        self.Debug(f'{datum.Coin},{datum.MarketCap},{datum.Price}')

    # define our selection criteria
    selected = sorted(data, key=lambda x: x.MarketCap, reverse=True)[:3]

    # Use the CreateSymbol method to generate the Symbol object for
    # the desired market (Coinbase) and quote currency (e.g. USD)
    return [x.CreateSymbol(Market.GDAX, "USD") for x in selected]
```

For more information about dynamic universes, see Universes .

Remove Subscriptions

To remove your subscription to CoinGecko Crypto Market Cap data, call the **RemoveSecurity** method.

```
PY
self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The CoinGecko Crypto Market Cap dataset provide information on the size of the crypto coin and can be used to compare the size of one coin to another. Examples include the following strategies:

- Construct a major crypto index fund.
- Invest on the cryptos with the fastest growth in market size.
- Red flag stop when there might be a crypto bank run.

Datasets

CryptoSlam!

CryptoSlam! is an NFT industry data aggregator backed by Mark Cuban. Features project analytics, NFT values, rarity, scarcity, most popular collections, activity history & more.

NFT Sales

CryptoSlam!

NFT Sales

Introduction

The NFT Sales dataset by CryptoSlam! provides Non-Fungible Tokens (NFT) sales volume data in various blockchain marketplaces. This dataset covers 11 blockchains that have their own native Cryptocurrencies. The data starts in June 2017 and is delivered on a daily frequency. This dataset fetches the number of transactions, unique buyers, unique sellers, and the dollar volume of NFT transactions on all secondary marketplaces tracked by CryptoSlam, which includes owner-to-owner sales only (not initial sales from the product directly to the owners).

For more information about the NFT Sales dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CryptoSlam! is an NFT industry data aggregator backed by Mark Cuban. Features project analytics, NFT values, rarity, scarcity, most popular collections, activity history & more.

Getting Started

The following snippet demonstrates how to request data from the NFT Sales dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddCrypto("ETHUSD", Resolution.Daily, Market.Bitfinex).Symbol
self.dataset_symbol = self.AddData(CryptoSlamNFTSales, "ETH").Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	June 2017
Asset Coverage	11 blockchains
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Supported Blockchains and Symbols

The following table shows the blockchains tracked in the NFT Sales dataset:

Symbol	Blockchain Represented	Start Date (yyyy-mm-dd)
AVAX	Avalanche	2021-09-01
CRO	Cronos	2021-12-18
ETH	Ethereum	2017-06-23
FLOW	Flow	2020-07-28
FTM	Fantom	2021-09-15
MATIC	Polygon	2021-03-01
SOL	Solana	2021-08-05
THETA	Theta	2021-06-24
WAVE	Waves	2021-06-03
WAX	Wax	2020-03-16
XTZ	Tezos	2021-03-01

Data Point Attributes

The NFT Sales dataset provides **CryptoSlamNFTSales** objects, which have the following attributes:

Requesting Data

To add NFT Sales data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
class CryptoSlamNFTSalesAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddCrypto("ETHUSD", Resolution.Daily, Market.Bitfinex).Symbol
        self.dataset_symbol = self.AddData(CryptoSlamNFTSales, "ETH").Symbol
```

Accessing Data

To get the current NFT Sales data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} unique buyers at {slice.Time}: {data_point.UniqueBuyers}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(CryptoSlamNFTSales).items():
        self.Log(f"{dataset_symbol} unique buyers at {slice.Time}: {data_point.UniqueBuyers}")
```

Historical Data

To get historical NFT Sales data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[CryptoSlamNFTSales](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
PY
self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The NFT Sales dataset enables you to incorporate NFT sales information into your strategies. Examples include the following strategies:

- Studying the correlation between the supply-demand trend of NFTs and the price changes of the underlying Cryptocurrencies.
- Measuring the activity/popularity blockchains to provide insight on the future price movements of the underlying Cryptocurrencies.

Energy Information Administration

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation"s financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

US Energy Information Administration (EIA)

Energy Information Administration

US Energy Information Administration (EIA)

Introduction

The US Energy Information Administration (EIA) datasets by the Department of the Treasury tracks national and international oil production and consumption. The data covers 190 datasets, starts in January 1991, and is delivered on a daily frequency. This dataset is created by QuantConnect processing and caching the EIA archives.

For more information about the US Energy Information Administration (EIA) dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

Getting Started

The following snippet demonstrates how to request data from the EIA dataset:

```py
from QuantConnect.DataSource import *

self.dataset_symbol = self.AddData(USEnergy,
USEnergy.Petroleum.UnitedStates.WeeklyNetImportsOfTotalPetroleumProducts).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1991
Asset Coverage	190 Datasets
Data Density	Sparse
Resolution	Daily
Timezone	New York

Supported Datasets

The following table shows the accessor code you need to add each EIA dataset to your algorithm:

Symbol	Accessor Code	Description
UnitedStates		
PET.WGFRPUS2.W	`USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderAdjustedNetProductionOfFinishedMotorGasoline`	U.S. Refiner and Blender Adjusted Net Production of Finished Motor Gasoline in Thousand Barrels per Day (Mbbl/d)

Data Point Attributes

The EIA dataset provides **USEnergy** objects, which have the following attributes:

Requesting Data

To add EIA data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class USEnergyDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.dataset_symbol = self.AddData(USEnergy,
USEnergy.Petroleum.UnitedStates.WeeklyNetImportsOfTotalPetroleumProducts).Symbol
```

Accessing Data

To get the current EIA data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} value at {slice.Time}: {data_point.Value}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(USEnergy).items():
        self.Log(f"{dataset_symbol} value at {slice.Time}: {data_point.Value}")
```

Historical Data

To get historical EIA data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[USEnergy](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

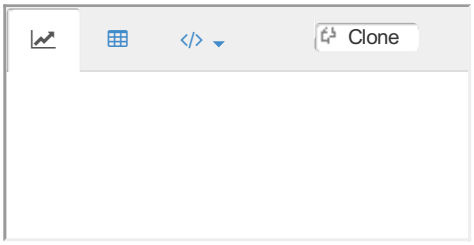
To remove your subscription to EIA data, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The EIA dataset enables you to monitor national and international oil production and consumption in you trading strategies. Examples include the following strategies:

- Trading petroleum companies when there is a change in net imports of petroleum products
- Trading country ETFs when there is a change in the country's net import of resources
- Adjusting exposure to vehicle manufacturer stocks when the supply of gasoline is higher/lower than historical levels



Datasets

ExtractAlpha

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha"s rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

ExtractAlpha

Cross Asset Model

Introduction

The Cross Asset Model by ExtractAlpha provides stock scoring values based on the trading activity in the Options market. Since the Options market has a higher proportion of institutional traders than the Equities market, the Options market is composed of investors who are more informed and information-driven on average. The data covers a dynamic universe of over 3,000 US Equities, starts in July 2005, and is delivered on a daily frequency. This dataset is created by feature engineering on the Options market put-call spread, volatility skewness, and volume.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Cross Asset Model dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Cross Asset Model dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(ExtractAlphaCrossAssetModel, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 2005
Asset Coverage	Over 3,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Cross Asset Model dataset provides **ExtractAlphaCrossAssetModel** objects, which have the following attributes:

Requesting Data

To add Cross Asset Model data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class ExtractAlphaCrossAssetModelDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(ExtractAlphaCrossAssetModel, self.symbol).Symbol
```

Accessing Data

To get the current Cross Asset Model data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} score at {slice.Time}: {data_point.Score}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(ExtractAlphaCrossAssetModel).items():
        self.Log(f"{dataset_symbol} score at {slice.Time}: {data_point.Score}")
```

Historical Data

To get historical Cross Asset Model data, call the **History** method with the dataset **Symbol** . If there is no data in the

period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[ExtractAlphaCrossAssetModel](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

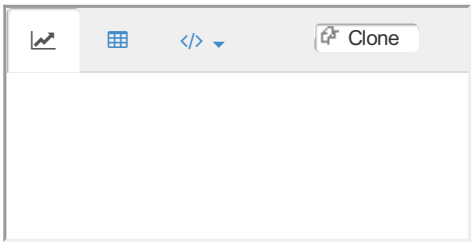
```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Cross Asset Model data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Cross Asset Model dataset by ExtractAlpha enables you to utilize Options market information to extract alpha. Examples include the following strategies:

- Predicting price and volatility changes in Equities.
- Signaling arbitrage opportunities between Options and underlying assets.
- Using it as a stock selection indicator.



ExtractAlpha

Estimize

Introduction

The Estimize dataset by ExtractAlpha estimates the financials of companies, including EPS, revenues, industry-specific KPIs, macroeconomic indicators, and more. The data covers over 2,800 US-listed Equities' EPS/Revenue, over 200 company KPIs, 27 US and 55 international macroeconomic indicator datasets, and more. The data starts in January 2011 and is delivered on a daily frequency. This dataset is crowdsourced from a community of 100,000+ contributors via the data provider's web platform.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Estimize dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Estimize dataset:

```
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.estimize_consensus_symbol = self.AddData(EstimizeConsensus, self.symbol).Symbol
self.estimize_estimate_symbol = self.AddData(EstimizeEstimate, self.symbol).Symbol
self.estimize_release_symbol = self.AddData(EstimizeRelease, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2011
Asset Coverage	2,800 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Estimize dataset provides **EstimizeConsensus** , **EstimizeEstimate** , and **EstimizeRelease** objects.

EstimizeConsensus Attributes

EstimizeConsensus objects have the following attributes:

EstimizeEstimate Attributes

EstimizeEstimate objects have the following attributes:

EstimizeRelease Attributes

EstimizeRelease objects have the following attributes:

Requesting Data

To add Estimize data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
class ExtractAlphaEstimizeDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.estimize_consensus_symbol = self.AddData(EstimizeConsensus, self.symbol).Symbol
        self.estimize_estimate_symbol = self.AddData(EstimizeEstimate, self.symbol).Symbol
        self.estimize_release_symbol = self.AddData(EstimizeRelease, self.symbol).Symbol
```

Accessing Data

To get the current Estimize data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.estimize_consensus_symbol):
        data_point = slice[self.estimize_consensus_symbol]
        self.Log(f"{self.estimize_consensus_symbol} mean at {slice.Time}: {data_point.Mean}")

    if slice.ContainsKey(self.estimize_estimate_symbol):
        data_point = slice[self.estimize_estimate_symbol]
        self.Log(f"{self.estimize_estimate_symbol} EPS at {slice.Time}: {data_point.Eps}")

    if slice.ContainsKey(self.estimize_release_symbol):
        data_point = slice[self.estimize_release_symbol]
        self.Log(f"{self.estimize_release_symbol} EPS at {slice.Time}: {data_point.Eps}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(EstimizeConsensus).items():
        self.Log(f"{dataset_symbol} mean at {slice.Time}: {data_point.Mentions}")

    for dataset_symbol, data_point in slice.Get(EstimizeEstimate).items():
        self.Log(f"{dataset_symbol} EPS at {slice.Time}: {data_point.Eps}")

    for dataset_symbol, data_point in slice.Get(EstimizeRelease).items():
        self.Log(f"{dataset_symbol} EPS at {slice.Time}: {data_point.Eps}")
```

Historical Data

To get historical Estimize data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrames
consensus_history_df = self.History(self.estimize_consensus_symbol, 100, Resolution.Daily)
estimate_history_df = self.History(self.estimize_estimate_symbol, 100, Resolution.Daily)
release_history_df = self.History(self.estimize_release_symbol, 100, Resolution.Daily)
history_df = self.History([
    self.estimize_consensus_symbol,
    self.estimize_estimate_symbol,
    self.estimize_release_symbol], 100, Resolution.Daily)

# Dataset objects
consensus_history_bars = self.History[EstimizeConsensus](self.estimize_consensus_symbol, 100,
Resolution.Daily)
estimate_history_bars = self.History[EstimizeEstimate](self.estimize_estimate_symbol, 100,
Resolution.Daily)
release_history_bars = self.History[EstimizeRelease](self.estimize_release_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

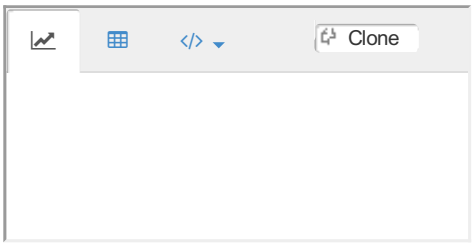
```
self.RemoveSecurity(self.estimize_consensus_symbol)
self.RemoveSecurity(self.estimize_estimate_symbol)
self.RemoveSecurity(self.estimize_release_symbol)
```

If you subscribe to Estimize data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Estimize dataset enables you to estimate the financial data of a company more accurately for alpha. Examples include the following use cases:

- Fundamental estimates for ML regression/classification models
- Arbitrage/Sentiment trading on market “surprise” from ordinary expectations based on the better expectation by the dataset
- Using industry-specific KPIs to predict the returns of individual sectors



ExtractAlpha

Tactical

Introduction

The Tactical dataset by ExtractAlpha is a stock scoring algorithm that captures the technical dynamics of individual US Equities over one to ten trading day horizons. It can assist a longer-horizon investor in timing their entry or exit points or be used in combination with existing systematic or qualitative strategies with similar holding periods.

The data covers a dynamic universe of around 4,700 US Equities per day on average, starts in January 2000, and is delivered on a daily frequency. The Tactical dataset expands upon simple reversal, liquidity, and seasonality factors to identify stocks that are likely to trend or reverse.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Tactical dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Tactical dataset:

```py
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(ExtractAlphaTacticalModel, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2000
Asset Coverage	5,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Tactical dataset provides **ExtractAlphaTacticalModel** objects, which have the following attributes:

Requesting Data

To add Tactical data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class ExtractAlphaTacticalModelDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(ExtractAlphaTacticalModel, self.symbol).Symbol
```

Accessing Data

To get the current Tactical data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} score at {slice.Time}: {data_point.Score}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(ExtractAlphaTacticalModel).items():
        self.Log(f"{dataset_symbol} score at {slice.Time}: {data_point.Score}")
```

Historical Data

To get historical Tactical data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_df = self.History[ExtractAlphaTacticalModel](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

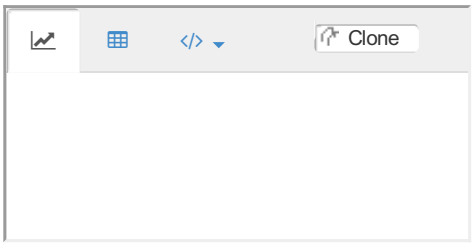
```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Tactical data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Tactical dataset enables you to gain insight into short-term stock dynamics for trading. Examples include the following strategies:

- Optimizing entry and exit times in a portfolio construction model.
- Using the raw factor values as technical indicators.
- Inputting the data into machine learning classifier models as trend/reversal labels.



ExtractAlpha

True Beats

Introduction

The True Beats dataset by ExtractAlpha provides quantitative predictions of EPS and Revenues for US Equities. The data covers a dynamic universe of around 4,000-5,000 US-listed Equities on a daily average. The data starts in January 2000 and is delivered on a daily frequency. This dataset is created by incorporating the opinions of expert analysts, historical earnings, revenue trends for the company and its peers, and metrics on company earnings management.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the True Beats dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the True Beats dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(ExtractAlphaTrueBeats, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2000
Asset Coverage	Over 5,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The True Beats dataset provides **ExtractAlphaTrueBeat** objects, which have the following attributes:

The True Beats dataset provides **ExtractAlphaTrueBeats** and **ExtractAlphaTrueBeat** objects.

ExtractAlphaTrueBeats

ExtractAlphaTrueBeats objects have the following attributes:

ExtractAlphaTrueBeat

ExtractAlphaTrueBeat objects have the following attributes:

Requesting Data

To add True Beats data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY

class ExtractAlphaTrueBeatsDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(ExtractAlphaTrueBeats, self.symbol).Symbol
```

Accessing Data

To get the current True Beats data, index the current **Slice** with the dataset **Symbol** .         self.Log(f"{dataset_symbol} True beat at {slice.Time}: {data_point.TrueBeat}")
```

Historical Data

To get historical True Beats data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[ExtractAlphaTrueBeats](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

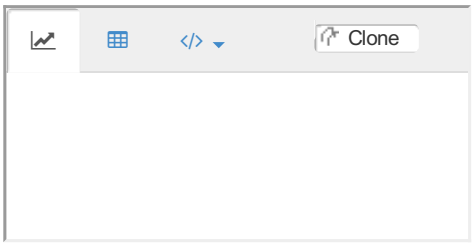
```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to True Beats data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The True Beats dataset enables you to predict EPS and revenue of US-listed Equities for trading. Examples include the following strategies:

- Finding surprise in EPS or revenue for sentiment/arbitrage trading
- Stock or sector selections based on EPS or revenue predictions
- Calculate expected return by valuation models based on EPS or revenue predictions (e.g. Black-Litterman)



Datasets

FRED

The Research Division of the Federal Reserve bank of St. Louis, MO expands the frontier of economic knowledge by producing high-quality original research in the areas of macroeconomics, money and banking, and applied microeconomics. They contribute to monetary policy discussions by advising the Bank president on a range of topics, especially in preparation for Federal Open Market Committee (FOMC) meetings. The Research Division is in the top 1% of all economics research departments worldwide.

US Federal Reserve (FRED)

FRED

US Federal Reserve (FRED)

Introduction

The Federal Reserve Economic Data (FRED) by the Research Division of the Federal Reserve bank of St. Louis, MO provides various time series relating to macro-economic data. The data covers 560 datasets, starts in January 1999, and is delivered on a daily frequency. The data is created by aggregating daily updates from more than 85 public and proprietary sources.

For more information about the US Federal Reserve (FRED) dataset, including CLI commands and pricing, see the dataset listing .

Data Point Attributes

The FRED dataset provides **Fred** objects, which have the following attributes:

Requesting Data

To add FRED data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
class FredAlternativeDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2003, 1, 1)
        self.SetEndDate(2019, 10, 11)
        self.SetCash(100000)

        self.dataset_symbol = self.AddData(Fred,
Fred.OECDRecessionIndicators.UnitedStatesFromPeakThroughTheTrough, Resolution.Daily).Symbol
```

Accessing Data

To get the current FRED data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} value at {slice.Time}: {data_point.Value}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(Fred).items():
        self.Log(f"{dataset_symbol} value at {slice.Time}: {data_point.Value}")
```

Historical Data

To get historical FRED data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[Fred](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to FRED data, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The FRED dataset enables you to accurately design strategies utilizing macroeconomic indicators. Examples include the following strategies:

- Trading on macroeconomic factors
- Macroeconomic risk modeling

Datasets

Kavout

Kavout was created by ex-Googlers and the founding team used to work at Google, Microsoft, Baidu, and financial firms with a proven track record of building many mission-critical machine learning systems where billions of data points were processed in real-time to predict the best outcome for core search ranking, ads monetization, recommendations, and trading platforms.

Their mission is to build machine investing solutions to find alpha with adaptive learning algorithms and to create an edge by assimilating vast quantities of complex data through the latest AI and Machine Learning methods to generate signals to uncover hidden, dynamic, and nonlinear patterns in the financial markets.

Composite Factor Bundle

Kavout

Composite Factor Bundle

Introduction

The Composite Factor Bundle dataset by Kavout provides ensemble scores for popular market factors. Kavout signals are machine-learning enhanced scores that capture the returns of systematic factors such as quality, value, momentum, growth, and low volatility. There are many different anomalies discovered by researchers and practitioners across these factor categories and there is no good common definition of each style across the literature. Kavout creates an ensemble score for each style that gauges the different factors considered in the literature and industry practice.

In this data set, you will find Kavout's proprietary signals for quality, value, momentum, growth, and low volatility, which have been adopted by some of the multi-billion dollar quant funds in New York and London. Each signal is generated by an ensemble model consisting of inputs from hundreds of anomalies. The data is generated on a daily basis and covers all the stocks traded in US major markets such as NYSE and Nasdaq since 2003. You could leverage this abundant set of signals to construct and backtest your strategies.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Composite Factor Bundle dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Kavout was created by ex-Googlers and the founding team used to work at Google, Microsoft, Baidu, and financial firms with a proven track record of building many mission-critical machine learning systems where billions of data points were processed in real-time to predict the best outcome for core search ranking, ads monetization, recommendations, and trading platforms.

Their mission is to build machine investing solutions to find alpha with adaptive learning algorithms and to create an edge by assimilating vast quantities of complex data through the latest AI and Machine Learning methods to generate signals to uncover hidden, dynamic, and nonlinear patterns in the financial markets.

Getting Started

The following snippet demonstrates how to request data from the Composite Factor Bundle dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(KavoutCompositeFactorBundle, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2003
Asset Coverage	8,000 US Equities
Data Density	Regular
Resolution	Daily
Timezone	UTC

Data Point Attributes

Template content example

The Composite Factor Bundle dataset provides **KavoutCompositeFactorBundle** objects, which have the following attributes:

Requesting Data

To add Composite Factor Bundle data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class KavoutCompositeFactorBundleAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(KavoutCompositeFactorBundle, self.symbol).Symbol
```

Accessing Data

To get the current Composite Factor Bundle data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} momentum at {slice.Time}: {data_point.Momentum}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(KavoutCompositeFactorBundle).items():
        self.Log(f"{dataset_symbol} momentum at {slice.Time}: {data_point.Momentum}")
```

Historical Data

To get historical Composite Factor Bundle data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[KavoutCompositeFactorBundle](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

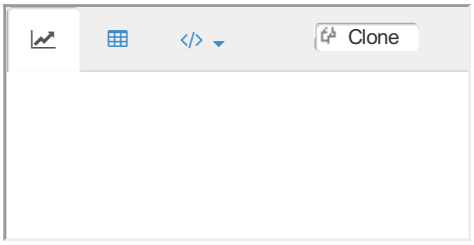
```
PY
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Composite Factor Bundle data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Composite Factor Bundle dataset enables you to access the performance of 5 different factors in order to engineer strategies. Examples include the following strategies:

- Performing return-risk optimization based on performance and volatility scoring.
- Weighing stocks based on regression analysis in factor-vector space.



Datasets

Nasdaq

" Nasdaq " was initially an acronym for the National Association of Securities Dealers Automated Quotations. It was founded in 1971 by the National Association of Securities Dealers (NASD), now known as the Financial Industry Regulatory Authority (FINRA), with the goal to provide financial services and operate stock exchanges.

On Dec. 4th, 2018, Nasdaq announced it had acquired Quandl, Inc. , a leading provider of alternative and core financial data. Quandl was founded by Tammer Kamel in 2012, with goal of making it easy for anyone to find and use high-quality data effectively in their professional decision-making. In 2021, Quandl was replaced by Nasdaq Data Link .

Data Link

Nasdaq

Data Link

Introduction

The Data Link dataset by Nasdaq, previously known as Quandl, is a collection of alternative data sets. It has indexed millions of time-series datasets from over 400 sources, which start in different years. This dataset is delivered on several frequencies, but the free data sets have often a daily frequency.

For more information about the Data Link dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

" Nasdaq " was initially an acronym for the National Association of Securities Dealers Automated Quotations. It was founded in 1971 by the National Association of Securities Dealers (NASD), now known as the Financial Industry Regulatory Authority (FINRA), with the goal to provide financial services and operate stock exchanges.

On Dec. 4th, 2018, Nasdaq announced it had acquired Quandl, Inc. , a leading provider of alternative and core financial data. Quandl was founded by Tammer Kamel in 2012, with goal of making it easy for anyone to find and use high-quality data effectively in their professional decision-making. In 2021, Quandl was replaced by Nasdaq Data Link .

Getting Started

The following snippet demonstrates how to request data from the Data Link dataset:

```
PY
from QuantConnect.DataSource import *

# For premium datasets, provide your API Key
# NasdaqDataLink.SetAuthCode(self.GetParameter("nasdaq-data-link-api-key"))

self.pe_ratio_symbol = self.AddData(NasdaqDataLink, "MULTPL/SP500_PE_RATIO_MONTH",
Resolution.Daily).Symbol
# This dataset has one data column ("Value")

self.position_change_symbol = self.AddData(NasdaqCustomColumns, "CFTC/066393_FO_L_CHG",
Resolution.Daily).Symbol
# This dataset has multiple data columns. Create a subclass to set the default value column.

class NasdaqCustomColumns(NasdaqDataLink):
    def __init__(self) -> None:
        # Select the column "open interest - change".
        self.ValueColumnName = "open interest - change"
```

Our Nasdaq Data Link integration supports any dataset from Nasdaq that has a URL starting with **data.nasdaq.com/data/** . To import a dataset from Data Link, you need to get the dataset code. Follow these steps to get the dataset code:

1. Open the Data Link catalog .
2. *(Optional)* Use the filters on the left side bar to narrow down the catalog results.
3. Click one of the data products.

4. On the data product page, click one of the table names.
5. In the top-right corner of the dataset page, copy the Nasdaq Data Link Code.

Data Summary

The data summary depends on the specific Data Link dataset you use. Follow these steps to view the data summary of a dataset:

1. Open the Data Link catalog .
2. Click one of the data products.
3. On the data product page, click one of the table names.
4. View the data frequency and description in the left sidebar.
5. Above the chart, click **Table** to view the start date, end date, and data point attributes.

Backward Compatibility

QuantConnect/LEAN has supported Quandl since 2015. On January, 12, 2022, we moved the implementation from the LEAN GitHub repository to the Lean.DataSource.NasdaqDataLink GitHub repository . Through this transition, we maintained backward compatibility. All of the preceding code snippets work if you replace **NasdaqDataLink** with **Quandl** .

Requesting Data

To add Data Link data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm. If there is more than one value column in the Data Link dataset, to set the **Value** property of the data objects, create a sublcass of the **NasdaqDataLink** class and set its **ValueColumnName** property to the column name.

```
PY
class NasdaqDataLinkDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2022, 1, 1)
        self.SetEndDate(2022, 7, 1)
        self.SetCash(100000)

        # For premium datasets, provide your API Key
        # NasdaqDataLink.SetAuthCode(self.GetParameter("nasdaq-data-link-api-key"))

        self.pe_ratio_symbol = self.AddData(NasdaqDataLink, "MULTPL/SP500_PE_RATIO_MONTH",
Resolution.Daily).Symbol
        # This dataset has one data column ("Value")
        # Source : https://data.nasdaq.com/data/MULTPL/SP500_PE_RATIO_MONTH-sp-500-pe-ratio-by-month

        self.position_change_symbol = self.AddData(NasdaqCustomColumns, "CFTC/066393_FO_L_CHG",
Resolution.Daily).Symbol
        # This dataset has multiple data columns
        # Source: https://data.nasdaq.com/data/CFTC/066393_FO_L_CHG-commitment-of-traders-propane-argus-
far-east-mini-ifed-futures-and-options-change-in-positions-legacy-format-066393

class NasdaqCustomColumns(NasdaqDataLink):
    def __init__(self) -> None:
        # Select the column "open interest - change".
        self.ValueColumnName = "open interest - change"
```

Accessing Data

To get the current Data Link data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid

issues, check if the **Slice** contains the data you want before you index it.

To get the default value of the dataset, use the **Value** property. To get the value of a specific column in the dataset, call the **GetStorageDictionary** method and index the result with the column name.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.pe_ratio_symbol):
        value = slice[self.pe_ratio_symbol].Value
        self.Log(f"{self.pe_ratio_symbol} PE ratio at {slice.Time}: {value}")

    if slice.ContainsKey(self.position_change_symbol):
        data_point = slice[self.position_change_symbol]
        open_interest_change = data_point.Value
        storage_dictionary = data_point.GetStorageDictionary()
        longs_change = storage_dictionary["noncommercial longs - change"]
        self.Log(f"{self.position_change_symbol} open interest change at {slice.Time}:
{open_interest_change}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(NasdaqDataLink).items():
        self.Log(f"{dataset_symbol} PE ratio at {slice.Time}: {data_point.Value}")

    for dataset_symbol, data_point in slice.Get(NasdaqCustomColumns).items():
        self.Log(f"{dataset_symbol} value at {slice.Time}: {data_point.Value}")
```

Historical Data

The process to get historical Data Link data depends on your environment.

In Algorithms

To get historical Data Link data in an algorithm, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrames
pe_ratio_history_df = self.History(self.pe_ratio_symbol, 100, Resolution.Daily)
position_change_history_df = self.History(self.position_change_symbol, 100, Resolution.Daily)

# Dataset objects
pe_ratio_history_df = self.History[NasdaqDataLink](self.pe_ratio_symbol, 100, Resolution.Daily)
position_change_history_df = self.History[NasdaqCustomColumns](self.position_change_symbol, 100,
Resolution.Daily)
```

For more information about historical data, see History Requests .

In Research Notebooks

To get historical Data Link data in the Research Environment, call the **Download** method with the data URL.

```
PY
from io import StringIO
data = qb.Download("data.nasdaq.com/api/v3/datasets/MULTPL/SP500_PE_RATIO_MONTH.csv?")
df = pd.read_csv(StringIO(data), index_col=0)
```

To receive a notification when you can use the **History** method in the Research Environment to get data from Data Link, subscribe to Lean.DataSource.NasdaqDataLink GitHub Issue #10 .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
PY
self.RemoveSecurity(self.pe_ratio_symbol)
self.RemoveSecurity(self.position_change_symbol)
```

Example Applications

The Nasdaq Data Link sources allow you to explore different kinds of data in their database to develop trading strategies. Examples include the following strategies:

- Using alternative data to regress market regime/asset price.
- Backtesting exotic derivatives or private Equity investments.

Quiver Quantitative

CNBC Trading

Introduction

The CNBC Trading dataset by Quiver Quantitative tracks the recommendations made by media personalities on CNBC and their historical performance. The data covers over 1,500 US Equities, starts in December 2020, and is delivered on a daily frequency. This dataset covers recommendations made on Mad Money, Halftime Report, and Fast Money.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the CNBC Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the CNBC Trading dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(QuiverCNBCs, self.symbol).Symbol

self.AddUniverse(QuiverCNBCsUniverse, "QuiverCNBCsUniverse", Resolution.Daily,
self.UniverseSelectionFilter)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	December 25, 2020
Asset Coverage	1,515 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Quiver Quantitative CNBC Trading dataset provides **QuiverCNBCs** , **QuiverCNBC** , and **QuiverCNBCsUniverse** objects.

QuiverCNBCs

QuiverCNBCs objects have the following attributes:

QuiverCNBC

QuiverCNBC objects have the following attributes:

QuiverCNBCsUniverse

QuiverCNBCsUniverse objects have the following attributes:

Requesting Data

To add CNBC Trading data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class QuiverCNBCDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(QuiverCNBCs, self.symbol).Symbol
```

Accessing Data

To get the current CNBC Trading data, index the current **Slice** with the dataset **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.Log(f"{self.dataset_symbol} direction at {slice.Time}: {data_point.Direction}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_points in slice.Get(QuiverCNBCs).items():
        for data_point in data_points:
            self.Log(f"{dataset_symbol} direction at {slice.Time}: {data_point.Direction}")
```

Historical Data

To get historical CNBC Trading data, call the **History** method with the dataset **Symbol** . If there is no data in the

period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[QuiverCNBCs](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on CNBC Trading data, call the **AddUniverse** method with the **QuiverCNBCsUniverse** class and a selection function.

```
self.AddUniverse(QuiverCNBCsUniverse, "QuiverCNBCsUniverse", Resolution.Daily, self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[QuiverCNBCsUniverse]) -> List[Symbol]:
    cnbc_data_by_symbol = {}

    for datum in alt_coarse:
        symbol = datum.Symbol

        if symbol not in cnbc_data_by_symbol:
            cnbc_data_by_symbol[symbol] = []
        cnbc_data_by_symbol[symbol].append(datum)

    # define our selection criteria
    return [symbol for symbol, d in cnbc_data_by_symbol.items()
            if len([x for x in d if x.Direction == OrderDirection.Buy]) >= 3]
```

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to CNBC Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative CNBC Trading dataset enables you to create strategies using the latest recommendations made by media personalities on CNBC. Examples include the following strategies:

- Taking short positions in securities that were mentioned by Jim Cramer (CNBC commentator) in the last week
- Trading securities that were most/least discussed across CNBC programs over the last year

Quiver Quantitative

Corporate Lobbying

Introduction

The Corporate Lobbying dataset by Quiver Quantitative tracks the lobbying activity of US Equities. The Lobbying Disclosure Act of 1995 requires lobbyists in the United States to disclose information about their activities, such as their clients, which issues they are lobbying on, and how much they are being paid. Quiver Quantiative scrapes this data and maps it to stock tickers to track which companies are spending money for legislative influence.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Corporate Lobbying dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the Corporate Lobbying dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(QuiverLobbyings, self.symbol).Symbol

self.AddUniverse(QuiverLobbyingUniverse, "QuiverLobbyingUniverse", Resolution.Daily,
self.UniverseSelectionFilter)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 4, 1999
Asset Coverage	1,418 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Quiver Quantitative Corporate Lobbying dataset provides **QuiverLobbyings** , **QuiverLobbying** , and **QuiverLobbyingUniverse** objects.

QuiverLobbyings

QuiverLobbyings objects have the following attributes:

QuiverLobbying

QuiverLobbying objects have the following attributes:

QuiverLobbyingUniverse

QuiverLobbyingUniverse objects have the following attributes:

Requesting Data

To add Corporate Lobbying data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
class QuiverLobbyingDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(QuiverLobbyings, self.symbol).Symbol
```

PY

Accessing Data

To get the current Corporate Lobbying data, index the current Slice with the dataset **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.Log(f"{self.dataset_symbol} amount at {slice.Time}: {data_point.Amount}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_points in slice.Get(QuiverLobbyings).items():
        for data_point in data_points:
            self.Log(f"{dataset_symbol} amount at {slice.Time}: {data_point.Amount}")
```

Historical Data

To get historical Corporate Lobbying data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[QuiverLobbyings](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Corporate Lobbying data, call the **AddUniverse** method with the **QuiverLobbyingUniverse** class and a selection function.

```
self.AddUniverse(QuiverLobbyingUniverse, "QuiverLobbyingUniverse", Resolution.Daily,
self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[QuiverLobbyingUniverse]) -> List[Symbol]:
    lobby_data_by_symbol = {}

    for datum in alt_coarse:
        symbol = datum.Symbol

        if symbol not in lobby_data_by_symbol:
            lobby_data_by_symbol[symbol] = []
        lobby_data_by_symbol[symbol].append(datum)

    return [symbol for symbol, d in lobby_data_by_symbol.items()
            if sum([x.Amount for x in d]) >= 100000]
```

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Corporate Lobbying data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Corporate Lobbying dataset enables you to create strategies using the latest information on lobbying activity. Examples include the following strategies:

- Trading securities that have spent the most on lobbying over the last quarter
- Trading securities that have had the biggest change in lobbying spend for privacy legislation over the last year

Quiver Quantitative

Insider Trading

Introduction

Corporate insiders are required to disclose purchases or sales of their own stock within two business days of when they occur. Using these disclosures, we collect data on insider trading activity, which can give hints on whether executives are bullish or bearish on their own companies. Here is a blog that we did on this dataset: https://www.quiverquant.com/blog/081121

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Insider Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the Insider Trading dataset:

```
PY
from QuantConnect.DataSource import *

aapl = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.quiver_insider_trading_symbol = self.AddData(QuiverInsiderTradings, aapl).Symbol
self.AddUniverse(QuiverInsiderTradingUniverse, "QuiverInsiderTradingUniverse", Resolution.Daily,
self.UniverseSelection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	25 April 2014
Asset Coverage	4994 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The Insider Trading dataset provides **QuiverInsiderTrading** objects encapsulated in a **QuiverInsiderTradings** object, and **QuiverInsiderTradingUniverse** object.

QuiverInsiderTradings

QuiverInsiderTradings objects have the following attributes:

QuiverInsiderTrading

QuiverInsiderTrading objects have the following attributes:

QuiverInsiderTradingUniverse

QuiverInsiderTradingUniverse objects have the following attributes:

Requesting Data

To add Insider Trading data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class QuiverInsiderTradingDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(QuiverInsiderTradings, self.symbol).Symbol
```

Accessing Data

To get the current Insider Trading data, index the current **Slice** with the dataset **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.Log(f"{self.dataset_symbol} shares at {slice.Time}: {data_point.Shares}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_points in slice.Get(QuiverInsiderTradings).items():
        for data_point in data_points:
            self.Log(f"{dataset_symbol} shares at {slice.Time}: {data_point.Shares}")
```

Historical Data

To get historical Insider Trading data, call the **History** method with the dataset **Symbol** . If there is no data in the

period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
self.History[QuiverInsiderTradings](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Insider Trading data, call the **AddUniverse** method with the **QuiverInsiderTradingUniverse** class and a selection function.

```
self.AddUniverse(QuiverInsiderTradingUniverse, "QuiverInsiderTradingUniverse", Resolution.Daily,
self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[QuiverInsiderTradingUniverse]) -> List[Symbol]:
    insider_trading_data_by_symbol = {}

    for datum in alt_coarse:
        symbol = datum.Symbol

        if symbol not in insider_trading_data_by_symbol:
            insider_trading_data_by_symbol[symbol] = []
        insider_trading_data_by_symbol[symbol].append(datum)

    return [symbol for symbol, d in insider_trading_data_by_symbol.items()
            if len([x for x in d if x.Direction == OrderDirection.Buy]) >= 3]
```

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Insider Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative Insider Trading dataset enables researchers to create strategies using the latest information on insider trading activity. Examples include:

- Taking a short position in securities that have had the most insider selling over the last 5 days
- Buying any security that has had over $100,000 worth of shares purchased by insiders in the last month

Quiver Quantitative

Twitter Followers

Introduction

The Twitter Followers dataset by Quiver Quantitative tracks the number of followers on the official Twitter pages of US-listed companies. The data covers 2,000 equities, starts in May 2020, and is delivered on a daily frequency. This dataset is created by scraping the number of Twitter followers from the official Twitter page of the security.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Twitter Followers dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the Twitter Followers dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(QuiverQuantTwitterFollowers, self.symbol).Symbol

self.AddUniverse(QuiverQuantTwitterFollowersUniverse, "QuiverQuantTwitterFollowersUniverse",
Resolution.Daily, self.UniverseSelectionMethod)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2020
Asset Coverage	2,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	Chicago

Data Point Attributes

The Twitter Followers dataset provides **QuiverQuantTwitterFollowers** and **QuiverQuantTwitterFollowersUniverse** objects.

QuiverQuantTwitterFollowers Attributes

QuiverQuantTwitterFollowers objects have the following attributes:

QuiverQuantTwitterFollowersUniverse Attributes

QuiverQuantTwitterFollowersUniverse objects have the following attributes:

Requesting Data

To add Twitter Followers data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class QuiverQuantTwitterFollowersDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(QuiverQuantTwitterFollowers, self.symbol).Symbol
```

Accessing Data

To get the current Twitter Followers data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} followers at {slice.Time}: {data_point.Followers}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(QuiverQuantTwitterFollowers).items():
        self.Log(f"{dataset_symbol} followers at {slice.Time}: {data_point.Followers}")
```

Historical Data

To get historical Twitter Followers data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[QuiverQuantTwitterFollowers](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Twitter Followers data, call the **AddUniverse** method with the **QuiverQuantTwitterFollowersUniverse** class and a selection function.

```
def Initialize(self) -> None:
    self.AddUniverse(QuiverQuantTwitterFollowersUniverse, "QuiverQuantTwitterFollowersUniverse",
Resolution.Daily, self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[QuiverQuantTwitterFollowersUniverse]) -> List[Symbol]:
    return [d.Symbol for d in alt_coarse \
                if d.Followers > 200000 \
                and d.WeekPercentChange > 0]
```

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Twitter Followers data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Twitter Followers dataset enables you to create strategies using the number of Twitter followers for companies. Examples include the following strategies:

- Trading securities that are on a upward/downward trend for number of followers
- Trading the security that has the highest/lowest increase in followers on a given day
- Trading securities with big changes in their follower count, prices, and volume

Quiver Quantitative

US Congress Trading

Introduction

The US Congress Trading dataset by Quiver Quantitative tracks US Equity trades made by members of Congress in the Senate and the House of Representatives. The data covers 1,800 US Equities, starts in January 2016, and is delivered on a daily frequency. This dataset is created by scraping SEC reports.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Congress Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the US Congress Trading dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
self.dataset_symbol = self.AddData(QuiverCongress, self.symbol).Symbol

self.AddUniverse(QuiverQuantCongressUniverse, "QuiverQuantCongresssUniverse", Resolution.Daily,
self.UniverseSelection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2016
Asset Coverage	1,800 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The US Congress Trading dataset provides **QuiverCongress** and **QuiverQuantCongressUniverse** objects.

QuiverCongress Attributes

QuiverCongress object has the following attributes:

QuiverQuantCongressUniverse Attributes

QuiverQuantCongressUniverse object has the following attributes:

Requesting Data

To add US Congress Trading data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class QuiverCongressDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Daily).Symbol
        self.dataset_symbol = self.AddData(QuiverCongress, self.symbol).Symbol
```

Accessing Data

To get the current US Congress Trading data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} transaction amount at {slice.Time}: {data_point.Amount}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(QuiverCongress).items():
        self.Log(f"{dataset_symbol} transaction amount at {slice.Time}: {data_point.Amount}")
```

Historical Data

To get historical US Congress Trading data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[QuiverCongress](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on US Congress Trading data, call the **AddUniverse** method with the **QuiverQuantCongressUniverse** class and a selection function.

```
def Initialize(self) -> None:
    self.AddUniverse(QuiverQuantCongressUniverse, "QuiverQuantCongresssUniverse", Resolution.Daily,
self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[QuiverQuantCongresssUniverse]) -> List[Symbol]:
    return [d.Symbol for d in alt_coarse \
        if d.Amount > 200000 and d.Transaction == OrderDirection.Buy]
```

For more information about dynamic universes, see Universes .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to US Congress Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The US Congress Trading dataset enables you to take immediate action on trades made by informed Members of Congress. Examples include the following strategies:

- Following the trades of specific representatives on the premise that the representatives are more informed
- Assigning a long/short-bias to securities on a daily frequency based on how Members of Congress are trading them

Quiver Quantitative

US Government Contracts

Introduction

The US Government Contracts dataset by Quiver Quantitative tracks the transactions of government contracts with publicly traded companies. The data covers over 700 US Equities, starts in October 2019, and is delivered on a daily frequency. Quiver Quantitative creates this dataset by using the API for USASpending.gov , which has the official open data source of federal spending information. The rows in this dataset only show new contracts, not payments or modifications to existing contracts. The dollar amounts are based on the total dollars obligated from each contract.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Government Contracts dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on US Government Contract data, call the **AddUniverse** method with the **QuiverGovernmentContractUniverse** class and a selection function.

```
PY

self.AddUniverse(QuiverGovernmentContractUniverse, "QuiverGovernmentContractUniverse", Resolution.Daily,
self.UniverseSelection)

def UniverseSelection(self, alt_coase: List[QuiverGovernmentContractUniverse]) -> List[Symbol]:
    gov_contract_data_by_symbol = {}

    for datum in alt_coarse:
        symbol = datum.Symbol

        if symbol not in gov_contract_data_by_symbol:
            gov_contract_data_by_symbol[symbol] = []
        gov_contract_data_by_symbol[symbol].append(datum)

    return [symbol for symbol, d in gov_contract_data_by_symbol.items()
            if len(d) >= 3 and sum([x.Amount for x in d]) > 50000]
```

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
PY

self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to US Government Contracts data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative US Government Contracts dataset enables you to create strategies using the latest information on government contracts activity. Examples include the following strategies:

- Buying securities that have received the most new government contracts awards over the last month
- Trading securities that have had the biggest change in government contracts awards over the last year

Quiver Quantitative

WallStreetBets

Introduction

The WallStreetBets dataset by Quiver Quantitative tracks daily mentions of different equities on Reddit's popular WallStreetBets forum. The data covers 6,000 Equities, starts in August 2018, and is delivered on a daily frequency. The dataset is created by scraping the daily discussion threads on r/WallStreetBets and parsing the comments for ticker mentions.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the WallStreetBets dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

        self.dataset_symbol = self.AddData(QuiverWikipedia, self.symbol).Symbol
```

Accessing Data

To get the current Wikipedia Page Views data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} weekly page views percentage change at {slice.Time}:
{data_point.WeekPercentChange}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(QuiverWikipedia).items():
        self.Log(f"{dataset_symbol} weekly page views percentage change at {slice.Time}:
{data_point.WeekPercentChange}")
```

Historical Data

To get historical Wikipedia Page Views data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[QuiverWikipedia](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Wikipedia Page Views data, call the **AddUniverse** method with the **QuiverWikipediaUniverse** class and a selection function.

```
def Initialize(self) -> None:
    self.AddUniverse(QuiverWikipediaUniverse, "QuiverWikipediaUniverse", Resolution.Daily,
self.UniverseSelection)

def UniverseSelection(self, alt_coarse: List[QuiverWikipediaUniverse]) -> List[Symbol]:
    return [d.Symbol for d in alt_coarse \
                if d.PageViews > 100 \
                and d.WeekPercentChange < 0.2]
```

For more information about dynamic universes, see Universes .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Wikipedia Page Views data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Wikipedia Page Views dataset enables you to observe patterns in the traffic of company Wikipedia pages. Examples include the following strategies:

- Capitalizing on companies that have experienced a sharp increase in Wikipedia traffic on the premise that volatility in traffic will translate to volatility in price
- Mitigating risk by avoiding companies that have a decreasing web presence on the premise that a reduction in traffic will result in a reduction in price

RegAlytics

RegAlytics was founded by Mary Kopczynski, Aaron Heisler, Alexander Appugliese, and Werner Pauliks in 2019 with the goal of significantly reducing the time and cost required to mitigate regulatory risk. RegAlytics provides access to accurate and clean regulatory data from all global regulators in all sectors that is enriched by regulatory experts for risk and compliance teams everywhere. Please come to RegAlytics directly if you would like data on other sectors or countries!

US Regulatory Alerts - Financial Sector

RegAlytics

US Regulatory Alerts - Financial Sector

Introduction

The US Regulatory Alerts dataset by RegAlytics tracks US regulatory changes within the financial services sector. The data covers 400,000 alerts, starts from January 2020, and is delivered on a daily basis. This dataset is created by sourcing information from over 5,000 regulators and using proprietary technology to gather and structure the regulatory data. Once prepared, the data is thoroughly reviewed by RegAlytics' team of regulatory experts and delivered each morning by 8AM for industry use.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Regulatory Alerts - Financial Sector dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

RegAlytics was founded by Mary Kopczynski, Aaron Heisler, Alexander Appugliese, and Werner Pauliks in 2019 with the goal of significantly reducing the time and cost required to mitigate regulatory risk. RegAlytics provides access to accurate and clean regulatory data from all global regulators in all sectors that is enriched by regulatory experts for risk and compliance teams everywhere. Please come to RegAlytics directly if you would like data on other sectors or countries!

Getting Started

The following snippet demonstrates how to request data from the US Regulatory Alerts - Financial Sector dataset:

```
PY
from QuantConnect.DataSource import *
self.dataset_symbol = self.AddData(RegalyticsRegulatