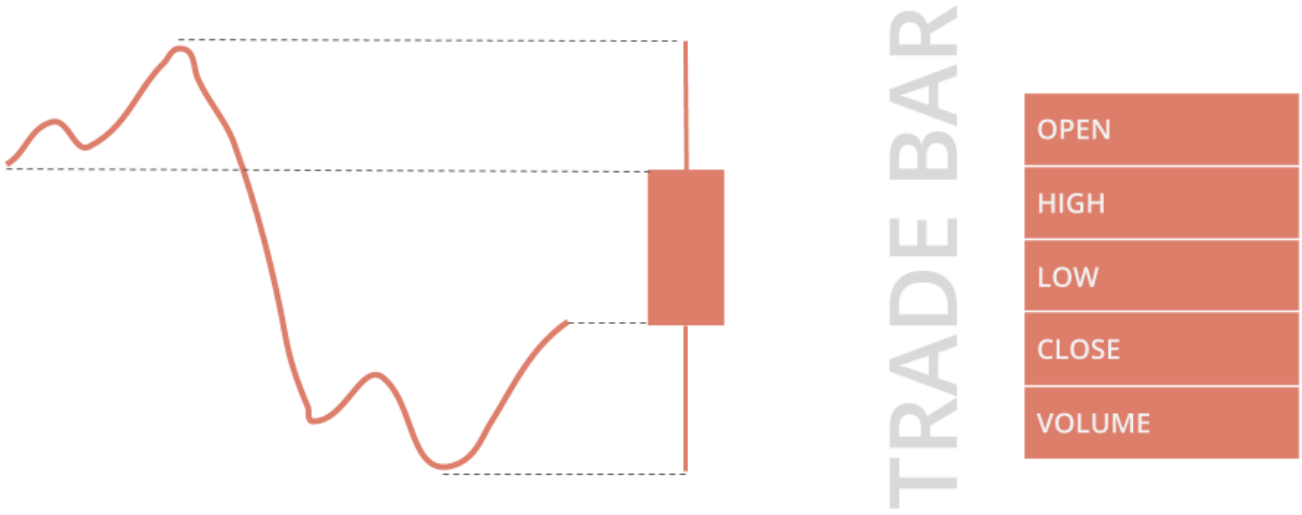
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `Symbol` , but we recommend you use the `Symbol` .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

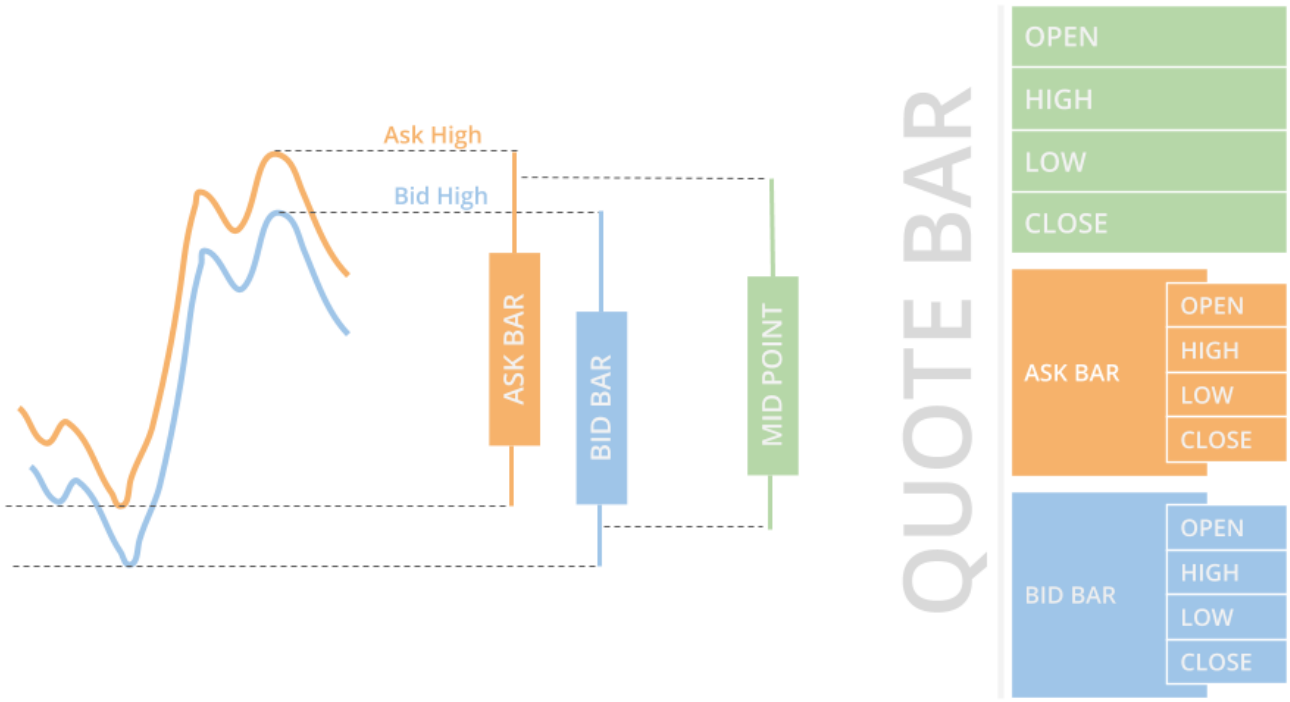
```
def OnData(self, slice: Slice) -> None:
    if self.contract_symbol in slice.Bars:
        trade_bar = slice.Bars[self.contract_symbol]
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        close_price = trade_bar.Close
```

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.contract_symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.contract_symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the contract. A quote tick is an offer to buy or sell the contract at a specific price. `Tick` objects have the following properties:

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.contract_symbol in slice.Ticks:
        ticks = slice.Ticks[self.contract_symbol]
        for tick in ticks:
            price = tick.Price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            price = tick.Price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able

to perform your own online tick filtering.

Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. They have the following properties:

To get the `FuturesChain` , index the `FuturesChains` property of the `Slice` with the continuous contract `Symbol` .

```
PY
def OnData(self, slice: Slice) -> None:
    chain = slice.FuturesChains.get(self.contract_symbol.Canonical)
    if chain:
        contracts = chain.Contracts
```

You can also loop through the `FuturesChains` property to get each `FuturesChain` .

```
PY
def OnData(self, slice: Slice) -> None:
    for continuous_contract_symbol, chain in slice.FuturesChains.items():
        contracts = chain.Contracts
```

Futures Contracts

`FuturesContract` objects represent the data of a single Futures contract in the market. They have the following properties:

To get the Futures contracts in the `Slice` , use the `Contracts` property of the `FuturesChain` .

```
PY
def OnData(self, slice: Slice) -> None:
    chain = slice.FuturesChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            price = contract.LastPrice
```

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `OpenInterest` property of the `Future` or `FutureContract` .

```
PY
def OnData(self, slice: Slice) -> None:
    chain = slice.FuturesChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            open_interest = contract.OpenInterest
```

Symbol Changes

When the continuous contract rolls over, LEAN passes a `SymbolChangedEvent` to your `OnData` method, which contains the old contract `Symbol` and the new contract `Symbol` . `SymbolChangedEvent` objects have the following properties:

To get the `SymbolChangedEvent` , use the `SymbolChangedEvents` property of the `Slice` .

```py
def OnData(self, slice: Slice) -> None:
    for changed_event in slice.SymbolChangedEvents.Values:
        self.Log(f"Contract rollover from {changed_event.OldSymbol} to {changed_event.NewSymbol}")
```

CBOT

Introduction

This page shows the trading hours, holidays, and time zone of the CBOT Future market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the CBOT Future market:

Weekday	**Time (America/Chicago)**
Sunday	18:00:00 to 24:00:00
Monday	00:00:00 to 24:00:00
Tuesday	00:00:00 to 24:00:00
Wednesday	00:00:00 to 24:00:00
Thursday	00:00:00 to 24:00:00
Friday	00:00:00 to 16:00:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the CBOT Future market:

Date (*yyyy-mm-dd*)				
1998-01-01	1998-01-19	1998-02-16	1998-04-10	1998-05-25

Date (*yyyy-mm-dd*)

Early Closes

There are no days with early closes.

Late Opens

There are no days with late opens.

Time Zone

The CBOT Future market trades in the following time zones:

- `America/Chicago`
- `America/New York`

Assets With Other Hours

The following table shows the contracts that have different trading periods than the overall CBOT Future market:

Symbol	Name
10Y	Micro 10-Year Yield Futures
2YY	Micro 2-Year Yield Futures
30Y	Micro 30-Year Yield Futures
5YY	Micro 5-Year Yield Futures
AW	Bloomberg Commodity Index Futures
BCF	Black Sea Corn Financially Settled (Platts) Futures
BWF	Black Sea Wheat Financially Settled (Platts) Futures
EH	Ethanol Futures
F1U	5-Year USD MAC Swap Futures
KE	KC HRW Wheat Futures
MYM	Micro E-mini Dow Jones Industrial Average Index Futures
TN	Ultra 10-Year U.S. Treasury Note Futures
UB	Ultra U.S. Treasury Bond Futures
YM	E-mini Dow ($5) Futures
ZB	U.S. Treasury Bond Futures
ZC	Corn Futures
ZF	5-Year T-Note Futures
ZL	Soybean Oil Futures
ZM	Soybean Meal Futures
ZN	10-Year T-Note Futures
ZO	Oats Futures
ZS	Soybean Futures
ZT	2-Year T-Note Futures
ZW	Chicago SRW Wheat Futures

Introduction

This page shows the trading hours, holidays, and time zone of the Micro 10-Year Yield Futures contract in the CBOT Future market.

Pre-market Hours

The following table shows the pre-market hours for the Micro 10-Year Yield Futures contract in the CBOT Future market:

Weekday	Time (America/Chicago)
Sunday	17:00:00 to 24:00:00
Monday	00:00:00 to 08:30:00
Tuesday	00:00:00 to 08:30:00
Wednesday	00:00:00 to 08:30:00
Thursday	00:00:00 to 08:30:00
Friday	00:00:00 to 08:30:00

Regular Trading Hours

The following table shows the regular trading hours for the Micro 10-Year Yield Futures contract in the CBOT Future market:

Weekday	Time (America/Chicago)
Monday	08:30:00 to 16:00:00
Tuesday	08:30:00 to 16:00:00
Wednesday	08:30:00 to 16:00:00
Thursday	08:30:00 to 16:00:00
Friday	08:30:00 to 16:00:00

Post-market Hours

The following table shows the post-market hours for the Micro 10-Year Yield Futures contract in the CBOT Future market:

Weekday	Time (America/Chicago)
Monday	17:00:00 to 24:00:00
Tuesday	17:00:00 to 24:00:00
Wednesday	17:00:00 to 24:00:00
Thursday	17:00:00 to 24:00:00

Holidays

The following table shows the dates of holidays for the CBOT Future market:

Date (*yyyy-mm-dd*)				
1998-01-01	1998-01-19	1998-02-16	1998-04-10	1998-05-25

Late Opens

There are no days with late opens.

Time Zone

The SGX Nikkei 225 Index Futures contract in the SGX Future market trades in the `Asia/Singapore` time zone.

SGX

TW

Introduction

This page shows the trading hours, holidays, and time zone of the MSCI Taiwan Index Futures contract in the SGX Future market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the MSCI Taiwan Index Futures contract in the SGX Future market:

Weekday	Time (Asia/Singapore)
Monday	08:30:00 to 13:50:00, 14:05:00 to 24:00:00
Tuesday	00:00:00 to 05:15:00, 08:30:00 to 13:50:00, 14:05:00 to 24:00:00
Wednesday	00:00:00 to 05:15:00, 08:30:00 to 13:50:00, 14:05:00 to 24:00:00
Thursday	00:00:00 to 05:15:00, 08:30:00 to 13:50:00, 14:05:00 to 24:00:00
Friday	00:00:00 to 05:15:00, 08:30:00 to 13:50:00, 14:05:00 to 24:00:00
Saturday	00:00:00 to 05:15:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the MSCI Taiwan Index Futures contract in the SGX Future market:

Date (*yyyy-mm-dd*)				
2016-01-01	2016-02-08	2016-02-09	2016-03-25	2016-05-01

Late Opens

There are no days with late opens.

Time Zone

The MSCI Taiwan Index Futures contract in the SGX Future market trades in the `Asia/Singapore` time zone.

Asset Classes

Future Options

Future Option contracts give the buyer a window of opportunity to buy or sell the underlying Future contract at a specific price.

Future Options

Requesting Data

Introduction

Request Future Options data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Future Options dataset listing . To trade Future Options live, you can use our Future Options data feed or one of the brokerage data feeds . We currently only support American-style Options for Future Options.

Create Subscriptions

Before you can subscribe to a Future Option contract, you may configure the underlying volatility model and you must get the contract `Symbol` .

Configure the Underlying Futures Contract

In most cases, you should subscribe to the underlying Futures contract before you subscribe to a Futures Option contract. If you don't, LEAN automatically subscribes to the underlying Futures contract with the following settings:

Setting	Value
Fill forward	Same as the Option contract
Leverage	0
Extended Market Hours	Same as the Option contract

In this case, you still need the Futures contract `Symbol` to subscribe to Futures Option contracts. If you don't have access to it, create it.

```
self.future_contract_symbol = Symbol.CreateFuture(Futures.Indices.SP500EMini,
    Market.CME, datetime(2022, 6, 17))
```

PY

For more information about getting the `Symbol` of Futures contracts, see Create Subscriptions .

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Get Contract Symbols

To subscribe to a Future Option contract, you need the contract `Symbol` . You can get the contract `Symbol` from the `CreateOption` method or from the `OptionChainProvider` . If you use the `CreateOption` method, you need to provide the contract details.

```
self.option_contract_symbol = Symbol.CreateOption(self.future_contract_symbol,
    Market.CME, OptionStyle.American, OptionRight.Call, 3600, datetime(2022, 6, 17))
```

Another way to get a Future Option contract `Symbol` is to use the `OptionChainProvider` . The `GetOptionContractList` method of `OptionChainProvider` returns a list of `Symbol` objects that reference the available Option contracts for a given underlying Future contract on a given date. The `Symbol` you pass to the method can reference any of the following Futures contracts:

- The continuous Futures contract
- A contract in the Futures universe
- A contract that you added with `AddFutureContract`

To filter and select contracts that the `GetOptionContractList` method returns, you can use the following properties of each `Symbol` object:

Property	Description
`ID.Date`	The expiration date of the contract.
`ID.StrikePrice`	The strike price of the contract.
`ID.OptionRight`	The contract type. The `OptionRight` enumeration has the following members:
`ID.OptionStyle`	The contract style. The `OptionStyle` enumeration has the following members: We currently only support American-style Options for Future Options.

```
option_contract_symbols = self.OptionChainProvider.GetOptionContractList(self.future_contract_symbol,
self.Time)
expiry = min([symbol.ID.Date for symbol in option_contract_symbols])
filtered_symbols = [symbol for symbol in option_contract_symbols if symbol.ID.Date == expiry and
symbol.ID.OptionRight == OptionRight.Call]
self.option_contract_symbol = sorted(filtered_symbols, key=lambda symbol: symbol.ID.StrikePrice)[0]
```

Subscribe to Contracts

To create a Future Option contract subscription, pass the contract `Symbol` to the `AddFutureOptionContract` method. Save a reference to the contract `Symbol` so you can easily access the Option contract in the OptionChain that LEAN passes to the `OnData` method. To override the default pricing model of the Option, set a pricing model .

```
option = self.AddFutureOptionContract(self.option_contract_symbol)
option.PriceModel = OptionPriceModels.BjerksundStensland()
```

The `AddFutureOptionContract` method creates a subscription for a single Option contract and adds it to your **user-defined** universe. To create a dynamic universe of Future Option contracts, add a Future Options universe .

Warm Up Contract Prices

If you subscribe to a Future Option contract with `AddFutureOptionContract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
seeder = FuncSecuritySeeder(self.GetLastKnownPrices)
self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel, seeder, self))
```

PY

Supported Assets

To view the supported assets in the US Future Options dataset, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Future Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				
`Second`				
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

There is only one resolution option, so you don't need to pass a `resolution` argument to the `AddFutureOptionContract` method.

```
self.AddFutureOptionContract(self.option_contract_symbol, Resolution.Minute)
```

PY

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Future Options:

You don't need to pass a `Market` argument to the `AddFutureOptionContract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.AddFutureOptionContract(self.option_contract_symbol, fillForward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Future Options are already leveraged products, so you can't change their leverage.

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
self.AddFutureOptionContract(self.option_contract_symbol, extendedMarketHours=True)
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Remove Subscriptions

To remove a contract subscription that you created with `AddFutureOptionContract` , call the `RemoveOptionContract` method. This method is an alias for `RemoveSecurity` .

```
self.RemoveOptionContract(self.option_contract_symbol)
```

The `RemoveOptionContract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `AddFutureOptionContract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and the `Security` object for its underlying in any function, use the Option `Symbol` to access the value in the `Securities` object.

```
option = self.Securities[self.option_contract_symbol]
underlying = self.Securities[self.option_contract_symbol.Underlying]
underlying_price = underlying.Price
```

To get the Option payoff , call the `GetPayOff` method.

```
pay_off = option.GetPayOff(underlying_price)
```

To get the Option intrinsic value , call the `GetIntrinsicValue` method.

```
intrinsic_value = option.GetIntrinsicValue(underlying_price)
```
PY

To get the Option out-of-the-money amount , call the `OutOfTheMoneyAmount` method.

```
otm_amount = option.OutOfTheMoneyAmount(underlying_price)
```
PY

To check whether the Option can be automatic exercised, call the `IsAutoExercised` method.

```
is_auto_exercised = option.IsAutoExercised(underlying_price)
```
PY

Future Options

Handling Data

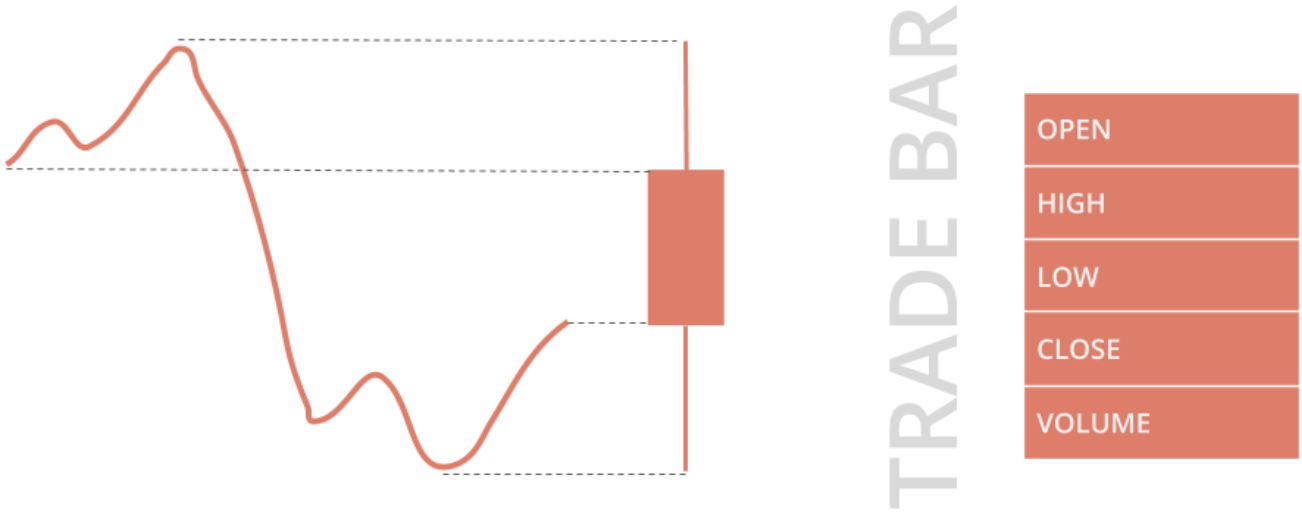
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the Futures Option contract ticker or `Symbol` , but we recommend you use the `Symbol` .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the Option contract `Symbol` . If the Option contract doesn't actively trade or you are in the same time step as when you added the Option contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your Option contract before you index the `Slice` with the Option contract `Symbol` .

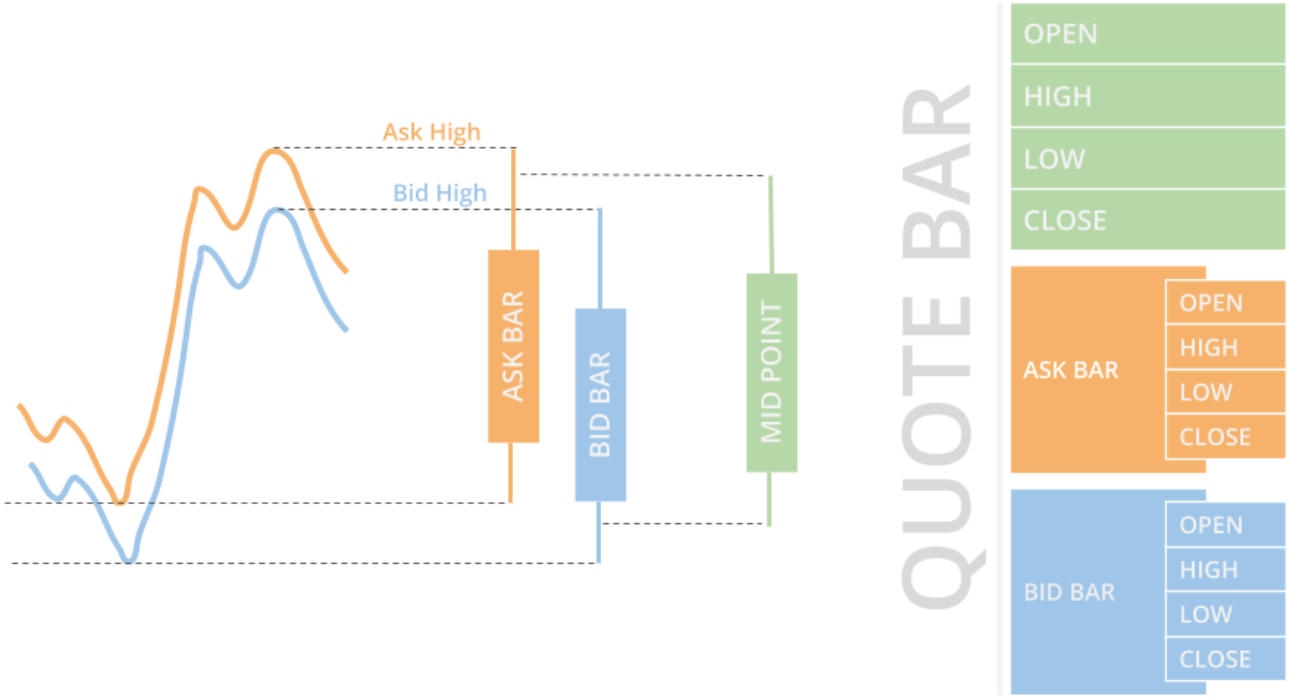
```
def OnData(self, slice: Slice) -> None:
    if self.option_contract_symbol in slice.Bars:
        trade_bar = slice.Bars[self.option_contract_symbol]
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        close_price = trade_bar.Close
```

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the Option contract `Symbol` . If the Option contract doesn't actively get quotes or you are in the same time step as when you added the Option contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your Option contract before you index the `Slice` with the Option contract `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.option_contract_symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.option_contract_symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. They have the following properties:

To get the `FuturesChain` , index the `FuturesChains` property of the `Slice` with the continuous contract `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.FuturesChains.get(self.future_contract_symbol.Canonical)
    if chain:
        contracts = chain.Contracts
```

You can also loop through the `FuturesChains` property to get each `FuturesChain` .

```
def OnData(self, slice: Slice) -> None:
    for continuous_contract_symbol, chain in slice.FuturesChains.items():
        contracts = chain.Contracts
```

Futures Contracts

`FuturesContract` objects represent the data of a single Futures contract in the market. They have the following properties:

To get the Futures contracts in the `Slice` , use the `Contracts` property of the `FuturesChain` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.FuturesChains.get(self.future_contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.future_contract_symbol)
        if contract:
            price = contract.LastPrice
```

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security. They have the

following properties:

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.option_contract_symbol.Canonical)
    if chain:
        contracts = chain.Contracts
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```
def OnData(self, slice: Slice) -> None:
    for canonical_fop_symbol, chain in slice.OptionChains.items():
        contracts = chain.Contracts
```

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. They have the following properties:

To get the Option contracts in the `Slice` , use the `Contracts` property of the `OptionChain` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.option_contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.option_contract_symbol)
        if contract:
            price = contract.Price
```

You can also iterate through the `FuturesChains` first.

```
def OnData(self, slice: Slice) -> None:
    for continuous_future_symbol, futures_chain in slice.FuturesChains.items():
        # Select a Future Contract and create its canonical FOP Symbol
        futures_contract = [contract for contract in futures_chain][0]
        canonical_fop_symbol = Symbol.CreateCanonicalOption(futures_contract.Symbol)
        option_chain = slice.OptionChains.get(canonical_fop_symbol)
        if option_chain:
            option_contract = option_chain.Contracts.get(self.option_contract_symbol)
            if option_contract:
                price = option_contract.Price
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `Greeks` and `ImpliedVolatility` members.

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.option_contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.option_contract_symbol)
        if contract:
            delta = contract.Greeks.Delta
            iv = contract.ImpliedVolatility
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `Greeks` member, the Greeks aren't calculated. However, if you invoke the `Greeks.Delta` member, LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `OpenInterest` property of the `Option` or `OptionContract` .

PY

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            open_interest = contract.OpenInterest
```

Future Options

Market Hours

Introduction

The Future Option markets have the same hours as the Futures market. For more information, see the supported contracts and the market hours of Future markets .

Asset Classes

Index

There are cash Indices and volatility Indices. The former is a hypothetical portfolio that represents a segment of the financial market and the latter shows the expected level of price fluctuation in an Index Option.

Requesting Data

Handling Data

Market Hours

Index

Requesting Data

Introduction

Request Index data in your algorithm to receive a feed of Index prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Cash Indices dataset listing . To trade live with Index data, you can use one of the brokerage data feeds .

Create Subscriptions

To create an Index subscription, in the `Initialize` method, call the `AddIndex` method. The `AddIndex` method returns an `Index` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the Index data in the `Slice` .

```
self.symbol = self.AddIndex("VIX").Symbol
```

PY

To view the supported assets in the US Cash Indices dataset, see the Supported Indices .

Resolutions

The following table shows the available resolutions and data formats for Index subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	
`Second`	✓			
`Minute`	✓			
`Hour`	✓			
`Daily`	✓			

The default resolution for Index subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddIndex` method.

```
self.symbol = self.AddIndex("VIX", Resolution.Daily).Symbol
```

PY

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for Indices is `Market.USA` , so you don't need to pass a `market` argument to the `AddIndex` method.

```
self.symbol = self.AddIndex("VIX", market=Market.USA).Symbol
```
PY

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.symbol = self.AddIndex("VIX", fillForward=False).Symbol
```
PY

Properties

The `AddIndex` method returns an `Index` object, which have the following properties:

Index

Handling Data

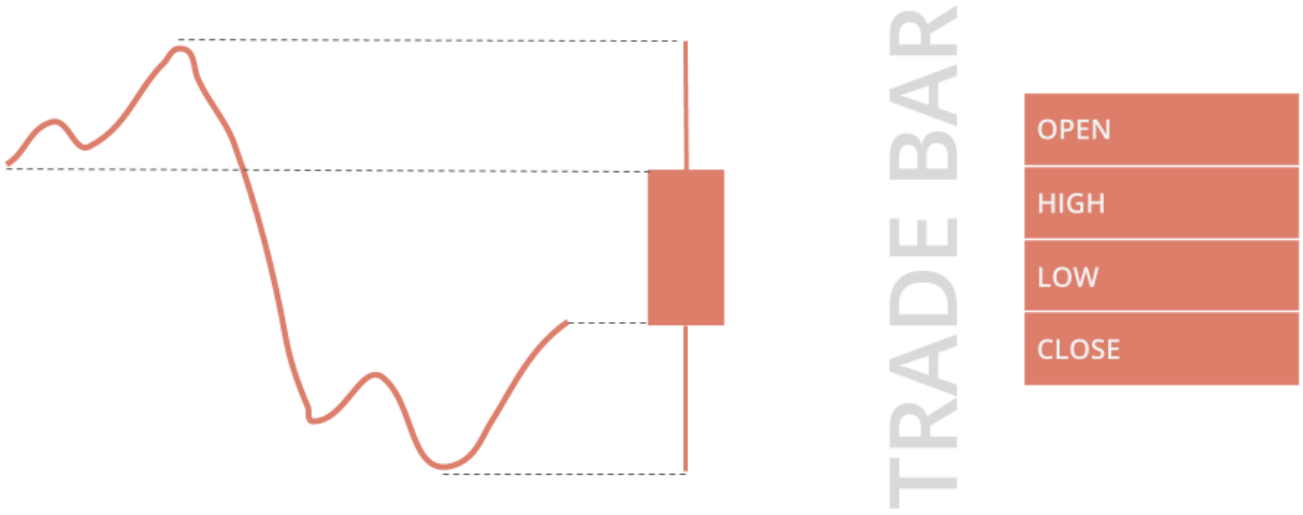
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `Ticks DataDictionary` is made up of `Tick` objects. To access individual data points in the dictionary, you can index the dictionary with the Index ticker or `Symbol` , but we recommend you use the `Symbol` .

Bars

You can't trade Indices, but `TradeBar` objects are bars that represent the open, high, low, and close of an Index price over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the Index `Symbol` . The `Slice` may not contain data for your `Symbol` at every time step. To avoid issues, check if the `Slice` contains data for your Index before you index the `Slice` with the Index `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
        value = trade_bar.Value
```

Ticks

`Tick` objects represent a price for the Index at a moment in time. `Tick` objects have the following properties:

Index ticks have a non-zero value for the `Price` property, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . The `Slice` may not contain data for your `Symbol` at every time step. To avoid issues, check if the `Slice` contains data for your Index before you index the `Slice` with the Index `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:

Introduction

This page shows the trading hours, holidays, and time zone of the CBOE Volatility Index market.

Pre-market Hours

The following table shows the pre-market hours for the CBOE Volatility Index market:

Weekday	Time (America/Chicago)
Monday	02:15:00 to 08:15:00
Tuesday	02:15:00 to 08:15:00
Wednesday	02:15:00 to 08:15:00
Thursday	02:15:00 to 08:15:00
Friday	02:15:00 to 08:15:00

Regular Trading Hours

The following table shows the regular trading hours for the CBOE Volatility Index market:

Weekday	Time (America/Chicago)
Monday	08:30:00 to 15:15:00
Tuesday	08:30:00 to 15:15:00
Wednesday	08:30:00 to 15:15:00
Thursday	08:30:00 to 15:15:00
Friday	08:30:00 to 15:15:00

Post-market Hours

The following table shows the post-market hours for the CBOE Volatility Index market:

Weekday	Time (America/Chicago)
Monday	15:15:00 to 16:00:00
Tuesday	15:15:00 to 16:00:00
Wednesday	15:15:00 to 16:00:00
Thursday	15:15:00 to 16:00:00
Friday	15:15:00 to 16:00:00

Holidays

The following table shows the dates of holidays for the CBOE Volatility Index market:

Date (*yyyy-mm-dd*)

Early Closes

There are no days with early closes.

Late Opens

There are no days with late opens.

Time Zone

The CBOE Volatility Index market trades in the `America/Chicago` time zone.

Asset Classes

Index Options

Index Options are a financial derivative that gives the holder the right (but not the obligation) to buy or sell the value of an underlying Index, such as the S&P 500 index, at the stated exercise price. No actual assets are bought or sold.

Index Options

Requesting Data

Introduction

Request Index Options data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Index Options dataset listing . To trade Index Options live, you can use one of the brokerage data feeds . We currently only support European-style Options for Index Options.

Create Subscriptions

Before you can subscribe to an Index Option contract, you must configure the underlying Index and get the contract `Symbol` .

Configure the Underlying Index

In most cases, you should subscribe to the underlying Index before you subscribe to an Index Option contract.

```
self.symbol = self.AddIndex("SPX").Symbol
```

If you subscribe to an Index Option contract but don't have a subscription to the underlying Index, LEAN automatically subscribes to the underlying Index and sets its fill forward property to match that of the Index Option contract. In this case, you still need the Index `Symbol` to subscribe to Index Option contracts. If you don't have access to it, create it.

```
self.symbol = Symbol.Create("SPX", SecurityType.Index, Market.USA)
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Get Contract Symbols

To get Index Option contract `Symbol` objects, call the `CreateOption` method or use the `OptionChainProvider` . If you use the `CreateOption` method, you need to know the specific contract details.

```
# Standard contracts
self.contract_symbol = Symbol.CreateOption(self.symbol, Market.USA,
    OptionStyle.European, OptionRight.Call, 3650, datetime(2022, 6, 17))

# Weekly contracts
self.weekly_contract_symbol = Symbol.CreateOption(self.symbol, "SPXW", Market.USA,
    OptionStyle.European, OptionRight.Call, 3650, datetime(2022, 6, 17))
```

Another way to get an Index Option contract `Symbol` is to use the `OptionChainProvider` . The `GetOptionContractList` method of `OptionChainProvider` returns a list of `Symbol` objects that reference the available Option contracts for a

given underlying Index on a given date. To filter and select contracts, you can use the following properties of each `Symbol` object:

Property	Description
`ID.Date`	The expiration date of the contract.
`ID.StrikePrice`	The strike price of the contract.
`ID.OptionRight`	The contract type. The `OptionRight` enumeration has the following members:
`ID.OptionStyle`	The contract style. The `OptionStyle` enumeration has the following members: We currently only support European-style Options for Index Options.

PY

```
# Standard contracts
self.canonical_symbol = Symbol.CreateCanonicalOption(self.symbol, Market.USA, "?SPX")
contract_symbols = self.OptionChainProvider.GetOptionContractList(self.canonical_symbol, self.Time)
expiry = min([symbol.ID.Date for symbol in contract_symbols])
filtered_symbols = [symbol for symbol in contract_symbols if symbol.ID.Date == expiry and
symbol.ID.OptionRight == OptionRight.Call]
self.contract_symbol = sorted(filtered_symbols, key=lambda symbol: symbol.ID.StrikePrice)[0]

# Weekly contracts
self.weekly_canonical_symbol = Symbol.CreateCanonicalOption(self.symbol, "SPXW", Market.USA, "?SPXW")
weekly_contract_symbols = self.OptionChainProvider.GetOptionContractList(self.weekly_canonical_symbol,
self.Time)
weekly_contract_symbols = [symbol for symbol in weekly_contract_symbols if OptionSymbol.IsWeekly(symbol)]
weekly_expiry = min([symbol.ID.Date for symbol in weekly_contract_symbols])
weekly_filtered_symbols = [symbol for symbol in weekly_contract_symbols if symbol.ID.Date == weekly_expiry
and symbol.ID.OptionRight == OptionRight.Call]
self.weekly_contract_symbol = sorted(weekly_filtered_symbols, key=lambda symbol: symbol.ID.StrikePrice)[0]
```

Subscribe to Contracts

To create an Index Option contract subscription, pass the contract `Symbol` to the `AddIndexOptionContract` method. Save a reference to the contract `Symbol` so you can easily access the contract in the OptionChain that LEAN passes to the `OnData` method. To override the default pricing model of the Option, set a pricing model .

PY

```
option = self.AddIndexOptionContract(self.contract_symbol)
option.PriceModel = OptionPriceModels.BlackScholes()
```

The `AddIndexOptionContract` method creates a subscription for a single Index Option contract and adds it to your **user-defined** universe. To create a dynamic universe of Index Option contracts, add an Index Option universe .

Warm Up Contract Prices

If you subscribe to an Index Option contract with `AddIndexOptionContract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
seeder = FuncSecuritySeeder(self.GetLastKnownPrices)
self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel, seeder, self))
```

Supported Assets

To view the supported assets in the US Index Options dataset, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Index Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				
`Second`				
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Index Option subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddIndexOptionContract` method.

```
self.AddIndexOptionContract(self.contract_symbol, Resolution.Hour)
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Index Options:

You don't need to pass a `Market` argument to the `AddIndexOptionContract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.AddIndexOptionContract(self.contract_symbol, fillForward=False)
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Options are

already leveraged products, so you can't change their leverage.

Remove Subscriptions

To remove a contract subscription that you created with `AddIndexOptionContract` , call the `RemoveOptionContract` method. This method is an alias for `RemoveSecurity` .

```
self.RemoveOptionContract(self.contract_symbol)
```

The `RemoveOptionContract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `AddIndexOptionContract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and the `Security` object for its underlying in any function, use the Option `Symbol` to access the value in the `Securities` object.

```
option = self.Securities[self.contract_symbol]
underlying = self.Securities[self.contract_symbol.Underlying]
underlying_price = underlying.Price
```

To get the Option payoff , call the `GetPayOff` method.

```
pay_off = option.GetPayOff(underlying_price)
```

To get the Option intrinsic value , call the `GetIntrinsicValue` method.

```
intrinsic_value = option.GetIntrinsicValue(underlying_price)
```

To get the Option out-of-the-money amount , call the `OutOfTheMoneyAmount` method.

```
otm_amount = option.OutOfTheMoneyAmount(underlying_price)
```

To check whether the Option can be automatic exercised, call the `IsAutoExercised` method.

```
is_auto_exercised = option.IsAutoExercised(underlying_price)
```

Handling Data

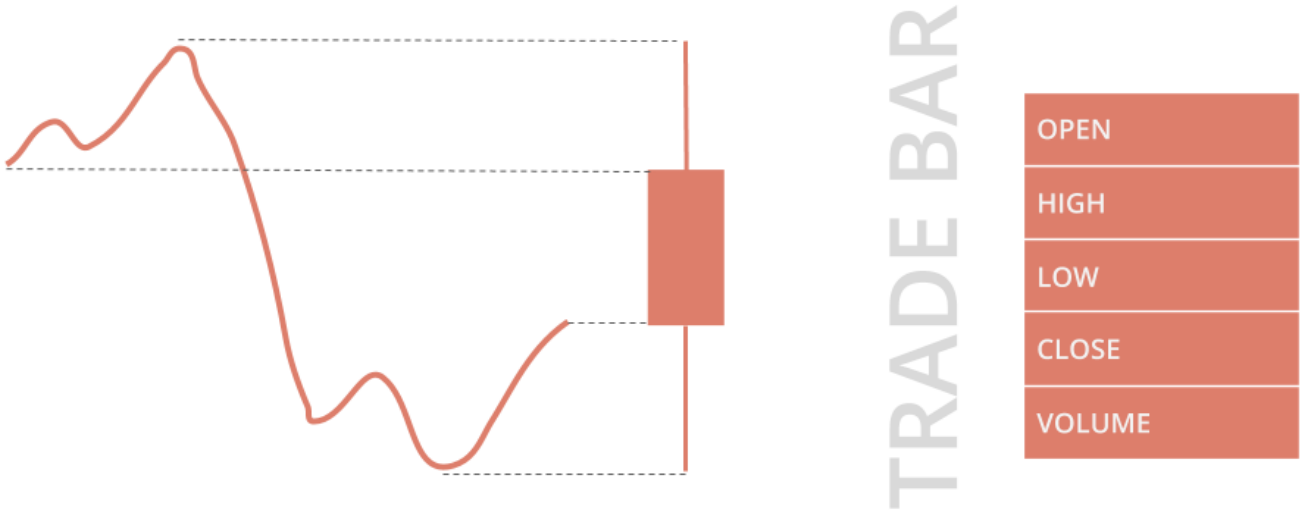
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `Symbol` , but we recommend you use the `Symbol` .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



`TradeBar` objects have the following properties:

To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

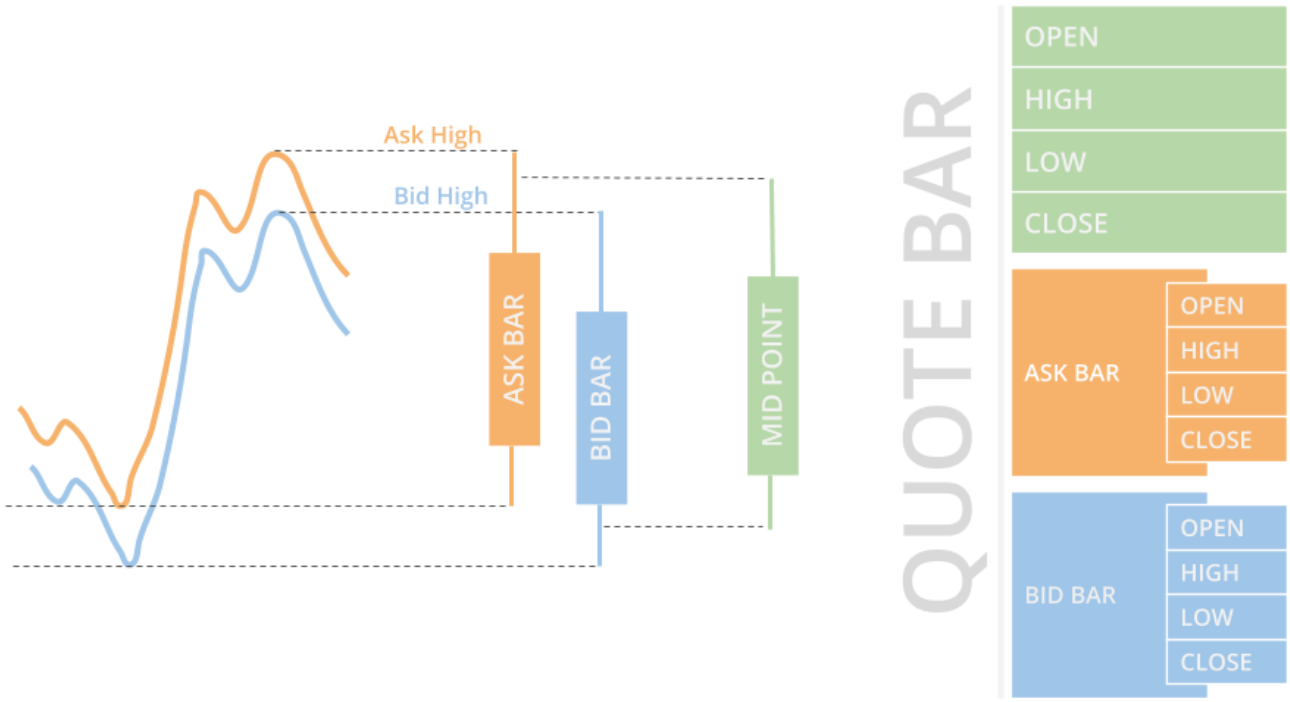
```
def OnData(self, slice: Slice) -> None:
    if self.contract_symbol in slice.Bars:
        trade_bar = slice.Bars[self.contract_symbol]
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        close_price = trade_bar.Close
```

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.contract_symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.contract_symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security. They have the following properties:

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contracts = chain.Contracts
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```
def OnData(self, slice: Slice) -> None:
    for canonical_symbol, chain in slice.OptionChains.items():
        contracts = chain.Contracts
```

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. They have the following properties:

To get the Option contracts in the `Slice` , use the `Contracts` property of the `OptionChain` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            price = contract.Price
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `Greeks` and `ImpliedVolatility` members.

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            delta = contract.Greeks.Delta
            iv = contract.ImpliedVolatility
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `Greeks` member, the Greeks aren't calculated. However, if you invoke the `Greeks.Delta` member, LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `OpenInterest` property of the `Option` or `OptionContract` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.contract_symbol.Canonical)
    if chain:
        contract = chain.Contracts.get(self.contract_symbol)
        if contract:
            open_interest = contract.OpenInterest
```

Market Hours

Introduction

This page shows the trading hours, holidays, and time zone of the US Index Option market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the US Index Option market:

Weekday	**Time (America/Chicago)**
Monday	08:30:00 to 15:20:00
Tuesday	08:30:00 to 15:20:00
Wednesday	08:30:00 to 15:20:00
Thursday	08:30:00 to 15:20:00
Friday	08:30:00 to 15:20:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the US Index Option market:

Early Closes

There are no days with early closes.

Late Opens

There are no days with late opens.

Time Zone

The CBOE Volatility Index Option contracts market trades in the `America/Chicago` time zone.

Asset Classes

CFD

A contract for difference (CFD) is a contract between a buyer and a seller that stipulates that the buyer must pay the seller the difference between the current value of an asset and its value at contract time.

CFD

Requesting Data

Introduction

Request Contract for Difference (CFD) data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the CFD dataset listing . To trade CFDs live, you can use our CFD data feed .

Create Subscriptions

To create a CFD subscription, in the `Initialize` method, call the `AddCfd` method. The `AddCfd` method returns a `Cfd` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
PY
self.symbol = self.AddCfd("XAUUSD").Symbol
```

To view the supported CFD contracts, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for CFD subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				✓
`Second`		✓		
`Minute`		✓		
`Hour`		✓		
`Daily`		✓		

The default resolution for CFD subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddCfd` method.

```
PY
self.symbol = self.AddCfd("XAUUSD", Resolution.Daily).Symbol
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for CFD contracts is `Market.Oanda` , so you don't need to pass a `market` argument to the `AddCfd` method.

```
self.symbol = self.AddCfd("XAUUSD", market=Market.Oanda).Symbol
```
PY

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
self.symbol = self.AddCfd("XAUUSD", fillForward=False).Symbol
```
PY

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The Oanda brokerage let's you use up to 50x leverage on margin accounts. To change the amount of leverage you can use for a CFD contract, pass a `leverage` argument to the `AddCfd` method.

```
self.symbol = self.AddCfd("XAUUSD", leverage=35).Symbol
```
PY

Properties

The `AddCfd` method returns a `Cfd` object, which have the following properties:

CFD

Handling Data

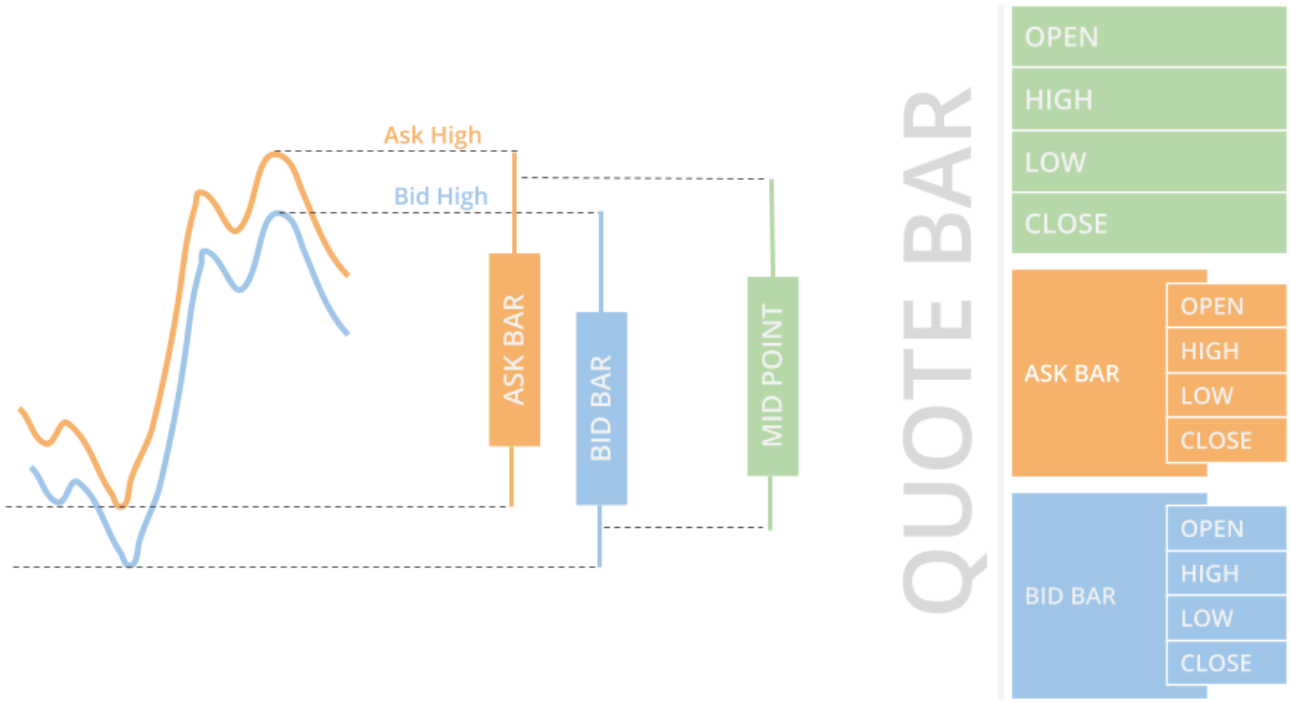
Introduction

LEAN passes the data you request to the `OnData` method so you can make trading decisions. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `QuoteBars DataDictionary` is made up of `QuoteBar` objects. To access individual data points in the dictionary, you can index the dictionary with the CFD ticker or `Symbol` , but we recommend you use the `Symbol` .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



`QuoteBar` objects have the following properties:

To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the CFD `Symbol` . If the CFD doesn't actively get quotes or you are in the same time step as when you added the CFD subscription, the `Slice` may

not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your CFD before you index the `Slice` with the CFD `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        ask_price = quote_bar.Ask.Close
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the CFD. A quote tick is an offer to buy or sell the CFD at a specific price. `Tick` objects have the following properties:

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the CFD doesn't actively trade or you are in the same time step as when you added the CFD subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your CFD before you index the `Slice` with the CFD `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            price = tick.Price
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `list[Tick]` objects.

```
def OnData(self, slice: Slice) -> None:
    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            price = tick.Price
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

CFD

Market Hours

Introduction

This page shows the trading hours, holidays, and time zone of the CFD market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the CFD market:

Weekday	Time (America/New York)
Sunday	17:00:00 to 24:00:00
Monday	00:00:00 to 24:00:00
Tuesday	00:00:00 to 24:00:00
Wednesday	00:00:00 to 24:00:00
Thursday	00:00:00 to 24:00:00
Friday	00:00:00 to 17:00:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the CFD market:

Date (*yyyy-mm-dd*)			
2022-12-25	2022-12-26	2023-01-01	2023-01-02

Early Closes

The following table shows the early closes for the CFD market:

Date (*yyyy-mm-dd*)	Time Of Market Close (America/New York)
2018-12-31	17:00:00

Late Opens

There are no days with late opens.

Time Zone

The CFD market trades in the following time zones:

- `America/Chicago`
- `America/New York`
- `Asia/Hong Kong`
- `Asia/Singapore`
- `Australia/Sydney`
- `Europe/Amsterdam`
- `Europe/Berlin`
- `Europe/London`
- `Europe/Paris`
- `Europe/Zurich`
- `UTC`

Portfolio

Portfolio

Key Concepts

Introduction

The `Portfolio` object provides information about the whole portfolio state.

Properties

The `Portfolio` object has the following properties:

```py
invested = self.Portfolio.Invested
value = self.Portfolio.TotalPortfolioValue
```

Cost Averaging Accounting

LEAN uses the cost averaging accounting method, which determines the cost of your holdings by taking a weighted average of all your purchase prices. For example, say you place the following buy orders:

1. Buy 10 ABC @ $10
2. Buy 5 ABC @ $11
3. Buy 20 ABC @ $14
4. Buy 3 ABC @ $9

In the preceding example, the average cost of your ABC position is (10*10 + 5*11 + 20*14 + 3*9) / (10 + 5 + 20 + 3) = 12.1579/share. In contrast, if you use the first-in, first-out (FIFO) accounting method, the cost of the first 10 shares is 10/share, not 12.1579/share.

To get the cost of your security holdings, use the `HoldingsCost` property of the SecurityHolding object . If you fill buy and sell orders, the holdings cost is the product of the holding quantity and the average price. For example, the following table shows how the average price and holdings cost changes with each buy and sell order order in a long position:

Order Quantity	Fill Price ($)	Holding Quantity	Average Price ($)	Holdings Cost ($)
2	10	2	(2 * 10) / 2 = 10	2 * 10 = 20
-1	11	1	(1 * 10) / 1 = 10	1 * 10 = 10
1	12	2	(1 * 10 + 1 * 12) / 2 = 11	2 * 11 = 22
-2	13	0	0	0 * 0 = 0

The following table shows how the average price and holdings cost changes with each buy and sell order order in a short position:

Order Quantity	Fill Price ($)	Holding Quantity	Average Price ($)	Holdings Cost ($)
-2	10	-2	(-2 * 10) / -2 = 10	-2 * 10 = -20
1	11	-1	(-1 * 10) / -1 = 10	-1 * 10 = -10
-1	12	-2	(-1 * 10 + (-1) * 12) / -2 = 11	-2 * 11 = -22
2	13	0	0	0 * 0 = 0

Note that when you decrease the position size without closing the trade, the average price doesn't change because the denominator and the coefficients in the numerator of its formula are scaled by the quotient of the current holding quantity and the previous holding quantity. For instance, if the last row in the preceding table had an order quantity 1, the holding quantity would be -1 and the average price would be

$$\frac{(-1 \cdot q) \cdot 10 + (-1 \cdot q) \cdot 12}{-2 \cdot q}$$

$$= \frac{(-1 \cdot \frac{-1}{-2}) \cdot 10 + (-1 \cdot \frac{-1}{-2}) \cdot 12}{-2 \cdot \frac{-1}{-2}}$$

$$= \frac{\frac{-1}{2} \cdot 10 + \frac{-1}{2} \cdot 12}{-1}$$

$$= \frac{-5-6}{-1} = 11$$

Long and Short Holdings

You can identify a position as long- or short-biased based on the sign of the holding quantity. Long positions have a positive quantity and short positions have a negative quantity.

Buying Power

To get the maximum buying power in your account currency you can use for a given `Symbol` and order direction, call the `GetBuyingPower` method.

```
available_buying_power = self.Portfolio.GetBuyingPower(self.symbol, OrderDirection.Buy)
```

PY

For more information about buying power, see Buying Power .

Portfolio

Holdings

Introduction

The `Portfolio` is a dictionary where the key is a `Symbol` and the value is a `SecurityHolding` .

```
security_holding = self.Portfolio["SPY"]
```

PY

Properties

`SecurityHolding` objects have the following properties:

```
security_holding = self.Portfolio["SPY"]
quantity = security_holding.Quantity
invested = security_holding.Invested
```

PY

Get Total Close Profit

To get the profit of a position holding if you closed the position, call the `TotalCloseProfit` method. The value this method returns is denominated in your account currency and accounts for order fees.

```
profit = self.Portfolio["SPY"].TotalCloseProfit()
```

PY

The `TotalCloseProfit` method accepts the following optional arguments:

Argument	Data Type	Description	Default Value
includeFees	bool	Whether to reduce the profit based on the estimated fee from the fee model .	True
exitPrice	float/NoneType	A hypothetical exit price to use for the profit calculation. If you don't provide a value, it uses the bid price for sell orders or the ask price for buy orders.	None
entryPrice	float/NoneType	A hypothetical exit price to use for the profit calculation. If you don't provide a value, it uses the average price of the SecurityHolding .	None
quantity	float/NoneType	The quantity to liquidate. If you don't provide a value, it uses the quantity of the SecurityHolding .	None

LEAN uses this method to define the UnrealizedProfit property.

Get Quantity Value

To get the value of a security at any quantity, call the GetQuantityValue method. The value this method returns is denominated in your account currency.

```
# Get the quantity value at the current price
value_at_current_price = self.Portfolio["SPY"].GetQuantityValue(100)

# Get the quantity value at a specific price
value_at_specific_price = self.Portfolio["SPY"].GetQuantityValue(100, price=30)
```

Portfolio

Cashbook

Introduction

The `CashBook` is a dictionary where the keys are currency tickers and the values are `Cash` objects. The `Cash` objects track the amount of each currency in the portfolio. As you buy and sell securities, LEAN credits and debits the `Cash` objects to reflect your cash holdings.

Account Currency

The default account currency is USD, but you can change it. All of the properties of the Portfolio object that return a currency value denominate the currency value in your account currency. Depending on your account currency and security subscriptions, LEAN may add internal security subscriptions to calculate the `ValueInAccountCurrency` . For example, if you only add BTCETH to your algorithm and set the account currency to USDT, LEAN adds BTCUSDT and ETHUSDT as internal feeds.

To get your account currency, use the `AccountCurrency` property.

```
account_currency = self.AccountCurrency
```

To set your account currency, in the `Initialize` method, call the `SetAccountCurrency` method. You can only set the account currency once. LEAN ignores each additional call to `SetAccountCurrency` .

```
self.SetAccountCurrency("EUR")
```

Settled vs Unsettled Cash

The `Portfolio` has two independent cashbooks. The `CashBook` tracks settled cash and the `UnsettledCashBook` tracks unsettled cash, which you can't spend. If you trade with a margin account, trades settle immediately so LEAN credits and debits the `CashBook` at the time of the trade. In some cases, transactions can take time to settle. For example, Equity trades in a cash account settle in T+3. Therefore, if you sell shares of stock on Monday, the transaction settles on Thursday. In contrast, Option trades settle in T+1.

```
settled_cash_book = self.Portfolio.CashBook
unsettled_cash_book = self.Portfolio.UnsettledCashBook
```

Track Cash Balances

To get the balance of a currency in the cash book, use the `Amount` property.

```
usd = self.Portfolio.CashBook["USD"].Amount
btc = self.Portfolio.CashBook["BTC"].Amount
```

To get the value of a currency in the cash book, denominated in your account currency, use the `ValueInAccountCurrency` property.

```
eth_value = self.Portfolio.CashBook["ETH"].ValueInAccountCurrency
```

Deposits and Withdraws

In backtests, you can add and remove cash from the cash book. To add or remove cash, call the `AddAmount` method.

```
new_usd_balance = self.Portfolio.CashBook["USD"].AddAmount(100)
new_btc_balance = self.Portfolio.CashBook["BTC"].AddAmount(-1.5)
```

In live trading, add and withdraw cash through your brokerage account. If you adjust the cash balances in your algorithm with the `AddAmount` method, the cash balance in your algorithm will be out of sync with the cash balance in your brokerage account.

Currency Symbols

A currency symbol is a graphic that represents the currency name. For example, $ is for dollars, € for euros, and ฿ for Bitcoin. To get the symbol of a currency in the cash book, use `CurrencySymbol` property.

```
usd_symbol = self.Portfolio.CashBook["USD"].CurrencySymbol
```

Conversion Rates

To get the conversion rate for a currency in the cashbook to your account currency, use the `ConversionRate` property.

```
eur_conversion_rate = self.Portfolio.CashBook["EUR"].ConversionRate
```

Universes

Universes

Key Concepts

Introduction

Universe selection is the process of selecting a basket of assets you may trade. Dynamic universe selection increase diversification and decrease selection bias in your algorithm.

How Universe Selection Works

When you add a universe to your algorithm, LEAN sends a large dataset into a filter function you define. Your filter function needs to return a list of `Symbol` objects. LEAN automatically subscribes to these new symbols and adds them to your algorithm. Your algorithm can do almost anything inside your filter functions, but the goal should be to narrow down the set of securities to the securities that are most applicable for your algorithm.

Security Changed Events

When your universe adds and removes assets, LEAN notifies your algorithm through the `OnSecuritiesChanged` event handler. The event handler receives a `SecurityChanges` object, which contains references to the added and removed securities. To access the added securities, check the `changes.AddedSecurities` property. To access the removed securities, check the `changes.RemovedSecurities` property.

```py
def OnSecuritiesChanged(self, changes: SecurityChanges) -> None:
    for security in changes.AddedSecurities:
        self.Debug(f"{self.Time}: Added {security.Symbol}")

    for security in changes.RemovedSecurities:
        self.Debug(f"{self.Time}: Removed {security.Symbol}")

        if security.Invested:
            self.Liquidate(security.Symbol, "Removed from Universe")
```

The preceding example liquidates securities that leave the universe. In this case, LEAN creates a market on open order and frees up buying power when the market opens.

A convenient way to track the securities that are currently in the universe is to maintain a `self.securities` list.

```
# In Initialize
self.securities = []

def OnSecuritiesChanged(self, changes: SecurityChanges) -> None:
    for security in changes.RemovedSecurities:
        if security in self.securities:
            self.securities.remove(security)

    self.securities.extend(changes.AddedSecurities)
```

If you need to save data or create objects for each security in the universe, maintain a dictionary of custom `SymbolData` objects. This technique is useful if you want to track stop loss levels or add indicators for each asset in the universe.

```
# In Initialize
self.symbol_data_by_symbol = {}

def OnSecuritiesChanged(self, changes: SecurityChanges) -> None:
    for security in changes.AddedSecurities:
        self.symbol_data_by_symbol[security.Symbol] = SymbolData() # You need to define this class

    for security in changes.RemovedSecurities:
        self.symbol_data_by_symbol.pop(security.Symbol, None)
```

Select Current Constituents

If you don't want to make any changes to the current universe, return `Universe.Unchanged` from your filter functions.

```
class MyUniverseAlgorithm(QCAlgorithm):
     def Initialize(self) -> None:
         self.AddUniverse(self.MyCoarseFilterFunction)

    def MyCoarseFilterFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
         return Universe.Unchanged
```

Universe Manager

The universe manager tracks all the universes in your algorithm. If you add multiple universe, you can access the constituents of each individual universe. To access the constituents of a universe in a multi-universe algorithm, save references to each universe when you add them.

```
# In Initialize
self.universe = self.AddUniverse(self.MyCoarseFilterFunction)

# In OnData
universe_members = self.UniverseManager[self.universe.Configuration.Symbol].Members
for kvp in universe_members:
    symbol = kvp.Key
    security = kvp.Value
```

Active Securities

The `ActiveSecurities` property of the algorithm class contains all of the assets currently in your universe. It is a dictionary where the key is a `Symbol` and the value is a `Security` . When you remove an asset from a universe, LEAN usually removes the security from the `ActiveSecurities` collection and removes the security subscription. However, it

won't remove the security in any of the following situations:

- You own the security.
- You have an open order for the security.
- The security wasn't in the universe long enough to meet the `MinimumTimeInUniverse` setting.

When LEAN removes the security, the `Security` object remains in the `Securities` collection for record-keeping purposes, like tracking fees and trading volume.

Derivative Universes

In a regular universe, you select a basket of assets from the entire universe of securities. In a derivative universe, you select a basket of contracts for an underlying asset. The following derivative universes are available:

- Equity Options
- Futures
- Future Options
- Index Options

Universes

Settings

Introduction

Universe settings and security initializers enable you to configure some properties of the securities in a universe.

Properties

The universe settings of your algorithm configure some properties of the universe constituents. The following table describes the properties of the `UniverseSettings` object:

Property: `ExtendedMarketHours` Should assets also feed extended market hours? You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily resolution, the daily bars only reflect the regular trading hours. Data Type: `bool` | Default Value: `False`
Property: `FillForward` Should asset data fill forward? Data Type: `bool` | Default Value: `True`
Property: `MinimumTimeInUniverse` What's the minimum time assets should be in the universe? Data Type: `timedelta` | Default Value: `timedelta(1)`
Property: `Resolution` What resolution should assets use? Data Type: `Resolution` | Default Value: `Resolution.Minute`

Property: `ContractDepthOffset` What offset from the current front month should be used for continuous Future contracts ? 0 uses the front month and 1 uses the back month contract. This setting is only available for Future assets. Data Type: `int` | Default Value: `0`
Property: `DataMappingMode` How should continuous Future contracts be mapped? This setting is only available for Future assets. Data Type: `DataMappingMode` | Default Value: `DataMappingMode.OpenInterest`
Property: `DataNormalizationMode` How should historical prices be adjusted? This setting is only available for Equity and Futures assets. Data Type: `DataNormalizationMode` | Default Value: `DataNormalizationMode.Adjusted`
Property: `Leverage` What leverage should assets use in the universe? This setting is not available for derivative assets. Data Type: `float` | Default Value: `Security.NullLeverage`

To set the `UniverseSettings` , update the preceding properties in the `Initialize` method before you add the "universe" These settings are globals, so they apply to all universes you create.

```py
# Request second resolution data. This will be slow!
self.UniverseSettings.Resolution = Resolution.Second
self.AddUniverse(self.MyCoarseFilterFunction)
```

Configure Universe Securities

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `Initialize` method, call the `SetSecurityInitializer` method and then define the security initializer.

```
#In Initialize
self.SetSecurityInitializer(self.CustomSecurityInitializer)

def CustomSecurityInitializer(self, security: Security) -> None:
    # Disable trading fees
    security.SetFeeModel(ConstantFeeModel(0, "USD"))
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```
self.SetSecurityInitializer(lambda security: security.SetFeeModel(ConstantFeeModel(0, "USD")))
```

In some cases, you may want to trade a security in the same time loop that you create the security subscription. To avoid errors, use a security initializer to set the market price of each security to the last known price. The `GetLastKnownPrices` method seeds the security price by gathering the security data over the last 3 days. If there is no data during this period, the security price remains at 0.

```
seeder = FuncSecuritySeeder(self.GetLastKnownPrices)
self.SetSecurityInitializer(lambda security: seeder.SeedSecurity(security))
```

If you call the `SetSecurityInitializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, create a custom `BrokerageModelSecurityInitializer` .

```
PY
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetFeeModel(ConstantFeeModel(0, "USD"))
```

To set a seeder function without overwriting the reality models of the brokerage, use the standard `BrokerageModelSecurityInitializer`.

```
PY
self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))
```

Selection Frequency

Most universes run on a daily basis, but some can select assets at different frequencies.

Universes

Equity

Introduction

There are several ways to create an Equities universe. You can select a universe based on `CoarseFundamental` data or the constituents of an ETF, and then you can further filter your universe down with corporate fundamentals. The following sections explain each of these techniques in detail.

Coarse Universe Selection

A coarse universe enables you pick a set of stocks based on their trading volume, price, or whether they have fundamental data. To add a coarse universe, in the `Initialize` method, pass a filter function to the `AddUniverse` method. The coarse filter function receives a list of `CoarseFundamental` objects and must return a list of `Symbol` objects. The `Symbol` objects you return from the function are the constituents of the universe and LEAN automatically creates subscriptions for them. Don't call `AddEquity` in the filter function.

```
PY
class MyCoarseUniverseAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.AddUniverse(self.CoarseFilterFunction)

    def CoarseFilterFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        sorted_by_dollar_volume = sorted(coarse, key=lambda x: x.DollarVolume, reverse=True)
        return [c.Symbol for c in sorted_by_dollar_volume[:100]]
```

`CoarseFundamental` objects have the following attributes:

The total number of stocks in the US Equity Security Master dataset is 30,000 but your coarse filter function won't receive all of these at one time because the US Equity Security Master dataset is free of survivorship bias and some of the securities have delisted over time. The number of securities that are passed into your coarse filter function depends on the date of your algorithm. Currently, there are about 10,000 securities that LEAN passes into your coarse filter function.

Dollar Volume Selection

A dollar volume universe enables you pick the most liquid stocks in the market with just one line of code. To add a dollar volume universe, call the `Universe.DollarVolume.Top` helper method and pass the result to the `AddUniverse` method.

```
PY
// Add the 50 stocks with the highest dollar volume
self.AddUniverse(self.Universe.DollarVolume.Top(50))
```

ETF Constituents Selection

An ETF constituents universe lets you select a universe of securities in an ETF. The US ETF Constituents dataset

includes 2,650 US ETFs you can use to create your universe. To add an ETF Constituents universe, call the `Universe.ETF` method.

```
class ETFConstituentsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.AddUniverse(self.Universe.ETF("SPY", Market.USA, self.UniverseSettings))
```

The following table describes the `ETF` method arguments:

Argument: `etfTicker` The ETF ticker. To view the supported ETFs in the US ETF Constituents dataset, see Supported ETFs . Data Type: `str` | Default Value: None
Argument: `market` The market of the ETF. If you don't provide an argument, it uses the default Equity market of the brokerage model . Data Type: `str` | Default Value: None
Argument: `universeSettings` The universe settings . If you don't provide an argument, it uses the algorithm `UniverseSettings` . Data Type: `UniverseSettings` | Default Value: None
Argument: `universeFilterFunc` A function to select some of the ETF constituents for the universe. If you don't provide an argument, it selects all of the constituents. Data Type: `Callable[[List[ETFConstituentData]], List[Symbol]]` | Default Value: `None`

To select a subset of the ETF constituents, provide a `universeFilterFunc` argument. The filter function receives `ETFConstituentData` objects, which represent one of the ETF constituents. `ETFConstituentsData` objects have the following attributes:

```py
class ETFConstituentsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        universe = self.Universe.ETF("SPY", Market.USA, self.UniverseSettings, self.ETFConstituentsFilter)
        self.AddUniverse(universe)

    def ETFConstituentsFilter(self, constituents: List[ETFConstituentData]) -> List[Symbol]:
        # Get the 10 securities with the largest weight in the index
        selected = sorted([c for c in constituents if c.Weight],
            key=lambda c: c.Weight, reverse=True)[:10]
        return [c.Symbol for c in selected]
```

Fundamentals Selection

A fundamental universe lets you select stocks based on corporate fundamental data. This data is powered by Morningstar® and includes approximately 5,000 tickers with 900 properties each. Due to the sheer volume of information, fundamental selection is performed on the output of another universe filter. Think of this process as a 2-stage filter. An initial filter function selects a set of stocks and then a fine fundamental filter function selects a subset of those stocks.

QuantConnect Coarse and Fine Universe Selection

To add a fundamental universe, in the `Initialize` method, pass two filter functions to the `AddUniverse` method. The first filter function can be a coarse universe filter , dollar volume filter , or an ETF constituents filter . The second filter function receives a list of `FineFundamental` objects and must return a list of `Symbol` objects. The list of `FineFundamental` objects contains a subset of the `Symbol` objects that the first filter function returned. The `Symbol` objects you return from the second function are the constituents of the fundamental universe and LEAN automatically creates subscriptions for them. Don't call `AddEquity` in the filter function.

> **Tip:** Only 5,000 assets have fundamental data. If your first filter function receives `CoarseFundamental` data, you should only select assets that have a true value for their `HasFundamentalData` property.

```py
class MyUniverseAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.AddUniverse(self.CoarseFilterFunction, self.FineFundamentalFunction)

    def CoarseFilterFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        # In addition to further coarse universe selection, ensure the security has fundamental data
        return [c.Symbol for c in coarse if c.HasFundamentalData]

    def FineFundamentalFunction(self, fine: List[FineFundamental]) -> List[Symbol]:
        # Return a list of Symbols
```

`FineFundamental` objects have the following attributes:

Example

The simplest example of accessing the fundamental object would be harnessing the iconic PE ratio for a stock. This is a ratio of the price it commands to the earnings of a stock. The lower the PE ratio for a stock, the more affordable it appears.

```
PY
# In Initialize:
self.AddUniverse(self.CoarseSelectionFunction, self.FineSelectionFunction)

def CoarseSelectionFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    sortedByDollarVolume = sorted(coarse, key=lambda x: x.DollarVolume, reverse=True)
    filtered = [x.Symbol for x in sortedByDollarVolume if x.HasFundamentalData]
    return filtered[:50]

def FineSelectionFunction(self, fine: List[FineFundamental]) -> List[Symbol]:
    sortedByPeRatio = sorted(fine, key=lambda x: x.ValuationRatios.PERatio, reverse=False)
    return [x.Symbol for x in sortedByPeRatio[:10]]
```

Asset Categories

In addition to valuation ratios, the US Fundamental Data from Morningstar has many other data point attributes, including over 200 different categorization fields for each US stock. Morningstar groups these fields into sectors, industry groups, and industries.

Sectors are large super categories of data. To get the sector of a stock, use the `MorningstarSectorCode` property.

```
PY
tech = [x for x in fine if x.AssetClassification.MorningstarSectorCode ==
MorningstarSectorCode.Technology]
```

Industry groups are clusters of related industries that tie together. To get the industry group of a stock, use the `MorningstarIndustryGroupCode` property.

```
PY
ag = [x for x in fine if x.AssetClassification.MorningstarIndustryGroupCode ==
MorningstarIndustryGroupCode.Agriculture]
```

Industries are the finest level of classification available. They are the individual industries according to the Morningstar classification system. To get the industry of a stock, use the `MorningstarIndustryCode` .

```
PY
coal = [x for x in fine if x.AssetClassification.MorningstarIndustryCode == MorningstarSectorCode.Coal]
```

Practical Limitations

Like coarse universes, fine universes allow you to select an unlimited universe of assets to analyze. Each asset in the universe consumes approximately 5MB of RAM, so you may quickly run out of memory if your universe filter selects many assets. If you backtest your algorithms in the Algorithm Lab, familiarize yourself with the RAM capacity of your backtesting and live trading nodes . To keep your algorithm fast and efficient, only subscribe to the assets you need.

Selection Frequency

Equity universes run on a daily basis.

Live Trading Considerations

The live data for coarse and fine universe selection arrives at 7 AM Eastern Time (ET), so coarse and fine universe selection runs for live algorithms between 7 and 8 AM ET. This timing allows you to place trades before the market opens. Don't schedule anything for midnight because the universe selection data isn't ready yet.

Examples

The following examples are typical filter functions you may want.

Example 1: Take 500 stocks that are worth more than 10*andhavemorethan*10M daily trading volume

The most common use case is to select a lot of liquid stocks. With a coarse universe filter, this is simple and fast. The following example selects the top most liquid 500 stocks over $10 per share.

```
PY
def CoarseFilterFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    sortedByDollarVolume = sorted(coarse, key=lambda x: x.DollarVolume, reverse=True)
    filtered = [ x.Symbol for x in sortedByDollarVolume
                 if x.Price > 10 and x.DollarVolume > 10000000 ]
    return filtered[:500]
```

Example 2: Take 10 stocks above their 200-Day EMA and have more than $1B daily trading volume

Another common request is to filter the universe by a technical indicator, such as only picking stocks above their 200-day EMA. The `CoarseFundamental` object has adjusted price and volume information, so you can do any price-related analysis.

```
PY
# setup state storage in initialize method
self.stateData = { }

def CoarseFilterFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    # We are going to use a dictionary to refer the object that will keep the moving averages
    for c in coarse:
        if c.Symbol not in self.stateData:
            self.stateData[c.Symbol] = SelectionData(c.Symbol, 200)

        # Updates the SymbolData object with current EOD price
        avg = self.stateData[c.Symbol]
        avg.update(c.EndTime, c.AdjustedPrice, c.DollarVolume)

    # Filter the values of the dict to those above EMA and more than $1B vol.
    values = [x for x in self.stateData.values() if x.is_above_ema and x.volume > 1000000000]

    # sort by the largest in volume.
    values.sort(key=lambda x: x.volume, reverse=True)

    # we need to return only the symbol objects
    return [ x.symbol for x in values[:10] ]
```

In this example, the `SelectionData` class group variables for the universe selection and updates the indicator of each asset. We highly recommend you follow this pattern to keep your algorithm tidy and bug free. The following snippet shows an example implementation of the `SelectionData` class, but you can make this whatever you need to store your custom universe filters.

```
class SelectionData(object):
    def __init__(self, symbol, period):
        self.symbol = symbol
        self.ema = ExponentialMovingAverage(period)
        self.is_above_ema = False
        self.volume = 0

    def update(self, time, price, volume):
        self.volume = volume
        if self.ema.Update(time, price):
            self.is_above_ema = price > ema
```

Note that the preceding `SelectionData` class uses a manual EMA indicator instead of the automatic version . For more information about universes that select assets based on indicators, see Indicator Universes .

Example 3: Take 10 stocks that are the furthest above their 10-day SMA of volume

The process to get the 10-day SMA stock volume is the same process as in Example 2. First, you should define a `SelectionData` class that performs the averaging. For this example, the following class will serve this purpose:

```
class SelectionData(object):
    def __init__(self, symbol, period):
        self.symbol = symbol
        self.volume = 0
        self.volume_ratio = 0
        self.sma = SimpleMovingAverage(period)

    def update(self, time, price, volume):
        self.volume = volume
        if self.sma.Update(time, volume):
            # get ratio of this volume bar vs previous 10 before it.
            self.volume_ratio = volume / self.sma.Current.Value
```

This class tracks the ratio of today's volume relative to historical volumes. You can use this ratio to select assets that are above their 10-day simple moving average and sort the results by the ones that have had the biggest jump since yesterday.

```
def CoarseFilterFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    for c in coarse:
        if c.Symbol not in self.stateData:
            self.stateData[c.Symbol] = SelectionData(c.Symbol, 10)
        avg = self.stateData[c.Symbol]
        avg.update(c.EndTime, c.AdjustedPrice, c.DollarVolume)

    # filter the values of selectionData(sd) above SMA
    values = [sd for sd in self.stateData.values() if sd.volume > sd.sma.Current.Value and sd.volume_ratio
> 0]

    # sort sd by the largest % jump in volume.
    values.sort(key=lambda sd: sd.volume_ratio, reverse=True)

    # return the top 10 symbol objects
    return [ sd.symbol for sd in values[:10] ]
```

Example 4: Take the top 10 "fastest moving" stocks with a 50-Day EMA > 200 Day EMA

You can construct complex universe filters with the `SelectionData` helper class pattern. To view a full example of this algorithm, see the EmaCrossUniverseSelectionAlgorithm in the LEAN GitHub repository or take the related Boot Camp lesson .

Universes

Equity Options

Introduction

An Equity Options universe lets you select a basket of contracts for a single Option. LEAN models Option subscriptions as a universe of Option contracts.

Create Universes

To add a universe of Equity Option contracts, in the `Initialize` method, call the `AddOption` method. This method returns an `Option` object, which contains the canonical `Symbol` . You can't trade with the canonical Option `Symbol` , but save a reference to it so you can easily access the Option contracts in the OptionChain that LEAN passes to the `OnData` method.

```
PY
option = self.AddOption("SPY")
self.symbol = option.Symbol
```

The following table describes the `AddOption` method arguments:

Argument	Data Type	Description	Default Value
`ticker`	`str`	The underlying Equity ticker. To view the supported underlying Equity tickers, see Supported Assets .	
`resolution`	`Resolution/NoneType`	The resolution of the market data. To view the supported resolutions, see Resolutions . The Equity resolution must be less than or equal to the Equity Option resolution. For example, if you set the Equity resolution to minute, then you must set the Equity Option resolution to minute, hour, or daily.	`None`
`market`	`str`	The underlying Equity market.	`None`
`fillForward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.	`True`
`leverage`	`float`	The leverage for this Equity.	`Security.NullLeverage`
`extendedMarketHours`	`bool`	A flag that signals if LEAN should send data during pre- and post-market trading hours.	`False`

If you add an Equity Option universe but don't have a subscription to the underlying Equity, LEAN automatically subscribes to the underlying Equity with the following settings:

Setting	Value
Fill forward	Same as the Option universe
Leverage	0
Extended Market Hours	Same as the Option universe
Data Normalization	`DataNormalizationMode.Raw`

If you already have a subscription to the underlying Equity but it's not `Raw` data normalization, LEAN automatically changes it to `Raw` .

To override the default pricing model of the Option, set a pricing model .

```
option.PriceModel = OptionPriceModels.CrankNicolsonFD()
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Filter Contracts

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 31 days

To adjust the universe of contracts, set a filter. The filter usually runs at every time step in your algorithm. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

To set a contract filter, in the `Initialize` method, call the `SetFilter` method of the `Option` object. The following table describes the available filter techniques:

Method	Description
`SetFilter(minStrike: int, maxStrike: int)`	Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302*andtherearestrikesatevery*5. If you set `minStrike` to -1 and `maxStrike` to 1, LEAN selects the contracts that have a strike of 300*or*305.
`SetFilter(minExpiry: timedelta, maxExpiry: timedelta)`	Selects the contracts that expire within the range you set.
`SetFilter(minStrike: int, maxStrike: int, minExpiry: timedelta, maxExpiry: timedelta)`	Selects the contracts that expire and have a strike within the range you set.
`SetFilter(universeFunc: Callable[[OptionFilterUniverse], OptionFilterUniverse])`	Selects the contracts that a function selects.

```
# Select contracts that have a strike price within 1 strike level above and below the underlying price
option.SetFilter(minStrike=-1, maxStrike=1)

# Select contracts that expire within 30 days
option.SetFilter(minExpiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select contracts that have a strike price within 1 strike level and expire within 30 days
option.SetFilter(minStrike=-1, maxStrike=1, minExpiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select call contracts
option.SetFilter(lambda option_filter_universe: option_filter_universe.CallsOnly())
```

The following table describes the filter methods of the `OptionFilterUniverse` class:

Method	Description
`Strikes(minStrike: int, maxStrike: int)`	Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price
`CallsOnly()`	Selects call contracts
`PutsOnly()`	Selects put contracts
`StandardsOnly()`	Selects standard contracts
`IncludeWeeklys()`	Selects non-standard weeklys contracts
`WeeklysOnly()`	Selects weekly contracts
`FrontMonth()`	Selects the front month contract
`BackMonths()`	Selects the non-front month contracts
`BackMonth()`	Selects the back month contracts
`Expiration(minExpiry: timedelta, maxExpiry: timedelta)`	Selects contracts that expire within a range of dates relative to the current day
`Expiration(minExpiryDays: int, maxExpiryDays: int)`	Selects contracts that expire within a range of dates relative to the current day
`Contracts(contracts: List[Symbol])`	Selects a list of contracts
`Contracts(contractSelector: Callable[[List[Symbol]], List[Symbol]])`	Selects contracts that a selector function selects
`OnlyApplyFilterAtMarketOpen()`	Instructs the engine to only filter contracts on the first time step of each market day

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```py
# Example 1: Select the front month call contracts
option.SetFilter(lambda option_filter_universe: option_filter_universe.CallsOnly().FrontMonth())

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.SetFilter(lambda option_filter_universe: option_filter_universe.IncludeWeeklys().Strikes(-20,
20).Expiration(0, 90))
```

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```
# In Initialize
option.SetFilter(self.contract_selector)

def contract_selector(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    symbols = option_filter_universe.PutsOnly()
    strike = min([symbol.ID.StrikePrice for symbol in symbols])
    symbols = [symbol for symbol in symbols if symbol.ID.StrikePrice == strike]
    return option_filter_universe.Contracts(symbols)
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Navigate Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security. They have the following properties:

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` . After you get the `OptionChain` , you can sort and filter the Option contracts in the chain.

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.symbol)
    if chain:
        # Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest
expiration
        contracts = [x for x in chain if x.Right == OptionRight.Put]
        contracts = sorted(sorted(contracts, \
            key = lambda x: abs(chain.Underlying.Price - x.Strike)), \
            key = lambda x: x.Expiry, reverse=True)[:5]

        # Select the contract with the delta closest to -0.5
        contract = sorted(contracts, key=lambda x: abs(-0.5 - x.Greeks.Delta))[0]
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```
def OnData(self, slice: Slice) -> None:
    for canonical_symbol, chain in slice.OptionChains.items():
        contracts = chain.Contracts
```

Selection Frequency

By default, Equity Option universes run at every time step to select their contracts. If you add the `OnlyApplyFilterAtMarketOpen` method to your contract filter, the universe selects contracts once a day at the first time step.

Live Trading Considerations

By default, LEAN adds contracts to the `OptionChain` that pass the filter criteria at every time step in your algorithm. If a contract has been in the universe for a duration that matches the `MinimumTimeInUniverse` setting and it no longer passes the filter criteria, LEAN removes it from the chain.

This default behavior can lead to a large number of open data subscriptions, which can be inconvenient in live trading

since some data feed providers impose data subscription limits. To reduce the number of data subscriptions, change the value of the `MinimumTimeInUniverse` universe setting .

```
self.UniverseSettings.MinimumTimeInUniverse = timedelta(minutes=15)
self.UniverseSettings.MinimumTimeInUniverse = timedelta(0)
```

If you set the value to `timedelta(0)` , LEAN removes all of the contract subscriptions at every time step and your data provider stops sending the data. If your filter re-selects some of the same contracts when it runs next, LEAN requests new data subscriptions from your data provider. To avoid unsubscribing and resubscribing to the same contracts at every time step, use a `timedelta` greater than 0.

Universes

Crypto

Introduction

A Crypto universe lets you select a basket of Cryptocurrencies based on `CryptoCoarseFundamental` data.

Crypto Universes

To add a universe of Cryptocurrencies, in the `Initialize` method, pass a `CryptoCoarseFundamentalUniverse` to the `AddUniverse` method.

```
def Initialize(self) -> None:
    self.UniverseSettings.Resolution = Resolution.Daily
    self.SetBrokerageModel(BrokerageName.GDAX, AccountType.Cash)

    # Add universe selection of cryptos based on coarse fundamentals
    filter_function = lambda crypto_coarse: [c.Symbol for c in crypto_coarse]
    self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.GDAX, self.UniverseSettings, filter_function))
```

PY

The following table describes the `CryptoCoarseFundamentalUniverse` constructor arguments:

Argument	Data Type	Description	Default Value
`market`	`str`	The market of the Cryptocurrencies. To view the available Crypto markets, see the CoinAPI datasets .	
`universeSettings`	`UniverseSettings`	The universe settings .	
`universeFilterFunc`	`Callable[[List[CryptoCoarseFundamental]], List[Symbol]]`	A function to select some of the Cryptocurrencies for the universe.	

The filter function receives `CryptoCoarseFundamental` objects, which represent one of the Cryptocurrencies in the market. The `Symbol` objects that the filter function returns represent the universe constituents. `CryptoCoarseFundamental` objects have the following attributes:

To perform thorough filtering on the `CryptoCoarseFundamental` objects, define an isolated filter method.

```py
def Initialize(self) -> None:
    self.UniverseSettings.Resolution = Resolution.Daily
    self.SetBrokerageModel(BrokerageName.GDAX, AccountType.Cash)

    # Add universe selection of cryptos based on coarse fundamentals
    self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.GDAX, self.UniverseSettings,
self.universe_filter))

def universe_filter(self, crypto_coarse: List[CryptoCoarseFundamental]) -> List[Symbol]:
    # Define the universe selection function
    return [cf.Symbol for cf in crypto_coarse if cf.Volume >= 100 and cf.VolumeInUsd > 10000]
```

Selection Frequency

Crypto universes run on a daily basis.

Live Trading Considerations

In live mode, the pipeline has a 16-hour delay. Your algorithm receives the `CryptoCoarseFundamental` objects at around 16:00-16:30 Coordinated Universal Time (UTC) each day, depending on the data processing task.

Universes

Futures

Introduction

A Futures universe lets you select a basket of contracts for a single Future. LEAN models Future subscriptions as a universe of Future contracts. A Future universe is similar to an Option universe , except Future contracts don't have a strike price, so the universe filter primarily focuses on the contract expiration date.

Create Universes

To add a universe of Future contracts, in the `Initialize` method, call the `AddFuture` method. This method returns an `Future` object, which contains the continuous contract `Symbol` . The `continuous contract Symbol` is the key to access the contracts in the FutureChain that LEAN passes to the `OnData` method. When you create the Future subscription, save a reference to the `continuous contract Symbol` so you can use it later in your algorithm.

```
self.future = self.AddFuture(Futures.Currencies.BTC)
self.symbol = self.future.Symbol
```

The following table describes the `AddFuture` method arguments:

Argument: `ticker` The Future ticker. To view the supported assets in the US Futures dataset, see Supported Assets . Data Type: `str` | Default Value: None
Argument: `resolution` The resolution of the market data. To view the supported resolutions, see Resolutions . If you don't provide a value, it uses `Resolution.Minute` by default. Data Type: `Resolution/NoneType` | Default Value: `None`
Argument: `market` The Futures market. To view the supported markets in the US Futures dataset, see Supported Markets . If you don't provide a value, it uses the default Future market of your brokerage model . Data Type: `str` | Default Value: `None`

Argument: `fillForward`

If true, the current slice contains the last available data even if there is no data at the current time.

Data Type: `bool` | Default Value: `True`

Argument: `leverage`

The leverage for this Future.

Data Type: `float` | Default Value: `Security.NullLeverage`

Argument: `extendedMarketHours`

If true, use data from the pre and post market sessions

Data Type: `bool` | Default Value: `False`

Argument: `dataMappingMode`

The contract mapping mode to use for the continuous future contract

Data Type: `DataMappingMode/NoneType` | Default Value: `None`

Argument: `dataNormalizationMode`

The price scaling mode to use for the continuous future contract

Data Type: `DataNormalizationMode/NoneType` | Default Value: `None`

Argument: `contractDepthOffset`

The continuous future contract desired offset from the current front month. For example, 0 is the front month, 1 is the back month contract.

Data Type: `int` | Default Value: `0`

Continous Contracts

By default, LEAN only subscribes to the continuous Future contract. A continuous Future contract represents a series of separate contracts stitched together to form a continuous price. If you need a lot of historical data to warm up an indicator, apply the indicator to the continuous contract price series. The `Future` object has a `Symbol` property and a `Mapped` property. The price of the `Symbol` property is the adjusted price of the continuous contract. The price of the

`Mapped` property is the raw price of the currently selected contract in the continuous contract series.

```
# Get the adjusted price of the continuous contract
adjusted_price = self.Securities[self.future.Symbol].Price

# Get the raw price of the currently selected contract in the continuous contract series
raw_price = self.Securities[self.future.Mapped].Price
```

To configure how LEAN identifies the current Future contract in the continuous series and how it forms the adjusted price between each contract, provide `dataMappingMode` , `dataNormalizationMode` , and `contractDepthOffset` arguments to the `AddFuture` method. The `Future` object that the `AddFuture` method returns contains a `Mapped` property that references the current contract in the continuous contract series. As the contracts roll over, the `Mapped` property references the next contract in the series and you receive a `SymbolChangedEvent` object in the `OnData` method. The `SymbolChangedEvent` references the old contract `Symbol` and the new contract `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    for changed_event in slice.SymbolChangedEvents.Values:
        self.Log(f"Contract rollover from {changed_event.OldSymbol} to {changed_event.NewSymbol}")
```

Data Normalization Modes

The `dataNormalizationMode` argument defines how the price series of two contracts are stitched together when the contract rollovers occur. The following `DataNormalizatoinMode` enumeration members are available for continuous contracts:

We use the entire Futures history to adjust historical prices. This process ensures you get the same adjusted prices, regardless of the backtest end date.

Data Mapping Modes

The `dataMappingMode` argument defines when contract rollovers occur. The `DataMappingMode` enumeration has the following members:

Contract Depth Offsets

The `contractDepthOffset` argument defines which contract to use. 0 is the front month contract, 1 is the following back month contract, and 3 is the second back month contract.

Filter Contracts

By default, LEAN doesn't add any contracts to the FuturesChain it passes to the `OnData` method. To add a universe of Future contracts, in the `Initialize` method, call the `SetFilter` method of the `Future` object. The following table describes the available filter techniques:

Method	Description
`SetFilter(minExpiryDays: int, maxExpiryDays: int)`	Selects the contracts that expire within the range you set.
`SetFilter(universeFunc: Callable[[FutureFilterUniverse], FutureFilterUniverse])`	Selects the contracts that a function selects.

```py
# Select the contracts which expire within 182 days
self.future.SetFilter(0, 182)

# Select the front month contract
self.future.SetFilter(lambda future_filter_universe: future_filter_universe.FrontMonth())
```

The following table describes the filter methods of the `FutureFilterUniverse` class:

Method	Description
`StandardsOnly()`	Selects standard contracts
`IncludeWeeklys()`	Selects non-standard weekly contracts
`WeeklysOnly()`	Selects weekly contracts
`FrontMonth()`	Selects the front month contract
`BackMonths()`	Selects the non-front month contracts
`BackMonth()`	Selects the back month contracts
`Expiration(minExpiry: timedelta, maxExpiry: timedelta)`	Selects contracts that expire within a range of dates relative to the current day
`Expiration(minExpiryDays: int, maxExpiryDays: int)`	Selects contracts that expire within a range of dates relative to the current day
`Contracts(contracts: List[Symbol])`	Selects a list of contracts
`Contracts(contractSelector: Callable[[List[Symbol]], List[Symbol]])`	Selects contracts that a selector function selects
`OnlyApplyFilterAtMarketOpen()`	Instructs the engine to only filter contracts on the first time step of each market day

The preceding methods return an `FutureFilterUniverse` , so you can chain the methods together.

```py
# Select the front month standard contracts
self.future.SetFilter(lambda future_filter_universe: future_filter_universe.StandardsOnly().FrontMonth())
```

You can also define an isolated filter method.

```
# In Initialize
self.future.SetFilter(self.contract_selector)

def contract_selector(self,
    future_filter_universe: Callable[[FutureFilterUniverse], FutureFilterUniverse]) ->
FutureFilterUniverse:
    return future_filter_universe.StandardsOnly().FrontMonth()
```

Some of the preceding filter methods only set an internal enumeration in the `FutureFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `FutureFilterUniverse` .

By default, LEAN adds contracts to the `FutureChain` that pass the filter criteria at every time step in your algorithm. If a contract has been in the universe for a duration that matches the `MinimumTimeInUniverse` setting and it no longer passes the filter criteria, LEAN removes it from the chain

Navigate Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. They have the following properties:

To get the `FuturesChain` , index the `FuturesChains` property of the `Slice` with the continuous contract `Symbol` .

```
def OnData(self, slice: Slice) -> None:
    chain = slice.FuturesChains.get(self.symbol)
    if chain:
        # Example: Select the contract with the greatest open interest
        contract = sorted(chain, key=lambda contract: contract.OpenInterest, reverse=True)[0]
```

You can also loop through the `FuturesChains` property to get each `FuturesChain` .

```
def OnData(self, slice: Slice) -> None:
    for continuous_contract_symbol, chain in slice.FuturesChains.items():
        pass
```

Selection Frequency

By default, Futures universes run at every time step to select their contracts. If you add the `OnlyApplyFilterAtMarketOpen` method to your contract filter, the universe selects contracts once a day at the first time step.

Universes

Future Options

Introduction

A Future Option universe lets you select a basket of Option contracts on the contracts in a Futures universe .

Create Universes

To add a universe of Future Option contracts, in the `Initialize` method, define a Future universe and then pass the canonical `Symbol` to the `AddFutureOption` method.

```
future = self.AddFuture(Futures.Metals.Gold)
future.SetFilter(0, 90)
self.AddFutureOption(future.Symbol)
```

PY

The following table describes the `AddFutureOption` method arguments:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The continuous Future contract Symbol. To view the supported assets in the US Future Options dataset, see Supported Assets .	
`optionFilter`	`Callable[[OptionFilterUniverse], OptionFilterUniverse]`	A function that selects Future Option contracts	`None`

To override the default pricing model of the Option, set a pricing model in a security initializer.

```
# In Initialize
seeder = SecuritySeeder.Null
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel, seeder, self))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder, algorithm:
QCAlgorithm) -> None:
        super().__init__(brokerage_model, security_seeder)
        self.algorithm = algorithm

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, set the price model
        if security.Type == SecurityType.FutureOption: # Option type
            security.PriceModel = OptionPriceModels.CrankNicolsonFD()
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Filter Contracts

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 31 days

To adjust the universe of contracts, set a filter. The filter usually runs at every time step in your algorithm. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

To set a contract filter, in the `Initialize` method, pass a filter function to the `AddFutureOption` method. The following table describes the available filter techniques:

```
self.AddFutureOption(future.Symbol, lambda option_filter_universe: option_filter_universe.Strikes(-1, 1))
```

The following table describes the filter methods of the `OptionFilterUniverse` class:

Method	Description
`Strikes(minStrike: int, maxStrike: int)`	Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price
`CallsOnly()`	Selects call contracts
`PutsOnly()`	Selects put contracts
`StandardsOnly()`	Selects standard contracts
`IncludeWeeklys()`	Selects non-standard weeklys contracts
`WeeklysOnly()`	Selects weekly contracts
`FrontMonth()`	Selects the front month contract
`BackMonths()`	Selects the non-front month contracts
`BackMonth()`	Selects the back month contracts
`Expiration(minExpiry: timedelta, maxExpiry: timedelta)`	Selects contracts that expire within a range of dates relative to the current day
`Expiration(minExpiryDays: int, maxExpiryDays: int)`	Selects contracts that expire within a range of dates relative to the current day
`Contracts(contracts: List[Symbol])`	Selects a list of contracts
`Contracts(contractSelector: Callable[[List[Symbol]], List[Symbol]])`	Selects contracts that a selector function selects
`OnlyApplyFilterAtMarketOpen()`	Instructs the engine to only filter contracts on the first time step of each market day

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
self.AddFutureOption(future.Symbol, lambda option_filter_universe: option_filter_universe.Strikes(-1,
1).CallsOnly())
```

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```
# In Initialize
self.AddFutureOption(future.Symbol, self.contract_selector)

def contract_selector(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    symbols = option_filter_universe.PutsOnly()
    strike = min([symbol.ID.StrikePrice for symbol in symbols])
    symbols = [symbol for symbol in symbols if symbol.ID.StrikePrice == strike]
    return option_filter_universe.Contracts(symbols)
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Navigate Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security. They have the following properties:

To get the `OptionChain` , loop through the `OptionChains` property. After you get the `OptionChain` , you can sort and filter the Option contracts in the chain.

```
PY
def OnData(self, slice: Slice) -> None:
    for _, option_chain in slice.OptionChains.items():
        # Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest
expiration
        contracts = [x for x in option_chain if x.Right == OptionRight.Put]
        contracts = sorted(sorted(contracts, \
            key = lambda x: abs(option_chain.Underlying.Price - x.Strike)), \
            key = lambda x: x.Expiry, reverse=True)[:5]

        # Select the contract with the delta closest to -0.5
        contract = sorted(contracts, key=lambda x: abs(-0.5 - x.Greeks.Delta))[0]
```

You can also iterate through the `FuturesChains` first.

```
PY
def OnData(self, slice: Slice) -> None:
    for continuous_future_symbol, futures_chain in slice.FuturesChains.items():
        # Select a Future Contract and create its canonical FOP Symbol
        futures_contract = [contract for contract in futures_chain][0]
        canonical_fop_symbol = Symbol.CreateCanonicalOption(futures_contract.Symbol)
        fop_chain = slice.OptionChains.get(canonical_fop_symbol)
        if fop_chain:
            for contract in fop_chain:
                pass
```

Selection Frequency

By default, Future Option universes run at every time step to select their contracts. If you add the `OnlyApplyFilterAtMarketOpen` method to your contract filter, the universe selects contracts once a day at the first time step.

Live Trading Considerations

By default, LEAN adds contracts to the `OptionChain` that pass the filter criteria at every time step in your algorithm. If a contract has been in the universe for a duration that matches the `MinimumTimeInUniverse` setting and it no longer passes the filter criteria, LEAN removes it from the chain.

This default behavior can lead to a large number of open data subscriptions, which can be inconvenient in live trading since some data feed providers impose data subscription limits. To reduce the number of data subscriptions, change the value of the `MinimumTimeInUniverse` universe setting .

```
self.UniverseSettings.MinimumTimeInUniverse = timedelta(minutes=15)
self.UniverseSettings.MinimumTimeInUniverse = timedelta(0)
```

If you set the value to `timedelta(0)` , LEAN removes all of the contract subscriptions at every time step and your data provider stops sending the data. If your filter re-selects some of the same contracts when it runs next, LEAN requests new data subscriptions from your data provider. To avoid unsubscribing and resubscribing to the same contracts at every time step, use a `timedelta` greater than 0.

Universes

Index Options

Introduction

An Index Option universe lets you select a basket of Option contracts on an Index.

Create Universes

To add a universe of Index Option contracts, in the `Initialize` method, call the `AddIndexOption` method. This method returns an `Option` object, which contains the canonical `Symbol` . You can't trade with the canonical Option `Symbol` , but save a reference to it so you can easily access the Option contracts in the OptionChain that LEAN passes to the `OnData` method. The method to create the universe depends on if the Index Options you want require a target ticker.

Create Standard Universes

To create a universe of Index Options based on an index like VIX, SPX, or NDX, pass the index ticker to the `AddIndexOption` method.

```
option = self.AddIndexOption("VIX")
self.symbol = option.Symbol
```

The following table describes the `AddIndexOption` method arguments for standard universes:

Argument	Data Type	Description	Default Value
`ticker`	`str`	The underlying Index ticker. To view the supported indices, see Supported Assets .	
`resolution`	`Resolution/NoneType`	The resolution of the market data. To view the supported resolutions, see Resolutions .	`None`
`market`	`str`	The Index Option market.	`Market.USA`
`fillForward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.	`True`

If you add an Option universe for an underlying Index that you don't have a subscription for, LEAN automatically subscribes to the underlying Index and sets its fill forward property to match that of the Index Option universe

Create Non-Standard Universes

To create a universe of non-standard Index Options like weekly VIX contracts, pass the index Symbol and target Option

ticker to the `AddIndexOption` method.

```
index_symbol = self.AddIndex("VIX").Symbol
option = self.AddIndexOption(index_symbol, "VIXW")
self.symbol = option.Symbol
```

The following table describes the `AddIndexOption` method arguments for non-standard universes:

Argument	Data Type	Description	Default Value
`underlying`	`Symbol`	The underlying Index `Symbol` . To view the supported indices, see Supported Assets .	
`targetOption`	`str`	The target Option ticker. To view the supported target Options, see Supported Assets .	
`resolution`	`Resolution/NoneType`	The resolution of the market data. To view the supported resolutions, see Resolutions . The Index resolution must be less than or equal to the Index Option resolution. For example, if you set the Index resolution to minute, then you must set the Index Option resolution to minute, hour, or daily.	`None`
`market`	`str`	The Index Option market.	`Market.USA`
`fillForward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.	`True`

If you add an Option universe for an underlying Index that you don't have a subscription for, LEAN automatically subscribes to the underlying Index.

Configure Reality Models

To override the default pricing model of the Option, set a pricing model .

```
option.PriceModel = OptionPriceModels.CrankNicolsonFD()
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Filter Contracts

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 31 days

To adjust the universe of contracts, set a filter. The filter usually runs at every time step in your algorithm. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

To set a contract filter, in the `Initialize` method, call the `SetFilter` method of the `Option` object. The following table describes the available filter techniques:

Method	Description
`SetFilter(minStrike: int, maxStrike: int)`	Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302*andthereare*strikesatevery5. If you set `minStrike` to -1 and `maxStrike` to 1, LEAN selects the contracts that have a strike of 300*or*305.
`SetFilter(minExpiry: timedelta, maxExpiry: timedelta)`	Selects the contracts that expire within the range you set.
`SetFilter(minStrike: int, maxStrike: int, minExpiry: timedelta, maxExpiry: timedelta)`	Selects the contracts that expire and have a strike within the range you set.
`SetFilter(universeFunc: Callable[[OptionFilterUniverse], OptionFilterUniverse])`	Selects the contracts that a function selects.

PY

```
# Select contracts that have a strike price within 1 strike level above and below the underlying price
option.SetFilter(minStrike=-1, maxStrike=1)

# Select contracts that expire within 30 days
option.SetFilter(minExpiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select contracts that have a strike price within 1 strike level and expire within 30 days
option.SetFilter(minStrike=-1, maxStrike=1, minExpiry=timedelta(days=0), maxExpiry=timedelta(days=30))

# Select call contracts
option.SetFilter(lambda option_filter_universe: option_filter_universe.CallsOnly())
```

The following table describes the filter methods of the `OptionFilterUniverse` class:

Method	Description
`Strikes(minStrike: int, maxStrike: int)`	Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price
`CallsOnly()`	Selects call contracts
`PutsOnly()`	Selects put contracts
`StandardsOnly()`	Selects standard contracts
`IncludeWeeklys()`	Selects non-standard weeklys contracts
`WeeklysOnly()`	Selects weekly contracts
`FrontMonth()`	Selects the front month contract
`BackMonths()`	Selects the non-front month contracts
`BackMonth()`	Selects the back month contracts
`Expiration(minExpiry: timedelta, maxExpiry: timedelta)`	Selects contracts that expire within a range of dates relative to the current day
`Expiration(minExpiryDays: int, maxExpiryDays: int)`	Selects contracts that expire within a range of dates relative to the current day
`Contracts(contracts: List[Symbol])`	Selects a list of contracts
`Contracts(contractSelector: Callable[[List[Symbol]], List[Symbol]])`	Selects contracts that a selector function selects
`OnlyApplyFilterAtMarketOpen()`	Instructs the engine to only filter contracts on the first time step of each market day

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```py
# Example 1: Select the front month call contracts
option.SetFilter(lambda option_filter_universe: option_filter_universe.CallsOnly().FrontMonth())

# Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.SetFilter(lambda option_filter_universe: option_filter_universe.IncludeWeeklys().Strikes(-20,
20).Expiration(0, 90))
```

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```py
# In Initialize
option.SetFilter(self.contract_selector)

def contract_selector(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    symbols = option_filter_universe.PutsOnly()
    strike = min([symbol.ID.StrikePrice for symbol in symbols])
    symbols = [symbol for symbol in symbols if symbol.ID.StrikePrice == strike]
    return option_filter_universe.Contracts(symbols)
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Navigate Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security. They have the following properties:

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` . After you get the `OptionChain` , you can sort and filter the Option contracts in the chain.

```py
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.symbol)
    if chain:
        # Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest
expiration
        contracts = [x for x in chain if x.Right == OptionRight.Put]
        contracts = sorted(sorted(contracts, \
            key = lambda x: abs(chain.Underlying.Price - x.Strike)), \
            key = lambda x: x.Expiry, reverse=True)[:5]

        # Select the contract with the delta closest to -0.5
        contract = sorted(contracts, key=lambda x: abs(-0.5 - x.Greeks.Delta))[0]
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```py
def OnData(self, slice: Slice) -> None:
    for canonical_symbol, chain in slice.OptionChains.items():
        contracts = chain.Contracts
```

Selection Frequency

By default, Index Option universes run at every time step to select their contracts. If you add the `OnlyApplyFilterAtMarketOpen` method to your contract filter, the universe selects contracts once a day at the first time step.

Live Trading Considerations

By default, LEAN adds contracts to the `OptionChain` that pass the filter criteria at every time step in your algorithm. If a contract has been in the universe for a duration that matches the `MinimumTimeInUniverse` setting and it no longer passes the filter criteria, LEAN removes it from the chain.

This default behavior can lead to a large number of open data subscriptions, which can be inconvenient in live trading

since some data feed providers impose data subscription limits. To reduce the number of data subscriptions, change the value of the `MinimumTimeInUniverse` universe setting .

```
self.UniverseSettings.MinimumTimeInUniverse = timedelta(minutes=15)
self.UniverseSettings.MinimumTimeInUniverse = timedelta(0)
```

PY

If you set the value to `timedelta(0)` , LEAN removes all of the contract subscriptions at every time step and your data provider stops sending the data. If your filter re-selects some of the same contracts when it runs next, LEAN requests new data subscriptions from your data provider. To avoid unsubscribing and resubscribing to the same contracts at every time step, use a `timedelta` greater than 0.

Universes

Custom Universes

Introduction

A custom universe lets you select a basket of assets from a custom dataset.

Data Sources

You can gather your custom data from any of the following sources:

The data source should serve data in chronological order and each data point should have a unique timestamp. Each request has a 1 second overhead, so bundle samples together for fast execution.

Define Custom Universe Types

Custom universes should extend the `PythonData` class. Extensions of the `PythonData` class must implement a `GetSource` and `Reader` method.

The `GetSource` method in your custom data class instructs LEAN where to find the data. This method must return a `SubscriptionDataSource` object, which contains the data location and format (`SubscriptionTransportMedium`). You can even change source locations for backtesting and live modes. We support many different data sources.

The `Reader` method of your custom data class takes one line of data from the source location and parses it into one of your custom objects. You can add as many properties to your custom data objects as you need, but must set `Symbol` and `EndTime` properties. When there is no useable data in a line, the method should return `None` . LEAN repeatedly calls the `Reader` method until the date/time advances or it reaches the end of the file.

PY

```
# Example custom universe data; it is virtually identical to other custom data types.
class MyCustomUniverseDataClass(PythonData):

    def GetSource(self, config: SubscriptionDataConfig, date: datetime, isLiveMode: bool) ->
SubscriptionDataSource:
        return SubscriptionDataSource(@"your-remote-universe-data",
SubscriptionTransportMedium.RemoteFile)

    def Reader(self, config: SubscriptionDataConfig, line: str, date: datetime, isLiveMode: bool) ->
BaseData:
        items = line.split(",")

        # Generate required data, then return an instance of your class.
        data = MyCustomUniverseDataClass()
        data.EndTime = datetime.strptime(items[0], "%Y-%m-%d")
        # define Time as exactly 1 day earlier Time
        data.Time = data.EndTime - timedelta(1)
        data.Symbol = Symbol.Create(items[1], SecurityType.Crypto, Market.Bitfinex)
        data["CustomAttribute1"] = int(items[2])
        data["CustomAttribute2"] = float(items[3])
        return data
```

Your `Reader` method should return objects in chronological order. If an object has a timestamp that is the same or earlier than the timestamp of the previous object, LEAN ignores it.

If you need to create multiple objects in your `Reader` method from a single `line` , follow these steps:

1. In the `GetSource` method, pass `FileFormat.UnfoldingCollection` as the third argument to the `SubscriptionDataSource` constructor.
2. In the `Reader` method, order the objects by their timestamp and then return a `BaseDataCollection(endTime, config.Symbol, objects)` where `objects` is a list of your custom data objects.

```
class MyCustomUniverseDataClass(PythonData):

    def GetSource(self, config, date, isLive):
        return SubscriptionDataSource("your-data-source-url", SubscriptionTransportMedium.RemoteFile,
FileFormat.UnfoldingCollection)

    def Reader(self, config, line, date, isLive):
        json_response = json.loads(line)

        endTime = datetime.strptime(json_response[-1]["date"], '%Y-%m-%d') + timedelta(1)

        data = list()

        for json_datum in json_response:
            datum = MyCustomUniverseDataClass()
            datum.Symbol = Symbol.Create(json_datum["Ticker"], SecurityType.Equity, Market.USA)
            datum.Time = datetime.strptime(json_datum["date"], '%Y-%m-%d')
            datum.EndTime = datum.Time + timedelta(1)
            datum['CustomAttribute1'] = int(json_datum['Attr1'])
            datum.Value = float(json_datum['Attr1'])
            data.append(datum)

        return BaseDataCollection(endTime, config.Symbol, data)
```

Initialize Custom Universes

To add a custom universe to your algorithm, in the `Initialize` method, pass your universe type and a selector function to the `AddUniverse` method. The selector function receives a list of your custom objects and must return a list of `Symbol` objects. In the selector function definition, you can use any of the properties of your custom data type. The `Symbol` objects that you return from the selector function set the constituents of the universe.

```
# In Initialize
self.AddUniverse(MyCustomUniverseDataClass, "myCustomUniverse", Resolution.Daily, self.selector_function)

# Define the selector function
def selector_function(self, data: List[MyCustomUniverseDataClass]) -> List[Symbol]:
    sorted_data = sorted([ x for x in data if x["CustomAttribute1"] > 0 ],
                         key=lambda x: x["CustomAttribute2"],
                         reverse=True)
    return [x.Symbol for x in sorted_data[:5]]
```

Selection Frequency

Custom universes run on a schedule based on the `EndTime` of your custom data objects.

Examples

Demonstration Algorithms
DropboxUniverseSelectionAlgorithm.py Python

Universes

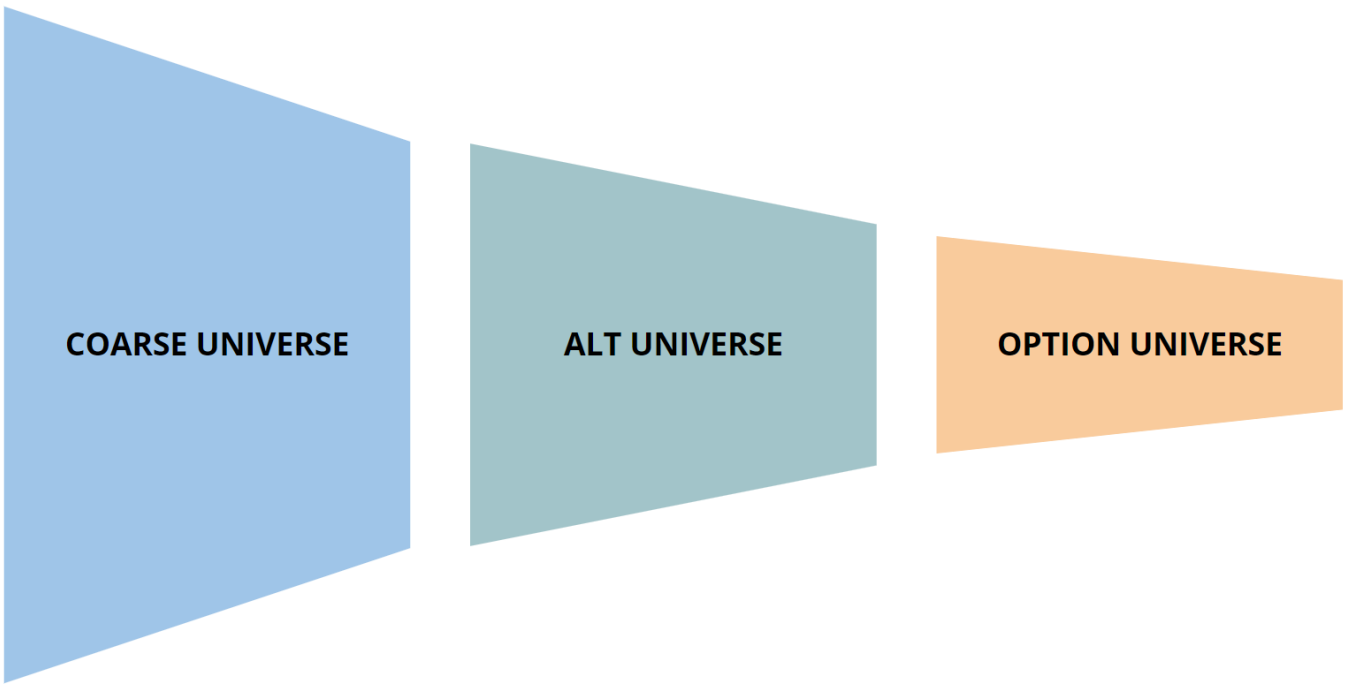
Chained Universes

Introduction

You can combine ("chain") universes together to fetch fundamental and alternative data on a specific subset of assets. Universes filter input data and return `Symbol` objects. The only requirement is that `Symbol` objects the filter returns are a subset of the input data. The source of the `Symbol` objects is unrestricted, so you can feed the output of one universe into another.

Filter Pattern

Universes filter a large set of Symbol objects by a coarse filter to quickly reduce the data processing requirement. This is often a first step before applying a second filter or requesting alternative data. For example, a strategy might only be interested in easily tradable liquid assets so quickly eliminates all stocks with less than $1M USD / day in trading volume.



The order of your filters can improve the speed of your research. By applying filters that narrow the universe the most, or are the lightest weight first, you can significantly reduce the amount of data your algorithm processes. Unless necessary, you can also not return any selections from earlier filters to further improve research speed, keeping only the universe data for later filters.

Universe Data Weights

To speed up your algorithm, request the lightest weight data first before chaining heavier filters or adding alternative data. The following table shows the size each dataset:

Name	Data Size / Weight
US Equities (Coarse)	Light (1 GB)
US Equities (Fine/Fundamental)	Heavy (5 TB)
US Equity Options	Huge (200 TB)
US Index Options	Medium (500 GB)
US Futures	Medium (500 GB)
US Futures Options	Medium (500 GB)
Crypto	Light (1 GB)
Alternative / General	Light (100 MB - 2 GB)
Alternative / Tiingo News	Medium (200 GB)

Universe Schedules

Universes typically run overnight and are available before market open. Universes are not currently "ordered", so universe chaining works best with slower universes. For example, use a slow-changing ETF Constituents Universe to set the Symbol list for alternative data.

Chaining Coarse and Alternative Data

The following example chains the QuiverQuantTwitterFollowersUniverse alternative universe to the coarse universe . It first selects the 100 most liquid US Equities and then filters them down based on their Twitter followers number and weekly change. The output of the alternative universe selection method is the output of the chained universe.

```
from AlgorithmImports import *

class ChainedUniverseAlgorithm(QCAlgorithm):

    coarse = []
    universe_coarse = None
    universe_twitter = None

    def Initialize(self):
        self.SetCash(100000)
        self.SetStartDate(2023, 1, 2)
        self.universe_coarse = self.AddUniverse(self.CoarseFilterFunction)
        self.universe_twitter = self.AddUniverse(QuiverQuantTwitterFollowersUniverse,
"QuiverQuantTwitterFollowersUniverse", Resolution.Daily, self.FollowerSelection)

    def CoarseFilterFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        sorted_by_dollar_volume = sorted(coarse, key=lambda x: x.DollarVolume, reverse=True)
        self.coarse = [c.Symbol for c in sorted_by_dollar_volume[:100]]
        return Universe.Unchanged

    def FollowerSelection(self, alt_coarse: List[QuiverQuantTwitterFollowersUniverse]) -> List[Symbol]:
        self.followers = [d.Symbol for d in alt_coarse if d.Followers > 200000 and d.WeekPercentChange >
0]
        return list(set(self.coarse) & set(self.followers))

    def OnSecuritiesChanged(self, changes):
        for added in changes.AddedSecurities:
            self.AddData(QuiverQuantTwitterFollowers, added.Symbol)

    def OnData(self, data):
        # Prices in the slice from the universe selection
        # Alternative data in slice from OnSecuritiesChanged Addition
        # for ticker,bar in data.Bars.items():
        #     pass
        for dataset_symbol, data_point in data.Get(QuiverQuantTwitterFollowers).items():
            self.Debug(f"{dataset_symbol} followers at {data.Time}: {data_point.Followers}")
```

Chaining ETF Universe and Alt Data

The following example chains a QuiverQuantTwitterFollowersUniverse alternative universe to the SPY ETF universe . It first selects all constituents of SPY and then filters them down with based on their Twitter followers number and weekly change. The output of the alternative universe selection method is the output of the chained universe.

```
PY
```

```python
from AlgorithmImports import *

class ChainedUniverseAlgorithm(QCAlgorithm):

    etf = []
    universe_etf = None
    universe_twitter = None

    def Initialize(self):
        self.SetCash(100000)
        self.SetStartDate(2023, 1, 2)

        self.universe_etf = self.AddUniverse(self.Universe.ETF("SPY", Market.USA, self.UniverseSettings,
self.ETFConstituentsFilter))
        # or symbol = Symbol.Create("SPY", SecurityType.Equity, Market.USA)
        # self.universe_etf = self.AddUniverseSelection(ETFConstituentsUniverseSelectionModel(
        #   symbol, self.UniverseSettings, self.ETFConstituentsFilter))
        self.universe_twitter = self.AddUniverse(QuiverQuantTwitterFollowersUniverse,
            "QuiverQuantTwitterFollowersUniverse", Resolution.Daily, self.FollowerSelection)

    def ETFConstituentsFilter(self, constituents: List[ETFConstituentData]) -> List[Symbol]:
        self.etf = [c.Symbol for c in constituents]
        return Universe.Unchanged

    def FollowerSelection(self, alt_coarse: List[QuiverQuantTwitterFollowersUniverse]) -> List[Symbol]:
        self.followers = [d.Symbol for d in alt_coarse if d.Followers > 200000 and d.WeekPercentChange >
0]
        return list(set(self.etf) & set(self.followers))

    def OnSecuritiesChanged(self, changes):
        for added in changes.AddedSecurities:
            self.AddData(QuiverQuantTwitterFollowers, added.Symbol)

    def OnData(self, data):
        # Prices in the slice from the universe selection
        # Alternative data in slice from OnSecuritiesChanged Addition
        # for ticker,bar in data.Bars.items():
        #     pass
        for dataset_symbol, data_point in data.Get(QuiverQuantTwitterFollowers).items():
            self.Debug(f"{dataset_symbol} followers at {data.Time}: {data_point.Followers}")
```

Chaining to US Equity Options

The following example chains an `OptionFilterUniverse` to the QQQ ETF universe . It first selects the 30 largest-weighted constituents of QQQ and then selects their call Option contracts that expire within 60 days.

```
from AlgorithmImports import *

class ChainedUniverseAlgorithm(QCAlgorithm):

    universe_etf = None
    option_contracts = []

    def Initialize(self):
        self.SetCash(100000)
        self.SetStartDate(2023, 2, 2)

        self.UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw
        self.universe_etf = self.AddUniverse(self.Universe.ETF("QQQ", Market.USA, self.UniverseSettings,
self.ETFConstituentsFilter))

    def ETFConstituentsFilter(self, constituents: List[ETFConstituentData]) -> List[Symbol]:
        sorted_by_weight = sorted(constituents, key=lambda x: x.Weight, reverse=True)
        return [c.Symbol for c in sorted_by_weight[:10]]

    def OnSecuritiesChanged(self, changes: SecurityChanges) -> None:
        for added in changes.AddedSecurities:
            if added.Type != SecurityType.Equity: continue

            contracts = self.OptionChainProvider.GetOptionContractList(added.Symbol, self.Time)
            filtered_contracts = [self.AddOptionContract(contract).Symbol for contract in contracts \
                                  if contract.ID.OptionRight == OptionRight.Call \
                                  and contract.ID.StrikePrice >= 100 \
                                  and contract.ID.Date <= self.Time + timedelta(10) \
                                  and contract.ID.OptionStyle == OptionStyle.American]
            self.option_contracts = self.option_contracts + filtered_contracts

        for removed in changes.RemovedSecurities:
            if removed.Symbol in self.option_contracts:
                self.option_contracts.remove(removed.Symbol)

    def OnData(self, data: Slice) -> None:
        for chain in data.OptionChains:
            symbol = chain.Key
            for contract in chain.Value:
                self.Debug(f"Found {contract.Symbol} option contract for {symbol}")
```

Chaining ETF and Fundamental Universe

The following example chains an ETF constituents universe with a fundamental universe to select ETF constituents with a low PE ratio.

PY

```
from AlgorithmImports import *

class ChainedUniverseAlgorithm(QCAlgorithm):

    universe_etf = None
    universe_fine = None

    def Initialize(self):
        self.SetCash(100000)
        self.SetStartDate(2023, 2, 2)

        self.universe_etf = self.Universe.ETF("QQQ", Market.USA, self.UniverseSettings,
self.ETFConstituentsFilter)
        self.universe_fine = self.AddUniverse(self.universe_etf, self.FineSelection)

    def ETFConstituentsFilter(self, constituents: List[ETFConstituentData]) -> List[Symbol]:
        return [c.Symbol for c in constituents]

    def FineSelection(self, fine: List[FineFundamental]) -> List[Symbol]:
        sorted_by_pe_ratio = sorted(fine, key=lambda f: f.ValuationRatios.PERatio)
        return [f.Symbol for f in sorted_by_pe_ratio[:20]]

    def OnData(self, data):
        for symbol in data.Keys:
            self.Debug(f"{symbol} PE Ratio:
{self.Securities[symbol].Fundamentals.ValuationRatios.PERatio}")
```

Universes

Alternative Data Universes

Introduction

An alternative data universe lets you select a basket of assets based on an alternative dataset that's linked to securities. If you use an alternative data universe, you limit your universe to only the securities in the dataset, which avoids unnecessary subscriptions.

Supported Datasets

The following alternative datasets support universe selection:

- US Congress Trading
- Wikipedia Page Views
- WallStreetBets
- Corporate Buybacks
- Brain Sentiment Indicator
- Brain ML Stock Ranking
- Brain Language Metrics on Company Filings
- Twitter Followers
- CNBC Trading
- US Government Contracts
- Corporate Lobbying
- Insider Trading
- Crypto Market Cap

Datasets

Datasets

Overview

Introduction

It's common to use price and fundamental data points to inform trading decisions. Alternative datasets are datasets that aren't classified as market or fundamental data. Alternative data research began gaining popularity in 2007 after the financial crisis and its usage has continued to grow over the years. As usage has grown, so has the number of unique alternative datasets that are available for investors. The benefit of alternative datasets is that it’s easier to find alpha in these datasets because they receive less attention from investment researchers and these datasets contain information not found in market and fundamental datasets. Most traders research with market and fundamental datasets, so it's difficult to find alpha in them.

Methodology

The journey of raw data from its source to its integration with a trading platform can be complex. Alternative data is generally created through individuals, business processes, and sensors. Individuals create content on social media platforms, write reviews on e-commerce sites, and visit corporate Wikipedia pages. Businesses process transactions, file SEC reports, and issue company announcements. Sensors collect location data, gather satellite images, and monitor customer behavior.

Data providers can capture these forms of data for traders to inform trading decisions in ways that supplement traditional market and fundamental datasets. With over a million terabytes of data on the internet, there is virtually a limitless amount of information that can be informative for investors when analyzing a security’s performance in the marketplace.

Examples

A common example of alternative data in a trading system is using sentiment analysis on news sources to predict the future price movements of Equities. A second example is using announcements regarding corporate share buyback programs to trading Equities. A third example is using global supply and demand information for US Crude Products to inform Futures trades. To view all of the datasets we have available, see the left navigation menu.

Challenges

A challenge of working with datasets is that it can be difficult to find a reliable, high-quality, and inexpensive data feed to use in live algorithms. If a data feed has survivorship bias, insufficient history, or hasn’t been cleaned and processed properly, the data feed can cause poor trading performance. We thoroughly vet the datasets we add to the Dataset Market to ensure they are free of survivorship bias and have a reliable live feed. All of the available datasets have

already been cleaned and processed, so you can just focus on the strategy research and development.

Future Outlook

The Dataset Market is still in the early phases of development. Over time, we will add more markets and alternative datasets. Alternative datasets are an ever-expanding data source, so it's expected to continue to grow into the future. In today's digital world, more data is created each year than in the previous year. To take advantage of the trend, we have implemented a new onboarding process to integrate many new alternative data sources into the QuantConnect platform. With the Dataset Market, you can import a new alternative dataset into your trading algorithm with just a single line of code. The Dataset Market gives everyone the ability to access high-quality alternative datasets that were previously only accessible to major hedge funds.

Live Trading Considerations

We receive most daily alternative data at 7 AM Eastern Time (ET) and start processing it. In live trading, your algorithm receives this data within 30 minutes of 7 AM ET. In backtesting, this data has a timestamp of midnight, so your algorithm receives it about seven hours earlier than it does in live mode.

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them milliseconds after the top of each minute.

Note that there will be delay for data available to be backtested. Live feed data is available for backtesting after 24-48 hours normally. Consider using Paper live trading if close monitoring is needed.

Datasets

QuantConnect

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

QuantConnect

Binance Crypto Future Margin Rate Data

Introduction

The Binance Crypto Future Margin Rate Data by QuantConnect is for crypto-currency futures margin interest data points. The data covers 236 Cryptocurrency pairs, starts in August 2020, and is delivered on a daily update frequency. This dataset is created by downloading data using Binance API.

This dataset is an important companion to the Binance Crypto Future Price Data dataset because it contains information on margin interest data to model margin costs.

For more information about the Binance Crypto Future Margin Rate Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the Binance Crypto Future Margin Rate dataset:

```
PY
def Initialize(self) -> None:
    self.SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin)
    self.SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin)

    self.crypto_future_symbol = self.AddCryptoFuture("BTCBUSD", Resolution.Minute).Symbol
```

The Binance Crypto Future Margin Rate data is added to your algorithm along with the market data when you add a crypto future subscription.

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2020
Asset Coverage	236 Crypto Futures Pairs
Data Density	Regular
Resolution	Daily
Timezone	UTC

Supported Assets

The following table shows the available Crypto Future pairs:

ZILUSDT	ZRXUSDT				

Data Point Attributes

The Binance Crypto Future Margin Rate dataset provides **MarginInterestRate** objects with the following attributes:

Requesting Data

To add Binance Crypto Future Margin Rate data to your algorithm, call the **AddCryptoFuture** method. Save a reference to the Crypto Future **Symbol** so you can access the data later in your algorithm.

```
class CoinAPIDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 6, 1)
        self.SetEndDate(2021, 6, 1)

        # Set Account Currency to Binance Stable Coin for USD
        self.SetAccountCurrency("BUSD")
        self.SetCash(100000)

        self.SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin)
        self.SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin)

        crypto_future = self.AddCryptoFuture("BTCBUSD", Resolution.Minute)
        # perpetual futures does not have a filter function
        self.symbol = crypto_future.Symbol
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Margin Rate data, index the **MarginInterestRates** property of the current **Slice** with the Crypto Future **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.MarginInterestRates:
        interest_rate = slice.MarginInterestRates[self.symbol].InterestRate
        self.Log(f"{self.symbol} close at {slice.Time}: {interest_rate}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for symbol, margin_interest_rate in slice.MarginInterestRates.items():
        interest_rate = margin_interest_rate.InterestRate
        self.Log(f"{symbol} close at {slice.Time}: {interest_rate}")
```

For more information about accessing Crypto Future data, see Handling Data .

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the **AddCrypto** method, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Example Applications

The Binance Crypto Future Margin Rate dataset enables correct margin cost so you can accurately design strategies for Cryptocurrencies with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid cryptocurrencies

QuantConnect

US ETF Constituents

Introduction

The US ETF Constituents dataset by QuantConnect tracks the constituents and weighting of US Equities in 2,650 ETF listings. The data starts in January 2009 and is delivered on a daily basis. This dataset is created by tracking the host ETF websites and can be delayed by up to 1 week.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US ETF Constituents dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 160,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US ETF Constituents dataset:

```
PY
from QuantConnect.DataSource import *

# Use the following method for a Classic Algorithm
self.AddUniverse(self.Universe.ETF("SPY", Market.USA, self.UniverseSettings, self.ETFConstituentsFilter))

symbol = Symbol.Create("SPY", SecurityType.Equity, Market.USA)
# Use the following method for a Framework Algorithm
self.AddUniverseSelection(ETFConstituentsUniverseSelectionModel(symbol, self.UniverseSettings,
self.ETFConstituentsFilter))
```

Data Point Attributes

The ETF Constituents dataset provides **ETFConstituentData** objects, which have the following attributes:

Requesting Data

To add US ETF Constituents data to your algorithm, call the **AddUniverse** and **Universe.ETF** methods.. To select which constituents occupy the universe, provide the ETF **Symbol** and a selection function.

```
class ETFConstituentsDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2018, 1, 1)
        self.SetEndDate(2020, 8, 25)
        self.SetCash(100000)

        self.AddUniverse(self.Universe.ETF("SPY", self.UniverseSettings, self.ETFConstituentsFilter))
```

Accessing Data

To access the US ETF Constituent data, use the **ETFConstituentData** objects in your selection function. The data is available in daily resolution. The **Symbol** objects you return from your selection function defines the universe constituents.

```
PY
def ETFConstituentsFilter(self, constituents: List[ETFConstituentData]) -> List[Symbol]:
    for c in constituents:
        self.Debug(f'{c.EndTime} :: {c.LastUpdate} :: {c.Weight} :: {c.SharesHeld} :: {c.MarketValue}')
    return [x.Symbol for x in constituents]
```

Historical Data

You can't request historical **ETFConstituentData** objects, but you can you can use the **Symbol** member of each object to request historical market data of the securities that the **ETFConstituentData** objects reference. If there is no data in the period you request, the history result is empty.

```
PY
def ETFConstituentsFilter(self, constituents: List[ETFConstituentData]) -> List[Symbol]:
    # Get the 20 largest weighting constituents
    selected = sorted([c for c in constituents if c.Weight],
        key=lambda c: c.Weight, reverse=True)[:20]
    selectedSymbols = [c.Symbol for c in selected]

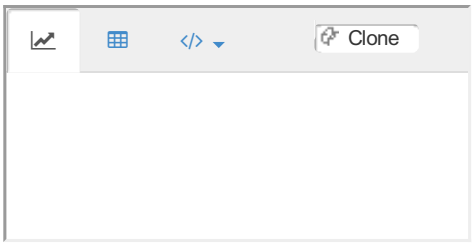
    history = History(selectedSymbols, 10, Resolution.Daily)

    return selectedSymbols
```

Example Applications

The ETF Constituents dataset provides an excellent source of tradable universes for strategies without selection bias. When you use an ETF universe, the original ETF can serve as an excellent benchmark for your strategy performance. Other use cases include the following:

- Creating an index-tracking algorithm for customized passive portfolio management
- Performing statistical arbitrage with the base ETF



Clone

QuantConnect

US Equity Coarse Universe

Introduction

The US Equity Coarse Universe dataset by QuantConnect is a daily universe of all trading stocks in the US for a given day with the end of day price and volume. The data covers 30,000 US Equities in total, with approximately 8,000 Equities per day. The data starts in January 1998 and is delivered each trading day. This dataset is created by taking the closing auction price tick from the daily L1 trade and quote exchange dumps.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Equity Coarse Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Equity Coarse Universe dataset:

```
from QuantConnect.DataSource import *
self.AddUniverse(self.CoarseSelectionFunction)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	30,000 US Equities
Data Density	Dense
Resolution	Daily
Timezone	New York

Data Point Attributes

The US Equity Coarse Universe dataset provides **CoarseFundamental** objects, which have the following attributes:

Requesting Data

To add US Equity Coarse Universe data to your algorithm, call the **AddUniverse** method with a selection function.

```
PY
class USEquityCoarseUniverseConstituentsDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1)
        self.SetEndDate(2021, 7, 1)
        self.SetCash(100000)

        self.AddUniverse(self.CoarseSelectionFunction)
```

Accessing Data

To access US Equity Coarse Universe data, use the **CoarseFundamental** objects in your selection function. The data is available in daily resolution.

```
PY
def CoarseSelectionFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:

    sorted_by_dollar_volume = sorted(coarse, key=lambda x: x.DollarVolume, reverse=True)[:3]
    for cf in sorted_by_dollar_volume:
        self.Debug(f"{cf.EndTime} :: {cf.Symbol} : {cf.AdjustedPrice} :: {cf.DollarVolume}")

    return [ x.Symbol for x in sortedByDollarVolume]
```

Historical Data

You can't request historical **CoarseFundamental** objects, but you can you can use the **Symbol** member of each object to request historical market data of the securities that the **CoarseFundamental** objects reference. If there is no data in the period you request, the history result is empty.

```
PY
def CoarseSelectionFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:

    selected_symbols = [x.Symbol
        for x in sorted(coarse, key=lambda x: x.DollarVolume, reverse=True)[:3]]

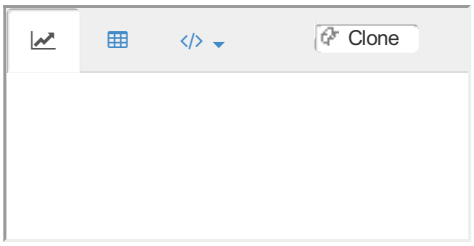
    history = self.History(selected_symbols, 10, Resolution.Daily)

    return selected_symbols
```

Example Applications

The US Security Master dataset enables you to accurately design a universe of US Equities. Examples include the following strategies:

- Selecting securities with the largest dollar volume
- Selecting securities within a specific price range
- Selecting securities that have fundamental data available (requires an additional fine universe selection model)



Clone

QuantConnect

US Equity Security Master

Introduction

The US Equity Security Master dataset by QuantConnect tracks US Equity corporate actions, including splits, dividends, delistings, mergers, and ticker changes through history. The data covers approximately 27,500 US Equities, starts in January 1998, and is delivered on a daily update frequency. You can easily download and install the dataset with the LEAN CLI so it's ready to use by LEAN. LEAN automatically handles all corporate actions and passes them into your algorithm as events .

For more information about the US Equity Security Master dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Data Summary

Data is delivered as a daily updated zip archive of map and factor files. The data is designed to be used in the LEAN Engine and cannot be consumed another way. The following table shows the dataset properties:

Property	Value
Start Date	January 1998
Data Points	Splits, Dividends, Mergers, IPO, & Delistings
Asset Coverage	27,500 US Equities
Resolution	Daily
Timezone	New York

Getting Started

You don't need any special code to utilize the US Equity Security Master. It automatically loads when you request US Equities data .

Supported Assets

To view the supported assets in the US Equity Security Master dataset, see the Data Explorer .

Data Point Attributes

The US Equity Security Master dataset provides **Split** , **Dividend** , **Delisting** , and **SymbolChangedEvent** objects.

Split Attributes

When a split or merger occurs, we pass the previous **Symbol** data into your algorithm. **Split** objects have the following attributes:

Dividend Attributes

Dividend events are triggered on the payment date. **Dividend** objects have the following attributes:

Delisting Attributes

When a security is delisted, we notify your algorithm. **Delisting** objects have the following attributes:

SymbolChangedEvent Attributes

When a security changes their ticker, we notify your algorithm. **SymbolChangedEvent** objects have the following attributes:

Accessing Splits

To get the current split data, index the **Splits** property of the current **Slice** with the Equity **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.Splits.ContainsKey(self.symbol):
        split = slice.Splits[self.symbol]
        split_type = {0: "Warning", 1: "SplitOccurred"}.get(split.Type)
        self.Log(f"Split: {split.Symbol}\t{split.SplitFactor}\t{split.ReferencePrice}\t{split_type}")
```

For more information about accessing splits, see Splits .

Accessing Dividends

To get the current dividend data, index the **Dividends** property of the current **Slice** with the Equity **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.Dividends.ContainsKey(self.symbol):
        dividend = slice.Dividends[self.symbol]
        self.Log(f'Dividend: {dividend.Symbol}\t{dividend.Distribution}\t{dividend.ReferencePrice}')
```

For more information about accessing dividends, see Dividends .

Accessing Delistings

To get the current Delistings data, index the **Delistings** property of the current **Slice** with the Equity **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if slice.Delistings.ContainsKey(self.symbol):
        delisting = slice.Delistings[self.symbol]
        delisting_type = {0: "Warning", 1: "Delisted"}.get(delisting.Type)
        self.Log(f'Delistings: {delisting_type}')
```

For more information about accessing delistings, see Delistings .

Accessing Symbol Change Events

To get the current Symbol change events, index the **SymbolChangedEvents** property of the current **Slice** with the Equity **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

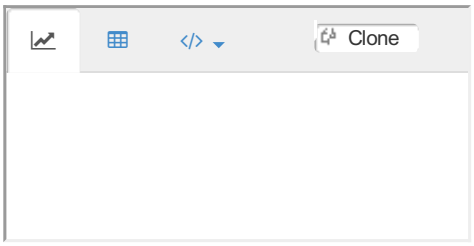
```
def OnData(self, slice: Slice) -> None:
    if slice.SymbolChangedEvents.ContainsKey(self.symbol):
        symbol_changed_event = slice.SymbolChangedEvents[self.symbol]
        self.Log(f"Symbol changed: {symbol_changed_event.OldSymbol} -> {symbol_changed_event.NewSymbol}")
```

For more information about accessing Symbol change events, see Symbol Changes .

Example Applications

The US Security Master enables you to accurately design strategies harnessing any core corporate actions. Examples include the following strategies:

- Post-dividend announcement trading strategies.
- Trading on new Equities by monitoring for IPOs.
- Harnessing split announcements for reverse-split announcement momentum.



QuantConnect

US Futures Security Master

Introduction

The US Futures Security Master dataset by QuantConnect provides mapping reference data for the most liquid contracts of the CME Group exchanges, calculated with popular rolling techniques. The data covers 75 root Future contracts, starts in 2012, and is delivered on a daily frequency with a zip file with all the contract mappings. This dataset is created by daily processing of the US historical Future chains.

This dataset, paired the US Futures dataset, supports the following rolling techniques: ForwardPanamaCanal, BackwardsPanamaCanal, and Backwards Ratio. You can set the specific date of rolling to occur on the LastTradingDay, FirstDayMonth, or on the day where the contract with the greatest OpenInterest changes.

For more information about the US Futures Security Master dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

You don't need any special code to utilize the US Futures Security Master. It automatically loads when you request US Futures data .

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	75 Liquid Futures
Data Density	Regular
Resolution	Daily

Data Point Attributes

The US Futures Security Master dataset provides **SymbolChangedEvent** objects, which have the following attributes:

Key Concept

The US Futures Security Master lets you to construct continuous Futures, allowing the access of normalized historical data of the underlying assets, as well as trading the “lead” Future contracts for those assets.

Continuous Futures refer to sets of rolling lead Future contracts during their actively trading periods. Since Future contracts expire at their maturities, to analyze the historical price of a Future and to apply technical indicators, you need the continuous Future price series.

To access the continuous Future, use the Future's **Symbol** property.

```
PY
future = self.AddFuture(Futures.Energies.CrudeOilWTI,
    dataNormalizationMode = DataNormalizationMode.BackwardsRatio,
    dataMappingMode = DataMappingMode.OpenInterest,
    contractDepthOffset = 0)
self.continuous_contract_symbol = future.Symbol
```

The **dataNormalizationMode** and **dataMappingMode** arguments makes the transition of the underlying contracts seemless. However, the Future **Symbol** doesn't map to an underlying Future contract. It works fine to trade within backtests, but could be subjected to friction costs during live trading since the order price could be a normalized price. For more information about this topic, see the **Live Trading Considerations** section.

Data Normalization Modes

The data normalization mode defines how the price series of two contracts are stitched together when the contract rollovers occur. The **DataNormalizatoinMode** enumeration has the following members available for continuous contracts:

If you use a data normalization mode that's not in the preceding list, LEAN automatically converts it to **DataNormalizationMode.BackwardsRatio** .

Data Mapping Modes

The data mapping mode defines when contract rollovers occur. The **DataMappingMode** enumeration has the following members:

Tracking Contract Changes

As the contracts roll over, the **Mapped** property of the **Future** object references the next contract in the series and you receive a **SymbolChangedEvent** . To get the current **Symbol** change events, index the **SymbolChangedEvents** property of the current **Slice** with the continuous Futures **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your Future at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice)0 -> None:
    if slice.SymbolChangedEvents.ContainsKey(self.continuous_future_symbol):
        symbol_changed_event = slice.SymbolChangedEvents[self.continuous_future_symbol]
        self.Log(f"Symbol changed: {symbolChangedEvent.OldSymbol} -> {symbolChangedEvent.NewSymbol}")
```

SymbolChangedEvent objects have the following attributes:

Live Trading Considerations

You can trade continuous Futures, but the continuous Future **Symbol** doesn't map to a single underlying Future contract. Instead, it represents a set of rolling contracts. Thus, the prices could be frictional during a contract rollover, which could be catastrophic in live trading! For live trading, you should place your orders directly on the underlying contracts. To get the current underlying contract in the continuous Future series, use the **Mapped** property.

```
current_contract = self.continuous_contract.Mapped
self.Buy(current_contract, 1)
```

Data Format

If you download the files in the US Futures Security Master, you get a factor file and a map file for each of the exchanges with supported continuous Futures. To view the files, see the *|data|future|<exchange_name>* directory under your LEAN CLI base directory.

For the factor file, it is a **.zip** collection of REST API styled **.csv** files for each Future **Symbol** , including the date, scaling factors for each type of data normalization and the data mapping mode that indicates the Symbol changing event is on that day for that mapping mode. The following line is an example line in the **.csv** file:

{"Date":"2009-10-31T00:00:00","BackwardsRatioScale":[0.9914163090128755364806866953,1.0,1.0],"BackwardsPanamaCanalScale":[-2.0,0.0,0.0],"ForwardPanamaCanalScale":[0.0,0.0,0.0],"DataMappingMode":1}

For the map file, it is a **.zip** collection of **.csv** files for each Future **Symbol** , including the date , new underlying contract Symbol, the exchange code, and the data mapping mode that indicates the Symbol changing event is on that day for that mapping mode. The following line is an example line in the **.csv** file:

20091130,aw uii3j0m6zbj9,CBOT,1

Example Applications

The US Futures Security Master enables you to design strategies harnessing continuous Futures contracts. Examples include the following strategies:

- Trading cyclical patterns in commodity Futures.
- Buying gold Futures as an inflation hedge with automatic contract roll overs.
- Detecting arbitrage opportunities between index Futures and Equities.

AlgoSeek

US Equities

Introduction

The US Equities dataset by AlgoSeek is survivorship bias-free daily coverage of every stock traded in the US Securities Information Processors (SIP) CTA/UTP feed since 1998. The dataset covers approximately 27,500 securities, starts in January 1998, and is delivered in any resolution from tick to daily. The Data is collected from the full SIP feed via our Equinix co-located servers, including all trades and quotes published to every exchange as well as FINRA. Over-the-Counter (OTC) trades are not included.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Equities dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

AlgoSeek is the default US Equities dataset on QuantConnect. The following snippet demonstrates how to request data from the US Equities dataset:

```
PY
from QuantConnect.DataSource import *
self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	27,500 US Equities
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	New York

Supported Assets

To view the supported assets in the US Equities dataset, see the Data Explorer .

Data Point Attributes

The US Equities dataset provides **TradeBar** , **QuoteBar** , and **Tick** objects.

TradeBar Attributes

TradeBar objects have the following attributes:

QuoteBar Attributes

QuoteBar objects have the following attributes:

Tick Attributes

Tick objects have the following attributes:

Requesting Data

To add US Equities data to your algorithm, call the **AddEquity** method. Save a reference to the Equity **Symbol** so you can access the data later in your algorithm.

```
class USEquityDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2018, 1, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)
        self.symbol = self.AddEquity("AAPL", Resolution.Minute).Symbol
```

PY

For more information about creating US Equity subscriptions, see Requesting Data or US Equity Universes .

Accessing Data

To get the current US Equities data, index the **Bars** , **QuoteBars** , or **Ticks** properties of the current **Slice** with the Equity **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
        self.Log(f"{self.symbol} close at {slice.Time}: {trade_bar.Close}")

    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
        self.Log(f"{self.symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        self.Log(f"{symbol} close at {slice.Time}: {trade_bar.Close}")

    for symbol, quote_bar in slice.QuoteBars.items():
        self.Log(f"{symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing US Equities data, see Handling Data .

Historical Data

To get historical US Equity data, call the **History** method with the Equity **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Daily)

# TradeBar objects
history_trade_bars = self.History[TradeBar](self.symbol, 100, Resolution.Daily)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](self.symbol, 100, Resolution.Minute)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Universe Selection

To select a universe of US Equities, see Equity Universes .

Remove Subscriptions

To unsubscribe from a US Equity that you added with the **AddEquity** method, call the **RemoveSecurity** method.

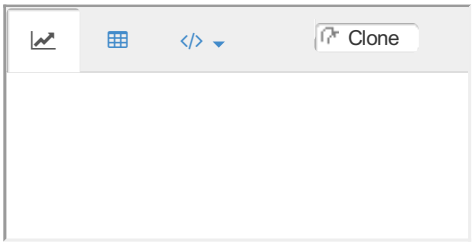
```
self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your holdings.

Example Applications

The US Equities dataset enables you to accurately design Equity trading strategies. Examples include the following strategies:

- Momentum strategies using historical returns on the premise that the momentum will continue
- Value strategies using fundamental factors on the premise that the price of undervalued securities will rise
- Factor investing with periodic rebalancing



AlgoSeek

US Equity Options

Introduction

The US Equity Options data by AlgoSeek provides Option data, including prices, strikes, expires, implied volatility, and Greeks. The data covers 4,000 Symbols, starts in January 2012, and is delivered on a minute frequency. This dataset is created by monitoring Options Price Reporting Authority (OPRA) data feed, which consolidates last sale and quotation information originating from the national securities exchanges that have been approved by the Securities and Exchange Commission.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes of the underlying security.

For more information about the US Equity Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek was in 2014 with the goal of providing the highest quality, most accurate, ready-to-use data in the financial data industry. AlgoSeek provides access to Equities, ETFs, ETNs, Equity Indices, Equity Options, Futures, and Future Options for quantitative firms and traders.

Getting Started

The following snippet demonstrates how to request data from the US Equity Options dataset:

```py
from QuantConnect.DataSource import *

option = self.AddOption("GOOG")
self.option_symbol = option.Symbol
option.SetFilter(-2, +2, 0, 180)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012*
Asset Coverage	4,000 Symbols
Data Density	Dense
Resolution	Minute, Hourly, & Daily
Timezone	New York

* Some data is available before this date. In 2012, AlgoSeek started to fetch data from 48 OPRA channels instead of 24, increasing the quality of the data.

Supported Assets

To view the supported assets in the US Equity Options dataset, see the Data Explorer .

Data Point Attributes

The US Equity Options dataset provides **TradeBar** , **QuoteBar** , and **OpenInterest** objects.

TradeBar Attributes

TradeBar objects have the following attributes:

QuoteBar Attributes

QuoteBar objects have the following attributes:

OpenInterest Attributes

OpenInterest objects have the following attributes:

Requesting Data

To add US Equity Options data to your algorithm, call the **AddOption** method. Save a reference to the Equity Option **Symbol** so you can access the data later in your algorithm.

```
class USEquityOptionsDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 6, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        option = self.AddOption("GOOG")
        self.option_symbol = option.Symbol
        # Set our strike/expiry filter for this option chain
        option.SetFilter(-2, +2, 0, 180)
```

The Equity resolution must be less than or equal to the Equity Option resolution. For example, if you set the Equity resolution to minute, then you must set the Equity Option resolution to minute, hour, or daily.

For more information about creating US Equity Option subscriptions, see Requesting Data or Equity Options Universes .

Accessing Data

To get the current US Equity Options data, index the **OptionChains** property of the current **Slice** with the canonical Equity Option **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your Index Option at every time step. To avoid issues, call the **get** method.

```
def OnData(self, slice: Slice) -> None:
    chain = slice.OptionChains.get(self.option_symbol)
    if chain:
        for contract in chain:
            self.Log(f"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}")
```

You can also iterate through all of the **OptionChain** objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for canonical_symbol, chain in slice.OptionChains.items():
        for contract in chain:
            self.Log(f"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}")
```

For more information about accessing US Equity Options data, see Handling Data .

Historical Data

You can get historical US Equity Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Equity Options data in an algorithm, call the **History** method with the Equity Option contract **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(contract.Symbol, 100, Resolution.Minute)

# TradeBar objects
history_trade_bars = self.History[TradeBar](contract.Symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](contract.Symbol, 100, Resolution.Minute)
```

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Equity Options data in the Research Environment for an entire Option chain, call the **GetOptionHistory** method with the canonical Option **Symbol** .

```
qb = QuantBook()
option = qb.AddOption("GOOG")
option.SetFilter(-2, 2, 0, 90)
history = qb.GetOptionHistory(option.Symbol, datetime(2020, 6, 1), datetime(2020, 6, 5))

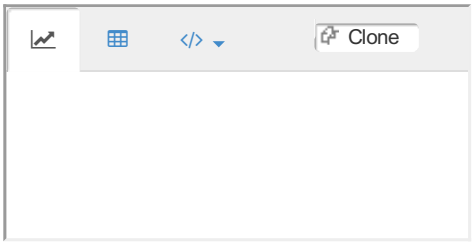
all_history = history.GetAllData()
expiries = history.GetExpiryDates()
strikes = history.GetStrikes()
```

To get historical data for a single US Equity Option contract, call the **History** method like you would in an algorithm but on the **QuantBook** object. For more information about historical data in the Research Environment, see Equity Options .

Example Applications

The US Equity Options dataset enables you to accurately design Option strategies. Examples include the following strategies:

- Buying put Options to hedge against downward price movement in positive Equity positions
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviate from their theoretical value



AlgoSeek

US Future Options

Introduction

The US Future Options dataset by AlgoSeek provides Option data on US Future contracts, including prices, strikes, expires, implied volatility, and Greeks. The data covers 15 Monthly Future contracts, starts in January 2012, and is delivered on a minute frequency. This dataset is created by monitoring the trading activity on the CME, CBOT, NYMEX, and COMEX markets.

For more information about the US Future Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering equities, futures, options, cash forex, and cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Future Options dataset:

```
PY
from QuantConnect.DataSource import *

future = self.AddFuture(Futures.Metals.Gold, Resolution.Minute)
future.SetFilter(0, 90)
self.AddFutureOption(future.Symbol, lambda universe: universe.Strikes(-5, +5))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	15 Monthly Future Contracts
Data Density	Dense
Resolution	Minute, Hourly, & Daily
Timezone	New York

Supported Assets

The following table shows the available Future Options:

Name			
Symbol	**Underlying**	**Market**	**Accessor Code**
Class III Milk Futures			
DC	DC	CME	`Futures.Dairy.ClassIIIMilk`
Crude Oil Futures			
LO	CL	NYMEX	`Futures.Energies.CrudeOilWTI`
NY Harbor ULSD Futures			
OH	HO	NYMEX	`Futures.Energies.HeatingOil`
Henry Hub Natural Gas Futures			
ON	NG	NYMEX	`Futures.Energies.NaturalGas`
RBOB Gasoline Futures			
OB	RB	NYMEX	`Futures.Energies.Gasoline`
U.S. Treasury Bond Futures			
OZB	ZB	CBOT	`Futures.Financials.Y30TreasuryBond`
2-Year T-Note Futures			
OZT	ZT	CBOT	`Futures.Financials.Y2TreasuryNote`
Corn Futures			
OZC	ZC	CBOT	`Futures.Grains.Corn`
Soybean Futures			
OZS	ZS	CBOT	`Futures.Grains.Soybeans`
Chicago SRW Wheat Futures			
OZW	ZW	CBOT	`Futures.Grains.SRWWheat`
E-mini S&P 500 Futures			

Name			
Symbol	**Underlying**	**Market**	**Accessor Code**

OG	GC	COMEX	`Futures.Metals.Gold`
Copper Futures			
HXE	HG	COMEX	`Futures.Metals.Copper`
Silver Futures			
SO	SI	COMEX	`Futures.Metals.Silver`

Data Point Attributes

The US Future Options dataset provides **TradeBar** , **QuoteBar** , and **OpenInterest** objects.

TradeBar Attributes

TradeBar objects have the following attributes:

QuoteBar Attributes

QuoteBar objects have the following attributes:

OpenInterest Attributes

OpenInterest objects have the following attributes:

Requesting Data

To add US Future Options data to your algorithm, call the **AddFutureOption** method.

```
class FutureOptionDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 1, 28)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        future = self.AddFuture(Futures.Metals.Gold, Resolution.Minute)
        future.SetFilter(0, 90)
        self.AddFutureOption(future.Symbol, lambda universe: universe.Strikes(-5, +5))
```

The Future resolution must be less than or equal to the Future Option resolution. For example, if you set the Future

resolution to minute, then the Future Option resolution must be minute, hour, or daily.

For more information about creating Future Options subscriptions, see Requesting Data or Future Options Universes .

Accessing Data

To get the current Future Options data, iterate through the **OptionChains** of the current **Slice** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your Future Options at every time step.

```
PY
def OnData(self, slice: Slice) -> None:
    for canonical_fop_symbol, chain in slice.OptionChains.items():
        for contract in chain:
            self.Log(f"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}")
```

You can also iterate through the **FuturesChains** in the current **Slice** first.

```
PY
def OnData(self, slice: Slice) -> None:
    for continuous_future_symbol, futures_chain in slice.FuturesChains.items():
        # Select a Future Contract and create its canonical FOP Symbol
        futures_contract = [contract for contract in futures_chain][0]
        canonical_fop_symbol = Symbol.CreateCanonicalOption(futures_contract.Symbol)
        option_chain = slice.OptionChains.get(canonical_fop_symbol)
        if option_chain:
            for fop_contract in option_chain:
                self.Log(f"{fop_contract.Symbol} price at {slice.Time}: {fop_contract.LastPrice}")
```

For more information about accessing Future Options data, see Handling Data .

Historical Data

You can get historical US Future Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Options data in an algorithm, call the **History** method with the Future Option contract **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(contract.Symbol, 100, Resolution.Minute)

# TradeBar objects
history_trade_bars = self.History[TradeBar](contract.Symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](contract.Symbol, 100, Resolution.Minute)
```

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Future Options data in the Research Environment for the entire Option chain of a Futures contract, call the **GetOptionHistory** method with the Futures contract **Symbol** .

```
qb = QuantBook()
future = qb.AddFuture(Futures.Indices.SP500EMini, Resolution.Minute)
future_symbols = qb.FutureChainProvider.GetFutureContractList(future.Symbol, datetime(2021, 12, 20))
future_contract_symbol = sorted(future_symbols, key=lambda s: s.ID.Date)[0]

start_time = datetime(2021, 12, 1)
end_time = datetime(2021, 12, 10)
option_history = qb.GetOptionHistory(future_contract_symbol, start_time, end_time, Resolution.Minute)

all_history = option_history.GetAllData()
expiries = option_history.GetExpiryDates()
strikes = option_history.GetStrikes()
```

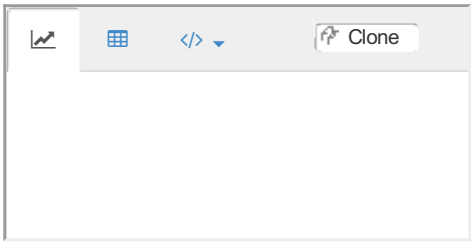
PY

To get historical data for a single US Future Option contract, call the **History** method like you would in an algorithm but on the **QuantBook** object. For more information about historical data in the Research Environment, see Futures Options .

Example Applications

The US Future Options dataset enables you to accurately design Future Option strategies. Examples include the following strategies:

- Selling out of the money Future Option contracts to collect the premium that the Option buyer pays
- Buying put Options to hedge against downward price movement in Future contracts you bought
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviate from their theoretical value



AlgoSeek

US Futures

Introduction

The US Futures dataset by AlgoSeek provides Futures data, including price, volume, open interest, and expiry. The data covers the 75 most liquid contracts, starts in May 2009, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on the CFE, CBOT, NYMEX, ICE*, SGX, India, and COMEX markets.

This dataset does not include ICE Futures, except for Sugar until July 2021.

For more information about the US Futures dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering equities, futures, options, cash forex, and cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Futures dataset:

```
PY
from QuantConnect.DataSource import *

future = self.AddFuture(Futures.Metals.Gold)
future.SetFilter(0, 90)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2009
Asset Coverage	75 Futures
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	• Chicago (CME or CBOT) • New York (NYMEX or COMEX) • Singapore time (SGX) • Indian Standard Time (India)

This dataset includes Sugar ICE Futures until July 2021.

Supported Assets

The following table shows the available Futures:

Name		
Symbol	**Market**	**Accessor Code**
Australian Dollar Futures		
6A	CME	`Futures.Currencies.AUD`
British Pound Futures

Data Point Attributes

The US Futures dataset provides **FuturesChain** , **Future** , and **OpenInterest** objects. To configure the continuous Future settings, use the **DataNormalizationMode** and **DataMappingMode** enumerations.

DataNormalizationMode Values

The **DataNormalizationMode** enumeration has the following values:

DataMappingMode Values

The **DataMappingMode** enumeration has the following values:

Future Attributes

Future objects have the following attributes:

FuturesChain Attributes

FuturesChain objects have the following attributes:

OpenInterest Attributes

OpenInterest objects have the following attributes:

Requesting Data

To add US Futures data to your algorithm, call the **AddFuture** method. Save a reference to the Future so you can access the data later in your algorithm.

```
class USFuturesDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2013, 12, 20)
        self.SetEndDate(2014, 2, 20)
        self.SetCash(1000000)

        future = self.AddFuture(Futures.Metals.Gold)
        future.SetFilter(0, 90)
        self.future_symbol = future.Symbol
```

For more information about creating Future subscriptions, see Requesting Data or Futures Universes .

Accessing Data

To get the current US Futures data, index the **FuturesChains** property of the current **Slice** with the canonical Futures **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your Future at every time step.

```
def OnData(self, slice: Slice) -> None:
    chain = slice.FuturesChains.get(self.future_symbol)
    if chain:
        for contract in chain:
            self.Log(f"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}")
```

You can also iterate through all of the **FuturesChain** objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for canonical_symbol, chain in slice.FuturesChains.items():
        for contract in chain:
            self.Log(f"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}")
```

For more information about accessing Futures data, see Handling Data .

Historical Data

You can get historical US Futures data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Futures data in an algorithm, call the **History** method with the canonical Futures **Symbol** or a Futures contract **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame objects
contract_history_df = self.History(contract.Symbol, 100, Resolution.Minute)
continuous_history_df = self.History(self.future_symbol,
    start=self.Time - timedelta(days=15),
    end=self.Time,
    resolution=Resolution.Minute,
    fillForward=False,
    extendedMarketHours=False,
    dataMappingMode=DataMappingMode.OpenInterest,
    dataNormalizationMode=DataNormalizationMode.Raw,
    contractDepthOffset=0)

# TradeBar objects
contract_history_trade_bars = self.History[TradeBar](contract.Symbol, 100, Resolution.Minute)
continous_history_trade_bars = self.History[TradeBar](self.future_symbol, 100, Resolution.Minute)

# QuoteBar objects
contract_history_quote_bars = self.History[QuoteBar](contract.Symbol, 100, Resolution.Minute)
continous_history_quote_bars = self.History[QuoteBar](self.future_symbol, 100, Resolution.Minute)

# Tick objects
contract_history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
continous_history_ticks = self.History[Tick](self.future_symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data in algorithms, see History Requests . For more information about the price adjustments for continuous contracts, see Continous Contracts .

Historical Data In Research

To get historical US Futures data in the Research Environment for an entire Futures chain, call the **GetFutureHistory** method with the canonical Future **Symbol** .

```
qb = QuantBook()
future = qb.AddFuture(Futures.Metals.Gold)
future.SetFilter(0, 90)
history = qb.GetFutureHistory(future.Symbol, datetime(2020, 6, 1), datetime(2020, 6, 5))

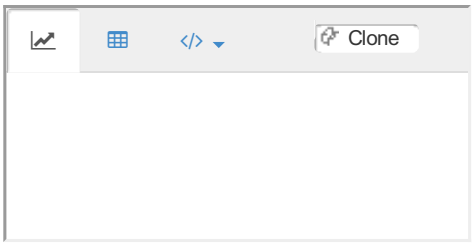
all_history = history.GetAllData()
expiries = history.GetExpiryDates()
```

To get historical data for a single US Futures contract or the continuous Futures contract, call the **History** method like you would in an algorithm but on the **QuantBook** object. For more information about historical data in the Research Environment, see Futures .

Example Applications

The US Futures dataset enables you to accurately design Futures strategies. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trading bull calendar spreads to reduce volatility and margin requirements



Clone

AlgoSeek

US Index Options

Introduction

The US Index Options dataset by AlgoSeek covers European Option contracts for 3 US Indices: SPX, VIX, and NDX. The dataset starts from June 2010 and is delivered on minute resolution. This dataset is created by monitoring the Options Price Reporting Authority (OPRA) data feed, which consolidates last sale and quotation information originating from the national securities exchanges that have been approved by the Securities and Exchange Commission.

For more information about the US Index Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Index Options dataset:

```py
from QuantConnect.DataSource import *

self.index_symbol = self.AddIndex('VIX').Symbol
option = self.AddIndexOption(self.index_symbol)
option.SetFilter(-2, 2, 0, 90)
self.option_symbol = option.Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	June 2010
Asset Coverage	7 Index Options
Data Density	Regular
Resolution	Minute, Hourly, & Daily
Timezone	New York

Supported Assets

The following table shows the available Index Options:

Underlying Index	Underlying Ticker	Target Ticker	Standard Contracts	Weekly Contracts	Tradable on Expiry Day
S&P500	VIX		✓		
S&P500	VIX	VIXW		✓	
S&P500	SPX		✓		
S&P500	SPX	SPXW		✓	✓
NASDAQ-100	NDX		✓		
NASDAQ-100	NDX	NDXP	✓		✓
NASDAQ-100	NDX	NQX	✓	✓	✓

For more information about each underlying Index, see Supported Indices .

Data Point Properties

The US Index Options dataset provides **TradeBar** and **QuoteBar** objects.

TradeBar Attributes

TradeBar objects have the following attributes:

QuoteBar Attributes

QuoteBar objects have the following attributes:

Requesting Data

To add US Index Options data to your algorithm, call the **AddIndexOption** method. Save a reference to the Index Option **Symbol** so you can access the data later in your algorithm.

```
class IndexOptionsDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1);
        self.SetEndDate(2021, 6, 1);
        self.SetCash(1000000);

        self.index_symbol = self.AddIndex('VIX').Symbol

        standard_option = self.AddIndexOption(self.index_symbol)
        standard_option.SetFilter(-2, 2, 0, 90)
        self.standard_option_symbol = standard_option.Symbol

        weekly_option = self.AddIndexOption(self.index_symbol, "VIXW")
        weekly_option.SetFilter(-2, 2, 0, 90)
        self.weekly_option_symbol = weekly_option.Symbol
```

The Index resolution must be less than or equal to the Index Option resolution. For example, if you set the Index resolution to minute, then you must set the Index Option resolution to minute, hour, or daily.

For more information about creating US Index Option subscriptions, see Requesting Data or Index Options Universes .

Accessing Data

To get the current US Index Options data, index the **OptionChains** property of the current **Slice** with the canonical Index Option **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your Index Option at every time step.

```
PY
def OnData(self, slice: Slice) -> None:
    standard_chain = slice.OptionChains.get(self.standard_option_symbol)
    if standard_chain:
        for contract in standard_chain:
            self.Log(f"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}")

    weekly_chain = slice.OptionChains.get(self.weekly_option_symbol)
    if weekly_chain:
        for contract in weekly_chain:
            self.Log(f"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}")
```

You can also iterate through all of the **OptionChain** objects in the current **Slice** .

```
PY
def OnData(self, slice: Slice) -> None:
    for canonical_symbol, chain in slice.OptionChains.items():
        for contract in chain:
            self.Log(f"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}")
```

For more information about accessing US Index Options data, see Handling Data .

Historical Data

You can get historical US Index Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Index Options data in an algorithm, call the **History** method with the Index Option contract **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(contract.Symbol, 100, Resolution.Minute)

# TradeBar objects
history_trade_bars = self.History[TradeBar](contract.Symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](contract.Symbol, 100, Resolution.Minute)
```

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Index Options data in the Research Environment for an entire Option chain, call the

GetOptionHistory method with the canonical Option **Symbol** .

```
qb = QuantBook()
index_symbol = qb.AddIndex('VIX').Symbol
option = qb.AddIndexOption(index_symbol) # or qb.AddIndexOption(index_symbol, "VIXW")
option.SetFilter(-2, 2, 0, 90)
history = qb.GetOptionHistory(option.Symbol, datetime(2020, 6, 1), datetime(2020, 6, 5))

all_history = history.GetAllData()
expiries = history.GetExpiryDates()
strikes = history.GetStrikes()
```

To get historical data for a single US Index Option contract, call the **History** method like you would in an algorithm but on the **QuantBook** object. For more information about historical data in the Research Environment, see Index Options .

Data Point Attributes

The US Index Options dataset provides **TradeBar** and **QuoteBar** objects.

TradeBar Attributes

TradeBar objects have the following attributes:

QuoteBar Attributes

QuoteBar objects have the following attributes:

Example Applications

The US Index Options dataset enables you to accurately design strategies for Index Options. Examples include the following strategies:

- Buying VIX call Options to hedge against upcoming volatility
- Buying VIX put Options to capture the natural downward price movement in the VIX index
- Buying SPX put Options to protect against downward price movement in the S&P 500

Datasets

Morningstar

Morningstar was founded by Joe Mansueto in 1984 with the goal of empowering investors by connecting people to the investing information and tools they need. Morningstar provides access extensive line of products and services for individual investors, financial advisors, asset managers, and retirement plan providers. Morningstar provides data on approximately 525,000 investment offerings including stocks, mutual funds, and similar vehicles, along with real-time global market data on nearly 18 million equities, indexes, futures, options, commodities, and precious metals, in addition to foreign exchange and Treasury markets. Morningstar also offers investment management services through its investment advisory subsidiaries, with $244 billion in assets under advisement or management as of 2021.

US Fundamental Data

Morningstar

US Fundamental Data

Introduction

The US Fundamental Data by Morningstar tracks US Equity fundamentals. The data covers 5,000 US Equities, starts in January 1998, and is delivered on a daily frequency. This dataset is created by using a combination of string matching, Regular Expressions, and Machine Learning to gather the fundamental data published by companies.

For older symbols, the file date is approximated 45 days after the as of date. When a filing date is present on the Morningstar data, it is used. As we are a quant platform, all the data is loaded using "As Original Reported" figures. If there was a mistake reporting the figure, this will not be fixed later. The market typically responds quickly to these initially reported figures. Data is available for multiple periods depending on the property. Periods available include: 1 mo, 2 mo, 3 mo, 6 mo, 9 mo, 12 mo, 1 Yr, 2 Yr, 3 Yr, and 5 Yr. Morningstar symbols cover the NYSE, NASDAQ, AMEX, and BATS exchanges.

In live trading, Morningstar data is delivered to your algorithm at approximately 6 am each day. The majority of the fundamental data update occurs once per month. This includes updates to all of the key information for each security Morningstar supports. On top of this monthly update, there are daily updates of the financial ratios.

As Morningstar data arrives, it updates the master copy and is passed into your algorithm, similar to how TradeBars are fill-forwarded in your data feed. If there have been no updates for a day, you'll receive the same fundamental data.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Fundamental Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Morningstar was founded by Joe Mansueto in 1984 with the goal of empowering investors by connecting people to the investing information and tools they need. Morningstar provides access extensive line of products and services for individual investors, financial advisors, asset managers, and retirement plan providers. Morningstar provides data on approximately 525,000 investment offerings including stocks, mutual funds, and similar vehicles, along with real-time global market data on nearly 18 million equities, indexes, futures, options, commodities, and precious metals, in addition to foreign exchange and Treasury markets. Morningstar also offers investment management services through its investment advisory subsidiaries, with $244 billion in assets under advisement or management as of 2021.

Getting Started

The following snippet demonstrates how to request data from the US Fundamental dataset:

```
from QuantConnect.DataSource import *

self.AddUniverse(self.SelectCoarse, self.SelectFine)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	5,000 US Equities
Corporate Indicators / Tracked Fields	900 Fields
Data Density	Sparse
Resolution	Daily
Timezone	New York

Supported Assets

To view the supported assets in the US Fundamental dataset, see the Data Explorer .

Data Point Attributes

The US Fundamentals dataset provides **FineFundamental** objects. To filter **FineFundamental** objects, you can use the **MorningstarSectorCode** , **MorningstarIndustryGroupCode** , and **MorningstarIndustryCode** enumeration values.

FineFundamental Attributes

FineFundamental objects have the following attributes:

MorningstarSectorCode Enumeration

Sectors are large super categories of data. To access the sector of an Equity, use the **MorningstarSectorCode** property.

```
filtered_fine = [x for x in fine if x.AssetClassification.MorningstarSectorCode ==
MorningstarSectorCode.Technology]
```

The **MorningstarSectorCode** enumeration has the following members:

MorningstarIndustryGroupCode Enumeration

Industry groups are clusters of related industries which tie together. To access the industry group of an Equity, use the **MorningstarIndustryGroupCode** property.

```
filtered_fine = [x for x in fine if x.AssetClassification.MorningstarIndustryGroupCode ==
MorningstarIndustryGroupCode.ApplicationSoftware]
```

The **MorningstarIndustryGroupCode** enumeration has the following members:

MorningstarIndustryCode Enumeration

Industries are the finest level of classification available and are the individual industries according to the Morningstar classification system. To access the industry group of an Equity, use the **MorningstarIndustryCode** property.

```
filtered_fine = [x for x in fine if x.AssetClassification.MorningstarIndustryCode ==
MorningstarIndustryCode.SoftwareApplication]
```

The **MorningstarIndustryCode** enumeration has the following members:

Exchange ID Values

The exchange ID represents the exchange that lists the Equity. To access the exchange ID of an Equity, use the **PrimaryExchangeID** property.

```
filtered_fine = [x for x in fine if x.CompanyReference.PrimaryExchangeID == "NAS"]
```

The exchanges are represented by the following string values:

String Representation	Exchange
NYS	New York Stock Exchange (NYSE)
NAS	NASDAQ
ASE	American Stock Exchange (AMEX)
TSE	Tokyo Stock Exchange
AMS	Amsterdam Internet Exchange
SGO	Santiago Stock Exchange
XMAD	Madrid Stock Exchange
ASX	Australian Securities Exchange
BVMF	B3 (stock exchange)
LON	London Stock Exchange
TKS	Istanbul Stock Exchange Settlement and Custody Bank

String Representation	Exchange
SHG	Shanghai Exchange
LIM	Lima Stock Exchange
FRA	Frankfurt Stock Exchange
JSE	Johannesburg Stock Exchange
MIL	Milan Stock Exchange
TAE	Tel Aviv Stock Exchange
STO	Stockholm Stock Exchange
ETR	Deutsche Boerse Xetra Core
PAR	Paris Stock Exchange
BUE	Buenos Aires Stock Exchange
KRX	Korea Exchange
SWX	SIX Swiss Exchange
PINX	Pink Sheets (OTC)
CSE	Canadian Securities Exchange
PHS	Philippine Stock Exchange
MEX	Mexican Stock Exchange
TAI	Taiwan Stock Exchange
IDX	Indonesia Stock Exchange
OSL	Oslo Stock Exchange
BOG	Colombia Stock Exchange
NSE	National Stock Exchange of India
HEL	Nasdaq Helsinki
MISX	Moscow Exchange
HKG	Hong Kong Stock Exchange
IST	Istanbul Stock Exchange
BOM	Bombay Stock Exchange

String Representation	Exchange
TSX	Toronto Stock Exchange
BRU	Brussels Stock Exchange
BATS	BATS Global Markets
ARCX	NYSE Arca
GREY	Grey Market (OTC)
DUS	Dusseldorf Stock Exchange
BER	Berlin Stock Exchange
ROCO	Taipei Exchange
CNQ	Canadian Trading and Quotation System Inc.
BSP	Bangko Sentral ng Pilipinas
NEOE	NEO Exchange

Requesting Data

To add US Fundamental data to your algorithm, pass a fine universe selection method to the **AddUniverse** or **AddUniverseSelection** method.

```
class MorningStarDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1)
        self.SetEndDate(2021, 7, 1)
        self.SetCash(100000)

        self.AddUniverse(self.SelectCoarse, self.SelectFine)
```

Accessing Data

To access fundamental data, use the **FineFundamental** objects in your second selection function or use the **Fundamental** property of the **Equity** objects in your algorithm. The **Symbol** objects you return from the coarse selection function are the **Symbol** objects that comprise the **FineFundamental** objects in your fine fundamental selection function.

```
def SelectCoarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    selected = [c for c in coarse if c.HasFundamentalData]
    sorted_by_dollar_volume = sorted(selected, key=lambda c: c.DollarVolume, reverse=True)
    return [ c.Symbol for c in sorted_by_dollar_volume[:20] ]

def SelectFine(self, fine: List[FineFundamental]) -> List[Symbol]:
    sorted_by_pe_ratio = sorted(fine, key=lambda f: f.ValuationRatios.PERatio, reverse=True)
    return [ f.Symbol for f in sorted_by_pe_ratio[:5] ]
```

Many of the MorningStar values are **MultiPeriodField** objects. These objects represent a timespan of data, normally either **OneMonth** , **ThreeMonths** , **SixMonths** , or **TwelveMonths** . To view the objects, see the the auto-generated classes in the LEAN GitHub repository.

To access fundamental data outside of your fine fundamental selection function, use the **Fundamental** property of the **Equity** objects in your algorithm.

```
fundamentals = self.Securities[symbol].Fundamentals
```

PY

Historical Data

It's currently only possible to get historical fundamental data from the Research Environment. To get historical data, call the **GetFundamental** method with the Equity **Symbol** , a **FineFundamental** property, a start date, and an end date. If there is no data in the period you request, the history result is empty.

```
history = qb.GetFundamental(symbol, "ValuationRatios.PERatio", datetime(2021, 1, 1), datetime(2021, 7, 1))
```

PY

For more information about historical US Equity fundamental data in the Research Environment, see Equity Fundamental Data .

To be notified when historical fundamental data is available in an algorithm, subscribe to GitHub Issue #4890 .

Example Applications

The US Fundamentals dataset enables you to design strategies harnessing fundamental data points. Examples include the following strategies:

- Ranking a universe of securities by a value factor like the book-to-market ratio and buying a subset of the universe with the best factor ranking
- Using the Morningstar asset classification to target specific industries or to ensure your strategy is diversified across several sectors
- Trading securities that recently performed an IPO

TickData

TickData was founded by a futures broker and a programmer in 1984 as the first company in the world to offer historical tick-by-tick prices on the futures and index markets. TickData provides access to comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cash Indices.

US Cash Indices

TickData

US Cash Indices

Introduction

The US Cash Indices dataset by TickData covers 3 US Indices: SPX, VIX, and NDX. The data starts on various dates from Janunary 1998 and is delivered on any frequency from tick to daily. This dataset is created by TickData negotiating directly with exchanges for their official archive and by partnering with real-time data providers who have direct exchange connections and multiple redundant ticker plants.

For more information about the US Cash Indices dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

TickData was founded by a futures broker and a programmer in 1984 as the first company in the world to offer historical tick-by-tick prices on the futures and index markets. TickData provides access to comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cash Indices.

Getting Started

The following snippet demonstrates how to request data from the US Cash Indices dataset:

```
PY
from QuantConnect.DataSource import *
self.symbol = self.AddIndex("VIX", Resolution.Daily).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998*
Coverage	3 US Indices
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	New York

Supported Indices

The following table shows the available indices:

Ticker	Index	Expiry	Start Date
VIX	S&P500	30 Days	Jul 2003
SPX	S&P500	-	Jan 1998
NDX	NASDAQ-100	-	Jan 1998

VIX - CBOE Volatility Index

The Cboe Volatility Index (VIX) is a real-time index that represents the market's expectations for the relative strength of near-term price changes of the S&P 500 index (SPX). Because it's derived from the prices of SPX index Options with near-term expiration dates, it generates a 30-day forward projection of volatility. Volatility, or how fast prices change, is often seen as a way to gauge market sentiment, and in particular, the degree of fear among market participants.

SPX - S&P 500 Index

The S&P 500 Index, or the Standard & Poor's 500 Index, is a market-capitalization-weighted index of the 500 largest publicly-traded companies in the U.S. It is not an exact list of the top 500 U.S. companies by market capitalization because there are other criteria included in the index. The index is widely regarded as the best gauge of large-cap U.S. Equities.

NDX - Nasdaq 100 Index

The Nasdaq-100 Index is a modified market-capitalization-weighted index composed of securities issued by 100 of the largest non-financial companies listed on the Nasdaq Stock Market (Nasdaq). The index includes companies from various industries except for the financial industry, like commercial and investment banks. These non-financial sectors include retail, biotechnology, industrial, technology, health care, and others.

Data Point Attributes

The US Cash Indices dataset provides **TradeBar** and **Tick** objects.

TradeBar Attributes

TradeBar objects have the following attributes:

Tick Attributes

Tick objects have the following attributes:

Requesting Data

To add US Cash Indices data to your algorithm, call the **AddIndex** method. Save a reference to the Index **Symbol** so you can access the data later in your algorithm.

```
class USCashIndexAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 6, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddIndex("VIX").Symbol
```

For more information about creating Index subscriptions, see Requesting Data .

Accessing Data

To get the current US Cash Indices data, index the **Bars** or **Ticks** properties of the current **Slice** with the Index **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
        self.Log(f"{self.symbol} close at {slice.Time}: {trade_bar.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        self.Log(f"{symbol} close at {slice.Time}: {trade_bar.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing US Index data, see Handling Data .

Historical Data

To get historical US Cash Indices data, call the **History** method with the Index **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Daily)

# TradeBar objects
history_bars = self.History[TradeBar](self.symbol, 100, Resolution.Daily)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a US Index subscription, call the **RemoveSecurity** method.

```py
self.RemoveSecurity(self.symbol)
```

Example Applications

The US Cash Indices enables you to incorporate popular US indicies into your trading algorithms. Examples include the following use cases:

- Exploring the difference between the Index and the ETF that tracks it
- Using these indicies as the underlying asset for US Index Options strategies
- Understanding the stock market's level of expected forward-looking volatility, also known as the "fear index". When the VIX starts moving higher, it is telling you that traders are getting nervous. When the VIX starts moving lower, it is telling you that traders are gaining confidence.

To add Binance Crypto Future Price data to your algorithm, call the **AddCryptoFuture** method. Save a reference to the Crypto Future **Symbol** so you can access the data later in your algorithm.

```
class CoinAPIDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 6, 1)
        self.SetEndDate(2021, 6, 1)

        # Set Account Currency to Binance Stable Coin for USD
        self.SetAccountCurrency("BUSD")
        self.SetCash(100000)

        self.SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin)
        self.SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin)

        crypto_future = self.AddCryptoFuture("BTCBUSD", Resolution.Minute)
        # perpetual futures does not have a filter function
        self.symbol = crypto_future.Symbol
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Future Price data, index the **Bars** , **QuoteBars** , or **Ticks** properties of the current **Slice** with the Crypto Future **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
        self.Log(f"{self.symbol} close at {slice.Time}: {trade_bar.Close}")

    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
        self.Log(f"{self.symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        self.Log(f"{symbol} close at {slice.Time}: {trade_bar.Close}")

    for symbol, quote_bar in slice.QuoteBars.items():
        self.Log(f"{symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Binance Crypto Future Price data, call the **History** method with the Crypto Future **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Daily)

# TradeBar objects
history_trade_bars = self.History[TradeBar](self.symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](self.symbol, 100, Resolution.Minute)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto Future contract that you added with the **AddCryptoFuture** method, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your Crypto Future holdings.

Example Applications

The Binance Crypto Future Price dataset enables you to accurately design strategies for Cryptocurrencies with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid cryptocurrencies

CoinAPI

Binance Crypto Price Data

Introduction

The Binance Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 1,651 Cryptocurrency pairs, starts in July 2017, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Binance.

For more information about the Binance Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Binance Crypto Price dataset:

```
PY
from QuantConnect.DataSource import *
from QuantConnect.Data.UniverseSelection import *

# Binance accepts both Cash and Margin account types only.
self.SetBrokerageModel(BrokerageName.Binance, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.Binance, AccountType.Margin)

self.symbol = self.AddCrypto("BTCBUSD", Resolution.Minute, Market.Binance).Symbol

self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.Binance, self.UniverseSettings,
self.UniverseSelectionFilter))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 2017
Asset Coverage	1,651 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC

Supported Assets

The following table shows the available Cryptocurrency pairs:

Data Point Attributes

The Binance Crypto Price dataset provides **TradeBar** , **QuoteBar** , **Tick** , and **CryptoCoarseFundamental** objects.

TradeBar Attributes

TradeBar objects have the following attributes:

QuoteBar Attributes

QuoteBar objects have the following attributes:

Tick Attributes

Tick objects have the following attributes:

CryptoCoarseFundamental Attributes

CryptoCoarseFundamental objects have the following attributes:

Requesting Data

To add Binance Crypto Price data to your algorithm, call the **AddCrypto** method. Save a reference to the Crypto **Symbol** so you can access the data later in your algorithm.

```
PY

class CoinAPIDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 6, 1)
        self.SetEndDate(2021, 6, 1)

        # Set Account Currency to Binance Stable Coin for USD
        self.SetAccountCurrency("BUSD")
        self.SetCash(100000)

        # Binance accepts both Cash and Margin account types.
        self.SetBrokerageModel(BrokerageName.Binance, AccountType.Margin)

        self.symbol = self.AddCrypto("BTCBUSD", Resolution.Minute, Market.Binance).Symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Price data, index the **Bars** , **QuoteBars** , or **Ticks** properties of the current **Slice** with the Crypto **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY

def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
        self.Log(f"{self.symbol} close at {slice.Time}: {trade_bar.Close}")

    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
        self.Log(f"{self.symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        self.Log(f"{symbol} close at {slice.Time}: {trade_bar.Close}")

    for symbol, quote_bar in slice.QuoteBars.items():
        self.Log(f"{symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Binance Crypto Price data, call the **History** method with the Crypto **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Daily)

# TradeBar objects
history_trade_bars = self.History[TradeBar](self.symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](self.symbol, 100, Resolution.Minute)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Binance Crypto pairs, call the **AddUniverse** method with a **CryptoCoarseFundamentalUniverse** object. A Crypto coarse universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
from QuantConnect.Data.UniverseSelection import *

def Initialize(self) -> None:
    self.SetBrokerageModel(BrokerageName.Binance, AccountType.Margin)
    self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.Binance, self.UniverseSettings,
self.UniverseSelectionFilter))

def UniverseSelectionFilter(self, crypto_coarse: List[CryptoCoarseFundamental]) -> List[Symbol]:
    return [c.Symbol for c in crypto_coarse if c.Volume >= 100 and c.VolumeInUsd > 10000]
```

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the **AddCrypto** method, call the **RemoveSecurity** method.

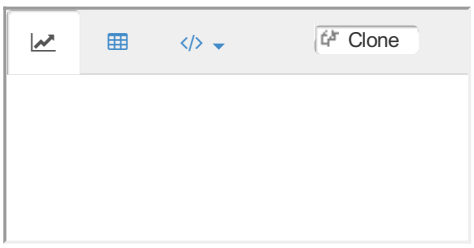
```
self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Example Applications

The Binance Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation



CoinAPI

Binance US Crypto Price Data

Introduction

The Binance US Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 174 Cryptocurrency pairs, starts in October 2019, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Binance US.

For more information about the Binance US Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippets demonstrates how to set the brokerage model, request data, and perform universe selection with the Binance US dataset:

```
PY
from QuantConnect.DataSource import *
from QuantConnect.Data.UniverseSelection import *

# Binance US only accepts cash accounts
self.SetBrokerageModel(BrokerageName.BinanceUS, AccountType.Cash)

self.symbol = self.AddCrypto("BTCUSD", Resolution.Minute, Market.BinanceUS).Symbol

self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.BinanceUS, self.UniverseSettings,
self.UniverseSelectionFilter))
```

Data Summary

Data Point Attributes

The Bitfinex Crypto Price dataset provides **TradeBar** , **QuoteBar** , **Tick** , and **CryptoCoarseFundamental** objects.

TradeBar Attributes

TradeBar objects have the following attributes:

QuoteBar Attributes

QuoteBar objects have the following attributes:

Tick Attributes

Tick objects have the following attributes:

CryptoCoarseFundamental Attributes

CryptoCoarseFundamental objects have the following attributes:

Requesting Data

To add Bitfinex Crypto Price data to your algorithm, call the **AddCrypto** method. Save a reference to the Crypto **Symbol** so you can access the data later in your algorithm.

```
class CoinAPIDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 6, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        # Bitfinex accepts both Cash and Margin type account.
        self.SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin)

        self.symbol = self.AddCrypto("BTCUSD", Resolution.Minute, Market.Bitfinex).Symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Bitfinex Crypto Price data, index the **Bars** , **QuoteBars** , or **Ticks** properties of the current **Slice** with the Crypto **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
        self.Log(f"{self.symbol} close at {slice.Time}: {trade_bar.Close}")

    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
        self.Log(f"{self.symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        self.Log(f"{symbol} close at {slice.Time}: {trade_bar.Close}")

    for symbol, quote_bar in slice.QuoteBars.items():
        self.Log(f"{symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Bitfinex Crypto Price data, call the **History** method with the Crypto **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Daily)

# TradeBar objects
history_trade_bars = self.History[TradeBar](self.symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](self.symbol, 100, Resolution.Minute)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Bitfinex Crypto pairs, call the **AddUniverse** method with a **CryptoCoarseFundamentalUniverse** object. A Crypto coarse universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```py
from QuantConnect.Data.UniverseSelection import *

def Initialize(self) -> None:
    self.SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin)
    self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.Kraken, self.UniverseSettings,
self.UniverseSelectionFilter))

def UniverseSelectionFilter(self, crypto_coarse: List[CryptoCoarseFundamental]) -> List[Symbol]:
    return [c.Symbol for c in crypto_coarse if c.Volume >= 100 and c.VolumeInUsd > 10000]
```

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the **AddCrypto** method, call the **RemoveSecurity** method.

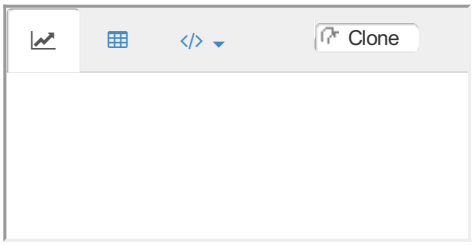
```py
self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Example Applications

The Bitfinex Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation



CoinAPI

Coinbase Crypto Price Data

Introduction

The Coinbase Crypto Price Data by CoinAPI provides Cryptocurrency price and volume data points. The data covers 101 Cryptocurrency pairs, starts in January 2015, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Coinbase.

For more information about the Coinbase Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Coinbase Crypto Price dataset:

```
PY
from QuantConnect.DataSource import *
from QuantConnect.Data.UniverseSelection import *

# Coinbase only accepts Cash account type
self.SetBrokerageModel(BrokerageName.GDAX, AccountType.Cash)

self.symbol = self.AddCrypto("BTCUSD", Resolution.Minute, Market.GDAX).Symbol

self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.GDAX, self.UniverseSettings,
self.UniverseSelectionFilter))
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2015
Asset Coverage	101 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC

Supported Assets

The following table shows the available Cryptocurrency pairs:

Requesting Data

To add Coinbase Crypto Price data to your algorithm, call the **AddCrypto** method. Save a reference to the Crypto **Symbol** so you can access the data later in your algorithm.

```
PY
class CoinAPIDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 6, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        # Coinbase accepts Cash account type only, AccountType.Margin will result in an exception.
        self.SetBrokerageModel(BrokerageName.GDAX, AccountType.Cash)

        self.symbol = self.AddCrypto("BTCUSD", Resolution.Minute, Market.GDAX).Symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Coinbase Crypto Price data, index the **Bars** , **QuoteBars** , or **Ticks** properties of the current **Slice** with the Crypto **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
        self.Log(f"{self.symbol} close at {slice.Time}: {trade_bar.Close}")

    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
        self.Log(f"{self.symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
PY
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        self.Log(f"{symbol} close at {slice.Time}: {trade_bar.Close}")

    for symbol, quote_bar in slice.QuoteBars.items():
        self.Log(f"{symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Coinbase Crypto Price data, call the **History** method with the Crypto **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY

# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Daily)

# TradeBar objects
history_trade_bars = self.History[TradeBar](self.symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](self.symbol, 100, Resolution.Minute)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Coinbase Crypto pairs, call the **AddUniverse** method with a **CryptoCoarseFundamentalUniverse** object. A Crypto coarse universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
PY

from QuantConnect.Data.UniverseSelection import *

def Initialize(self) -> None:
    self.SetBrokerageModel(BrokerageName.GDAX, AccountType.Cash)
    self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.GDAX, self.UniverseSettings,
self.UniverseSelectionFilter))

def UniverseSelectionFilter(self, crypto_coarse: List[CryptoCoarseFundamental]) -> List[Symbol]:
    return [c.Symbol for c in crypto_coarse if c.Volume >= 100 and c.VolumeInUsd > 10000]
```

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the **AddCrypto** method, call the **RemoveSecurity** method.

```
PY

self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Example Applications

The Coinbase Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Requesting Data

To add Kraken Crypto Price data to your algorithm, call the **AddCrypto** method. Save a reference to the Crypto **Symbol** so you can access the data later in your algorithm.

```
class CoinAPIDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 6, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        # Kraken accepts both Cash and Margin type account.
        self.SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin)

        self.symbol = self.AddCrypto("BTCUSD", Resolution.Minute, Market.Kraken).Symbol
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Kraken Crypto Price data, index the **Bars** , **QuoteBars** , or **Ticks** properties of the current **Slice** with the Crypto **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        trade_bar = slice.Bars[self.symbol]
        self.Log(f"{self.symbol} close at {slice.Time}: {trade_bar.Close}")

    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
        self.Log(f"{self.symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
def OnData(self, slice: Slice) -> None:
    for symbol, trade_bar in slice.Bars.items():
        self.Log(f"{symbol} close at {slice.Time}: {trade_bar.Close}")

    for symbol, quote_bar in slice.QuoteBars.items():
        self.Log(f"{symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Kraken Crypto Price data, call the **History** method with the Crypto **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Daily)

# TradeBar objects
history_trade_bars = self.History[TradeBar](self.symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](self.symbol, 100, Resolution.Minute)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Kraken Crypto pairs, call the **AddUniverse** method with a **CryptoCoarseFundamentalUniverse** object. A Crypto coarse universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
from QuantConnect.Data.UniverseSelection import *

def Initialize(self) -> None:
    self.SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin)
    self.AddUniverse(CryptoCoarseFundamentalUniverse(Market.Kraken, self.UniverseSettings,
self.UniverseSelectionFilter))

def UniverseSelectionFilter(self, crypto_coarse: List[CryptoCoarseFundamental]) -> List[Symbol]:
    return [c.Symbol for c in crypto_coarse if c.Volume >= 100 and c.VolumeInUsd > 10000]
```

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the **AddCrypto** method, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Example Applications

The Kraken Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

OANDA

OANDA was co-founded by Dr. Stumm, a computer scientist and Dr. Olsen, an economist, in 1997. The company was born out of the belief that the Internet and technology would open up the markets for both currency data and trading. OANDA uses innovative computer and financial technology to provide Internet-based forex trading and currency information services to everyone, from individuals to large corporations, from portfolio managers to financial institutions. OANDA is a market maker and a trusted source for currency data. It has access to one of the world"s largest historical, high-frequency, filtered currency databases.

CFD Data

Introduction

The CFD Data by OANDA serves 269 contracts for differences (CFD). The data starts as early as May 2002 and is delivered on any frequency from tick to daily. This dataset is created by QuantConnect processing raw tick data from OANDA.

For more information about the CFD Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

OANDA was co-founded by Dr. Stumm, a computer scientist and Dr. Olsen, an economist, in 1997. The company was born out of the belief that the Internet and technology would open up the markets for both currency data and trading. OANDA uses innovative computer and financial technology to provide Internet-based forex trading and currency information services to everyone, from individuals to large corporations, from portfolio managers to financial institutions. OANDA is a market maker and a trusted source for currency data. It has access to one of the world's largest historical, high-frequency, filtered currency databases.

Getting Started

The following snippet demonstrates how to request data from the CFD dataset:

```
PY
from QuantConnect.DataSource import *
self.symbol = self.AddCfd("XAUUSD", Resolution.Daily).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	Mixed, earliest starts May 2002
Asset Coverage	269 Contracts
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	Mixed, in which the contract is listed*

* E.g.: DE30EUR tracks DAX30 Index, which is listed in Europe/Berlin timezone.

Supported Assets

The following table shows the available contracts:

Contracts					
AU200AUD	BCOUSD	CH20AUD	CH20CAD	CH20CHF	CH20EUR
CH20GBP	CH20HKD	CH20JPY	CH20SGD	CH20USD	CNHUSD

Data Point Attributes

The CFD dataset provides **QuoteBar** and **Tick** objects.

QuoteBar Attributes

QuoteBar objects have the following attributes:

Tick Attributes

Tick objects have the following attributes:

Requesting Data

To add CFD data to your algorithm, call the **AddCfd** method. Save a reference to the CFD **Symbol** so you can access the data later in your algorithm.

```
PY
class CfdAlgorithm (QCAlgorithm):
    def Initialize(self) -> None:
        self.SetAccountCurrency('EUR');

        self.SetStartDate(2019, 2, 20)
        self.SetEndDate(2019, 2, 21)
        self.SetCash('EUR', 100000)

        self.symbol = self.AddCfd('DE30EUR').Symbol

        self.SetBenchmark(self.symbol)
```

For more information about creating CFD subscriptions, see Requesting Data .

Accessing Data

To get the current CFD data, index the **QuoteBars** or **Ticks** properties of the current **Slice** with the CFD **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
        self.Log(f"{self.symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
PY
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        self.Log(f"{symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing CFD data, see Handling Data .

Historical Data

To get historical CFD data, call the **History** method with the CFD **Symbol** . If there is no data in the period you request, the history result is empty.

```py
# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](self.symbol, 100, Resolution.Minute)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a CFD subscription, call the **RemoveSecurity** method.

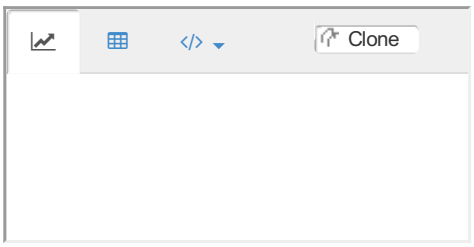
```py
self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your holdings.

Example Applications

The CFD price data enables you to trade CFD assets in your algorithm. Examples include the following strategies:

- Exploring the daily worldwide news cycles with CFDs that track international indices.
- Trading price movements of commodities with no delivery of physical goods. For example, pairs trading between gold and silver, corn and wheat, brent and crude oil, etc.



OANDA

FOREX Data

Introduction

The FOREX Data by OANDA serves 185 foreign exchange (FOREX) pairs, starts on various dates from January 2007, and is delivered on any frequency from tick to daily. This dataset is created by QuantConnect processing raw tick data from OANDA.

For more information about the FOREX Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

OANDA was co-founded by Dr. Stumm, a computer scientist and Dr. Olsen, an economist, in 1997. The company was born out of the belief that the Internet and technology would open up the markets for both currency data and trading. OANDA uses innovative computer and financial technology to provide Internet-based forex trading and currency information services to everyone, from individuals to large corporations, from portfolio managers to financial institutions. OANDA is a market maker and a trusted source for currency data. It has access to one of the world's largest historical, high-frequency, filtered currency databases.

Getting Started

The following snippet demonstrates how to request data from the FOREX dataset:

```
PY
from QuantConnect.DataSource import *
self.symbol = self.AddForex("EURUSD", Resolution.Daily, Market.Oanda).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2007
Asset Coverage	71 Currency pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	UTC

Supported Assets

The following table shows the available Forex pairs:

Forex Pairs					
AUDCAD	AUDCHF	AUDHKD	AUDJPY	AUDNZD	AUDSGD
AUDUSD	CADCHF	CADHKD	CADJPY	CADSGD	CHFHKD
CHFJPY	CHFZAR	EURAUD	EURCAD	EURCHF	EURCZK
EURDKK	EURGBP	EURHKD	EURHUF	EURJPY	EURNOK

USDJPY	USDMXN	USDNOK	USDPLN	USDSAR	USDSEK
USDSGD	USDTHB	USDTRY	USDZAR	ZARJPY	

Data Point Attributes

The FOREX dataset provides **QuoteBar** and **Tick** objects.

QuoteBar Attributes

QuoteBar objects have the following attributes:

Tick Attributes

Tick objects have the following attributes:

Requesting Data

To add FOREX data to your algorithm, call the **AddForex** method. Save a reference to the Forex **Symbol** so you can access the data later in your algorithm.

```
class ForexAlgorithm (QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 2, 20)
        self.SetEndDate(2019, 2, 21)
        self.SetCash(100000)

        self.symbol = self.AddForex('EURUSD', Resolution.Minute, Market.Oanda).Symbol

        self.SetBenchmark(self.symbol)
```

PY

For more information about creating Forex subscriptions, see Requesting Data .

Accessing Data

To get the current Forex data, index the **QuoteBars** or **Ticks** properties of the current **Slice** with the Forex **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your security at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.QuoteBars:
        quote_bar = slice.QuoteBars[self.symbol]
        self.Log(f"{self.symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    if self.symbol in slice.Ticks:
        ticks = slice.Ticks[self.symbol]
        for tick in ticks:
            self.Log(f"{self.symbol} price at {slice.Time}: {tick.Price}")
```

You can also iterate through all of the data objects in the current **Slice** .

```
PY
def OnData(self, slice: Slice) -> None:
    for symbol, quote_bar in slice.QuoteBars.items():
        self.Log(f"{symbol} bid at {slice.Time}: {quote_bar.Bid.Close}")

    for symbol, ticks in slice.Ticks.items():
        for tick in ticks:
            self.Log(f"{symbol} price at {slice.Time}: {tick.Price}")
```

For more information about accessing Forex data, see Handling Data .

Historical Data

To get historical Forex data, call the **History** method with the Forex **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(self.symbol, 100, Resolution.Minute)

# QuoteBar objects
history_quote_bars = self.History[QuoteBar](self.symbol, 100, Resolution.Minute)

# Tick objects
history_ticks = self.History[Tick](self.symbol, timedelta(seconds=10), Resolution.Tick)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a Forex pair subscription, call the **RemoveSecurity** method.

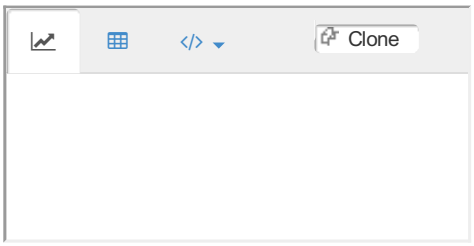
```
PY
self.RemoveSecurity(self.symbol)
```

The **RemoveSecurity** method cancels your open orders for the security and liquidates your holdings.

Example Applications

The FOREX price data enables you to trade currency pairs in the global mark. Examples include the following strategies:

- Exploring the impact that daily worldwide news cycles has on international currencies
- Carry Trade: borrow from a lower interest currency pair to fund the purchase of a currency pair with a higher interest rate



Datasets

Benzinga

Benzinga was founded by Jason Raznick in 2010 with goal of connecting the world with news, data, and education that makes the path to financial prosperity easier for everyone, everyday. Benzinga provides access to real-time news for individual investors.

Benzinga News Feed

Benzinga

Benzinga News Feed

Introduction

The Benzinga News Feed dataset by Benzinga tracks US Equity news releases. The data covers about 1,250 articles per day across 8,000 Equities, starts in January 2016, and is delivered on a second frequency. This dataset is created by structuring the content produced by Benzinga's editorial team.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Benzinga News Feed dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Benzinga was founded by Jason Raznick in 2010 with goal of connecting the world with news, data, and education that makes the path to financial prosperity easier for everyone, everyday. Benzinga provides access to real-time news for individual investors.

Getting Started

The following snippet demonstrates how to request data from the Benzinga News Feed dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(BenzingaNews, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	September 2017
Asset Coverage	8,000 Equities
Data Density	Sparse
Resolution	Second (1,250 Articles/Day)
Timezone	New York

Data Point Attributes

The Benzinga News Feed dataset provides **BenzingaNews** objects, which have the following attributes:

Requesting Data

To add Benzinga News Feed data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY

class BenzingaNewsDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Minute).Symbol
        self.dataset_symbol = self.AddData(BenzingaNews, self.symbol).Symbol
```

Accessing Data

To get the current Benzinga News Feed data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY

def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        article = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} title at {slice.Time}: {article.Title}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY

def OnData(self, slice: Slice) -> None:
    for dataset_symbol, article in slice.Get(BenzingaNews).items():
        self.Log(f"{dataset_symbol} title at {slice.Time}: {article.Title}")
```

Historical Data

To get historical Benzinga News Feed data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY

# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[BenzingaNews](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

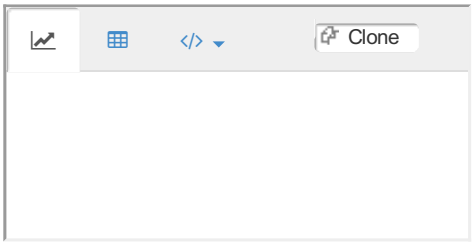
```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Benzinga News Feed data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Benzinga News Feed enables you to accurately design strategies harnessing real-time news releases. Examples include the following strategies:

- Creating a dictionary of sentiment scores for various words and assigning a sentiment score to the content of each news release
- Calculating the sentiment of news releases with Natural Language Processing (NLP)
- Trading securities when their news releases that Benzinga tags with current buzzwords



Datasets

Blockchain

Blockchain is a website that publishes data related to Bitcoin. It has been online since 2011 and publishes the Bitcoin Metadata history back to 2009.

Bitcoin Metadata

Blockchain

Bitcoin Metadata

Introduction

The Bitcoin Metadata dataset by Blockchain provides 23 fundamental metadata of Bitcoin directly fetched from the Bitcoin blockchain. The data starts in January 2009 and delivered on a daily frequency. This dataset contains mining statistics like hash rate and miner revenue; transaction metadata like transaction per block, transaction fee, and number of addresses; and blockchain metadata like blockchain size and block size.

For more information about the Bitcoin Metadata dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Blockchain is a website that publishes data related to Bitcoin. It has been online since 2011 and publishes the Bitcoin Metadata history back to 2009.

Getting Started

The following snippet demonstrates how to request data from the Bitcoin Metadata dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddCrypto("BTCUSD", Resolution.Daily, Market.Bitfinex).Symbol
self.dataset_symbol = self.AddData(BitcoinMetadata, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2009
Coverage	Bitcoin blockchain
Data Density	Regular
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Bitcoin Metadata dataset provides **BitcoinMetadata** objects, which have the following attributes:

Requesting Data

To add Bitcoin Metadata data to your algorithm, call the **AddData** method with the BTCUSD **Symbol** . Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY

class BlockchainBitcoinMetadataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddCrypto("BTCUSD", Resolution.Daily, Market.Bitfinex).Symbol
        self.dataset_symbol = self.AddData(BitcoinMetadata, self.symbol).Symbol
```

Accessing Data

To get the current Bitcoin Metadata data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY

def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} miner revenue at {slice.Time}: {data_point.MinersRevenue}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY

def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(BlockchainBitcoinData).items():
        self.Log(f"{dataset_symbol} miner revenue at {slice.Time}: {data_point.MinersRevenue}")
```

Historical Data

To get historical Bitcoin Metadata data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY

# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[BlockchainBitcoinData](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
PY

self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The Bitcoin Metadata dataset enables you to incorporate metadata from the Bitcoin blockchain into your strategies. Examples include the following strategies:

- Comparing mining and transaction statistics to provide insight on the supply-demand relationship of the Bitcoin blockchain service.
- Measuring the activity and popularity of the Bitcoin blockchain to predict the price movements of the Cryptocurrency.

Brain Language Metrics on Company Filings

Introduction

The Brain Language Metrics on Company Filings dataset provides the results of an NLP system that monitors several language metrics on 10-K and 10-Q company reports for US Equities. The data covers 5,000 US Equities, starts in January 2010, and is delivered on a daily frequency. The dataset is made of two parts; the first one includes the language metrics of the most recent 10-K or 10-Q report for each firm, namely:

1. Financial sentiment
2. Percentage of words belonging to financial domain classified by language types (e.g. “litigious” or “constraining” language)
3. Readability score
4. Lexical metrics such as lexical density and richness
5. Text statistics such as the report length and the average sentence length

The second part includes the differences between the two most recent 10-Ks or 10-Qs reports of the same period for each company, namely:

1. Difference of the various language metrics (e.g. delta sentiment, delta readability score, delta percentage of a specific language type etc.)
2. Similarity metrics between documents, also with respect to a specific language type (for example similarity with respect to “litigious” language or “uncertainty” language)

The analysis is available for the whole report and for specific sections of the report (e.g. Risk Factors and MD&A).

For more information, refer to Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain Language Metrics on Company Filings dataset, including CLI commands and pricing, see the dataset listing .

        data_point = slice[self.dataset_10k_symbol]
        self.Log(f"{self.dataset_10k_symbol} report sentiment at {slice.Time}:
{data_point.ReportSentiment.Sentiment}")

    if slice.ContainsKey(self.dataset_all_symbol):
        data_point = slice[self.dataset_all_symbol]
        self.Log(f"{self.dataset_all_symbol} report sentiment at {slice.Time}:
{data_point.ReportSentiment.Sentiment}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY

def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(BrainCompanyFilingLanguageMetrics10K).items():
        self.Log(f"{dataset_symbol} report sentiment at {slice.Time}:
{data_point.ReportSentiment.Sentiment}")

    for dataset_symbol, data_point in slice.Get(BrainCompanyFilingLanguageMetricsAll).items():
        self.Log(f"{dataset_symbol} report sentiment at {slice.Time}:
{data_point.ReportSentiment.Sentiment}")
```

Historical Data

To get historical Brain Language Metrics on Company Filings data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY

# DataFrames
ten_k_history_df = self.History(self.dataset_10k_symbol, 100, Resolution.Daily)
all_history_df = self.History(self.dataset_all_symbol, 100, Resolution.Daily)
history_df = self.History([self.dataset_10k_symbol, self.dataset_all_symbol], 100, Resolution.Daily)

# Dataset objects
ten_k_history_bars = self.History[BrainCompanyFilingLanguageMetrics10K](self.dataset_10k_symbol, 100,
Resolution.Daily)
all_history_bars = self.History[BrainCompanyFilingLanguageMetricsAll](self.dataset_all_symbol, 100,
Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain Language Metrics on Company Filings data, call the **AddUniverse** method with the **BrainCompanyFilingLanguageMetricsUniverseAll** class or the **BrainCompanyFilingLanguageMetricsUniverse10K** class and a selection function.

```
PY
def Initialize(self) -> None:
    self.AddUniverse(BrainCompanyFilingLanguageMetricsUniverseAll,
"BrainCompanyFilingLanguageMetricsUniverseAll", Resolution.Daily, self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[BrainCompanyFilingLanguageMetricsUniverseAll]) ->
List[Symbol]:
    return [d.Symbol for d in alt_coarse \
                if d.ReportSentiment.Sentiment > 0 \
                and d.ManagementDiscussionAnalyasisOfFinancialConditionAndResultsOfOperations.Sentiment >
0]
```

For more information about dynamic universes, see Universes .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
PY
self.RemoveSecurity(self.dataset_10k_symbol)
self.RemoveSecurity(self.dataset_all_symbol)
```

If you subscribe to Brain Language Metrics on Company Filings data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Brain Language Metrics on Company Filings dataset enables you to test strategies using language metrics and their differences gathered from 10K and 10Q reports. Examples include the following strategies:

- Using the similarity among reports to determine position sizing of securities. Some examples are discussed in Lazy Prices, Cohen et al. 2018 and The Positive Similarity of Company Filings and the Cross-section of Stock Returns, M. Padyšák 2020 .
- Using the sentiment of the latest report to determine the portfolio allocation to give to each security in the universe.
- Using levels of uncertainty, readability, or litigious language in the report to determine position sizing of securities.

Disclaimer: The dataset is provided by the data provider for informational purposes only and does not constitute an offer to sell, a solicitation to buy, or a recommendation or endorsement for any security or strategy, nor do they constitute an offer to provide investment advisory or other services by the data provider.

Brain

Brain ML Stock Ranking

Introduction

The Brain ML Stock Ranking dataset by Brain generates a daily ranking for US Equities based on their predicted ranking of future returns relative to the universe median across four-time horizons: next 2, 3, 5, 10, and 21 days (one trading month). The data covers 1,000 US Equities (universe updated yearly by including the largest 1,000 US companies of the previous year), starts in January 2010, and is delivered on a daily frequency. This dataset is created by a voting scheme of machine learning classifiers that non-linearly combine a variety of features with a series of techniques aimed at mitigating the well-known overfitting problem for financial data with a low signal-to-noise ratio. Examples of features are time-varying stock-specific features like price and volume-related metrics or fundamentals; time-fixed stock-specific features like the sector and other database information; market regime features such as volatility and other financial stress indicators; calendar features representing possible anomalies, for example, the month of the year.

More precisely the ML Stock Ranking score is related to the confidence of a Machine Learning classifier in predicting top or bottom quintile returns for the next N trading days (e.g. next 21 trading days) for a stock with the respect to the median of the universe and ranges from -1 to +1.

A negative score means that the system is more confident that the stock belongs to the lower returns quintile, a positive score means that the system is more confident that the stock belongs to the higher returns quintile. It is important to note that the score has a meaning only if used to compare different stocks to perform a ranking.

Typical use is to download the score for a large stock universe for a given day, e.g. 500 stocks or the full universe of 1000 stocks, order the stocks by mlAlpha score and go long the top K stocks, or build a long-short strategy going long the top K and short the bottom K stocks.

For more information, refer to Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain ML Stock Ranking dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain ML Stock Ranking dataset:

```
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(BrainStockRanking2Day, self.symbol).Symbol

self.AddUniverse(BrainStockRankingUniverse, "BrainStockRankingUniverse", Resolution.Daily,
self.UniverseSelectionMethod)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2010
Asset Coverage	1,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Brain ML Stock Ranking dataset provides **BrainStockRankingBase** and **BrainStockRankingUniverse** objects.

BrainStockRankingBase Attributes

BrainStockRankingBase objects have the following attributes:

BrainStockRankingUniverse Attributes

BrainStockRankingUniverse objects have the following attributes:

Requesting Data

To add Brain ML Stock Ranking data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
class BrainMLRankingDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1)
        self.SetEndDate(2021, 7, 8)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.two_day_symbol = self.AddData(BrainStockRanking2Day, self.symbol).Symbol
        self.three_day_symbol = self.AddData(BrainStockRanking3Day, self.symbol).Symbol
        self.five_day_symbol = self.AddData(BrainStockRanking5Day, self.symbol).Symbol
        self.ten_day_symbol = self.AddData(BrainStockRanking10Day, self.symbol).Symbol
        self.month_symbol = self.AddData(BrainStockRanking21Day, self.symbol).Symbol
```

Accessing Data

To get the current Brain ML Stock Ranking data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.two_day_symbol):
        data_point = slice[self.two_day_symbol]
        self.Log(f"{self.two_day_symbol} rank at {slice.Time}: {data_point.Rank}")

    if slice.ContainsKey(self.three_day_symbol):
        data_point = slice[self.three_day_symbol]
        self.Log(f"{self.three_day_symbol} rank at {slice.Time}: {data_point.Rank}")

    if slice.ContainsKey(self.five_day_symbol):
        data_point = slice[self.five_day_symbol]
        self.Log(f"{self.five_day_symbol} rank at {slice.Time}: {data_point.Rank}")

    if slice.ContainsKey(self.ten_day_symbol):
        data_point = slice[self.ten_day_symbol]
        self.Log(f"{self.ten_day_symbol} rank at {slice.Time}: {data_point.Rank}")

    if slice.ContainsKey(self.month_symbol):
        data_point = slice[self.month_symbol]
        self.Log(f"{self.month_symbol} rank at {slice.Time}: {data_point.Rank}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(BrainStockRanking2Day).items():
        self.Log(f"{dataset_symbol} rank at {slice.Time}: {data_point.Rank}")

    for dataset_symbol, data_point in slice.Get(BrainStockRanking3Day).items():
        self.Log(f"{dataset_symbol} rank at {slice.Time}: {data_point.Rank}")

    for dataset_symbol, data_point in slice.Get(BrainStockRanking5Day).items():
        self.Log(f"{dataset_symbol} rank at {slice.Time}: {data_point.Rank}")

    for dataset_symbol, data_point in slice.Get(BrainStockRanking10Day).items():
        self.Log(f"{dataset_symbol} rank at {slice.Time}: {data_point.Rank}")

    for dataset_symbol, data_point in slice.Get(BrainStockRanking21Day).items():
        self.Log(f"{dataset_symbol} rank at {slice.Time}: {data_point.Rank}")
```

Historical Data

To get historical Brain ML Stock Ranking data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrames
two_day_history_df = self.History(self.two_day_symbol, 100, Resolution.Daily)
three_day_history_df = self.History(self.three_day_symbol, 100, Resolution.Daily)
five_day_history_df = self.History(self.five_day_symbol, 100, Resolution.Daily)
ten_day_history_df = self.History(self.ten_day_symbol, 100, Resolution.Daily)
thirty_day_history_df = self.History(self.month_symbol, 100, Resolution.Daily)
history_df = self.History([self.two_day_symbol,
                           self.three_day_symbol,
                           self.five_day_symbol,
                           self.ten_day_symbol,
                           self.month_symbol], 100, Resolution.Daily)

# Dataset objects
two_day_history_bars = self.History[BrainStockRanking2Day](self.two_day_symbol, 100, Resolution.Daily)
three_day_history_bars = self.History[BrainStockRanking3Day](self.three_day_symbol, 100, Resolution.Daily)
five_day_history_bars = self.History[BrainStockRanking5Day](self.five_day_symbol, 100, Resolution.Daily)
ten_day_history_bars = self.History[BrainStockRanking10Day](self.ten_day_symbol, 100, Resolution.Daily)
month_history_bars = self.History[BrainStockRanking21Day](self.month_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain ML Stock Ranking data, call the **AddUniverse** method with the **BrainStockRankingUniverse** class and a selection function.

```
def Initialize(self) -> None:
    self.AddUniverse(BrainStockRankingUniverse, "BrainStockRankingUniverse", Resolution.Daily,
self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[BrainStockRankingUniverse]) -> List[Symbol]:
    return [d.Symbol for d in alt_coarse \
                if d.Rank2Days > 0 \
                and d.Rank3Days > 0 \
                and d.Rank5Days > 0]
```

For more information about dynamic universes, see Universes .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.two_day_symbol)
self.RemoveSecurity(self.three_day_symbol)
self.RemoveSecurity(self.five_day_symbol)
self.RemoveSecurity(self.ten_day_symbol)
self.RemoveSecurity(self.month_symbol)
```

If you subscribe to Brain ML Stock Ranking data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

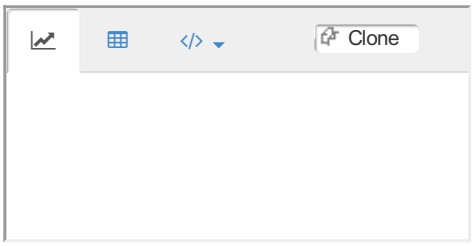
Example Applications

The Brain ML Stock Ranking dataset enables you to test strategies using the machine learning ranking provided by Brain. Examples include the following strategies:

- Constructing a portfolio of securities with each security's weight in the portfolio reflecting its Brain ML Stock Ranking

- Buying stocks with the largest Brain ML Stock Ranking
- Building a market-neutral strategy based on the top N and bottom N stocks in the Brain ML Stock Ranking

Disclaimer: The dataset is provided by the data provider for informational purposes only and do not constitute an offer to sell, a solicitation to buy, or a recommendation or endorsement for any security or strategy, nor do they constitute an offer to provide investment advisory or other services by the data provider.



Brain

Brain Sentiment Indicator

Introduction

The Brain Sentiment Indicator dataset by Brain tracks the public sentiment around US Equities. The data covers 4,500 US Equities, starts in August 2016, and is delivered on a daily frequency. This dataset is created by analyzing financial news using Natural Language Processing techniques while taking into account the similarity and repetition of news on the same topic. The sentiment score assigned to each stock ranges from -1 (most negative) to +1 (most positive). The sentiment score corresponds to the average sentiment for each piece of news. The score is updated daily and is available on two time scales: 7 days and 30 days. For more information, see Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain Sentiment Indicator dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain Sentiment Indicator dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_7day_symbol = self.AddData(BrainSentimentIndicator7Day, self.symbol).Symbol
self.dataset_30day_symbol = self.AddData(BrainSentimentIndicator30Day, self.symbol).Symbol

self.AddUniverse(BrainSentimentIndicatorUniverse, "BrainSentimentIndicatorUniverse", Resolution.Daily,
self.UniverseSelectionMethod)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2016
Asset Coverage	4,500 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Brain Sentiment Indicator dataset provides **BrainSentimentIndicatorBase** and **BrainSentimentIndicatorUniverse** objects.

BrainSentimentIndicatorBase Attributes

BrainSentimentIndicatorBase objects have the following attributes:

BrainSentimentIndicatorUniverse Attributes

BrainSentimentIndicatorUniverse objects have the following attributes:

Requesting Data

To add Brain Sentiment Indicator data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
class BrainSentimentDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2021, 7, 8)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_7day_symbol = self.AddData(BrainSentimentIndicator7Day, self.symbol).Symbol
        self.dataset_30day_symbol = self.AddData(BrainSentimentIndicator30Day, self.symbol).Symbol
```

Accessing Data

To get the current Brain Sentiment Indicator data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_7day_symbol):
        data_point = slice[self.dataset_7day_symbol]
        self.Log(f"{self.dataset_7day_symbol} sentiment at {slice.Time}: {data_point.Sentiment}")

    if slice.ContainsKey(self.dataset_30day_symbol):
        data_point = slice[self.dataset_30day_symbol]
        self.Log(f"{self.dataset_30day_symbol} sentiment at {slice.Time}: {data_point.Sentiment}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(BrainSentimentIndicator7Day).items():
        self.Log(f"{dataset_symbol} sentiment at {slice.Time}: {data_point.Sentiment}")

    for dataset_symbol, data_point in slice.Get(BrainSentimentIndicator30Day).items():
        self.Log(f"{dataset_symbol} sentiment at {slice.Time}: {data_point.Sentiment}")
```

Historical Data

To get historical Brain Sentiment Indicator data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrames
week_history_df = self.History(self.dataset_7day_symbol, 100, Resolution.Daily)
month_history_df = self.History(self.dataset_30day_symbol, 100, Resolution.Daily)
history_df = self.History([self.dataset_7day_symbol, self.dataset_30day_symbol], 100, Resolution.Daily)

# Dataset objects
week_history_bars = self.History[BrainSentimentIndicator7Day](self.dataset_7day_symbol, 100,
Resolution.Daily)
month_history_bars = self.History[BrainSentimentIndicator30Day](self.dataset_30day_symbol, 100,
Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain Sentiment Indicator data, call the **AddUniverse** method with the **BrainSentimentIndicatorUniverse** class and a selection function.

```
PY
def Initialize(self) -> None:
    self.AddUniverse(BrainSentimentIndicatorUniverse, "BrainSentimentIndicatorUniverse", Resolution.Daily,
self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[BrainSentimentIndicatorUniverse]) -> List[Symbol]:
    return [d.Symbol for d in alt_coarse \
                if d.TotalArticleMentions7Days > 0 \
                and d.Sentiment7Days]
```

The Brain Sentiment Indicator universe runs at 7 AM Eastern Time (ET) in live trading. For more information about dynamic universes, see Universes .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
PY
self.RemoveSecurity(self.dataset_7day_symbol)
self.RemoveSecurity(self.dataset_30day_symbol)
```

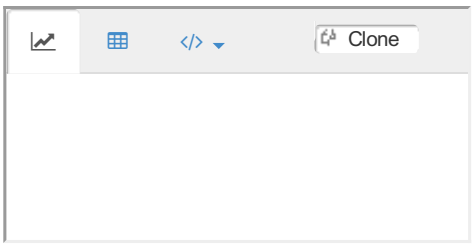
If you subscribe to Brain Sentiment Indicator data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Brain Sentiment Indicator dataset enables you to incorporate sentiment from financial news sources into your strategies. Examples include the following strategies:

- Buying when the public sentiment for a security is increasing
- Short selling when the public sentiment for a security is decreasing
- Scaling the position sizing of securities based on how many times they are mentioned in financial news articles

Disclaimer: The dataset is provided by the data provider for informational purposes only and does not constitute an offer to sell, a solicitation to buy, or a recommendation or endorsement for any security or strategy, nor do they constitute an offer to provide investment advisory or other services by the data provider.



Datasets

CBOE

The Chicago Board Options Exchange (CBOE) is the largest U.S. options exchange with annual trading volume that hovered around 1.27 billion contracts at the end of 2014. CBOE offers Options on over 2,200 companies, 22 Equity indices, and 140 exchange-traded funds (ETFs).

VIX Daily Price

CBOE

VIX Daily Price

Introduction

The VIX Daily Price dataset by CBOE covers 14 US volatility indices. The data starts in January 1990 and is delivered on a daily frequency. The dataset is cached daily from the CBOE website. The volatility index measures the stock market's expectation of volatility on the market index (e.g.: S&P500) using implied volatility from its Options for a fixed time horizon.

For more information about the VIX Daily Price dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Chicago Board Options Exchange (CBOE) is the largest U.S. options exchange with annual trading volume that hovered around 1.27 billion contracts at the end of 2014. CBOE offers Options on over 2,200 companies, 22 Equity indices, and 140 exchange-traded funds (ETFs).

Getting Started

The following snippet demonstrates how to request data from the VIX Daily Price dataset:

```
PY
from QuantConnect.DataSource import *
self.dataset_symbol = self.AddData(CBOE, "VIX", Resolution.Daily).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1990
Asset Coverage	14 US Volatility Indices
Data Density	Regular
Resolution	Daily
Timezone	New York

Supported Indices

The following table shows the volatility indices in the VIX Daily Price dataset:

Ticker	Index	Expiry	Start Date	Data Points
VIX	S&P500	30 Days	Jan 1990	OHLC
VIX9D	S&P500	9 Days	Apr 2011	OHLC
VIX3M	S&P500	3 Months	Sep 2009	OHLC
VIX6M	S&P500	6 Months	Jan 2008	OHLC
VIX1Y	S&P500	1 Year	Jan 2007	OHLC
VXO	S&P100	30 Days	Feb 1993	OHLC
VXN	Nasdaq 100	30 Days	Sep 2009	OHLC
RVX	Russell 2000	30 Days	Sep 2009	OHLC
VVIX	VIX	30 Days	Mar 2006	Close
TYVIX	10-year US Treasury Note	30 Days	Jan 2003	OHLC
VXTLT	20-year US Treasury Bond	30 Days	Jan 2004	Close
VXEEM	MSCI Emerging Markets	30 Days	Mar 2011	OHLC
OVX	United States Oil Fund (USO)	30 Days	Sep 2009	Close
GVZ	SPDR Gold Shares ETF (GLD)	30 Days	Sep 2009	Close

Data Point Attributes

The VIX Daily Price dataset provides **CBOE** objects, which have the following attributes:

Requesting Data

To add VIX Daily Price data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class CboeDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2003, 1, 1)
        self.SetEndDate(2019, 10, 11)
        self.SetCash(100000)

        self.dataset_symbol = self.AddData(CBOE, "VIX", Resolution.Daily).Symbol
```

Accessing Data

To get the current VIX Daily Price data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} close at {slice.Time}: {data_point.Close}")
```

Historical Data

To get historical VIX Daily Price data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[CBOE](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to VIX Daily Price data, call the **RemoveSecurity** method.

```
PY
self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The VIX Daily Price enables you to incorporate popular US volatility indicies in your strategies. Examples include the following strategies:

- Understanding the stock market's level of expected forward-looking volatility, also known as the "fear index". When the VIX starts moving higher, it is telling you that traders are getting nervous. When the VIX starts moving lower, it is telling you that traders are gaining confidence.
- Determining forward-looking volatility by comparing the VIX against volatility indices with other volatility. By comparing the value of the VIX to the value of the VIX3M, you can identify periods when trader sentiment has turned extremely bearish and when it has normalized.

Data Point Attributes

The Crypto Market Cap dataset provides **CoinGecko** objects, which have the following attributes:

Requesting Data

To add CoinGecko Crypto Market Cap data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
from Algorithm import *

class CoinGeckoMarketCapDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddCrypto("BTCUSD", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(CoinGecko, "BTC").Symbol
```

Accessing Data

To get the current Crypto Market Cap data, index the current **Slice** with the dataset **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} market cap::volume at {slice.Time}: {data_point.MarketCap}::
{data_point.Volume}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(CoinGecko).items():
        self.Log(f"{dataset_symbol} market cap::volume at {slice.Time}: {data_point.MarketCap}::
{data_point.Volume}")
```

Historical Data

To get historical CoinGecko Crypto Market Cap data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[CoinGecko](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Cryptos based on CoinGecko Crypto Market Cap data, call the **AddUniverse** method with the **CoinGeckoUniverse** class and a selection function. Note that the filtered output is a list of names of the

coins. If corresponding tradable crypto pairs are preferred, call **CreateSymbol(market, quoteCurrency)** method for each output item.

```
PY
def Initialize(self) -> None:
    self.AddUniverse(CoinGeckoUniverse, "CoinGeckoUniverse", Resolution.Daily, self.UniverseSelection)

def UniverseSelection(self, data: List[CoinGeckoUniverse]) -> List[Symbol]:
    for datum in data:
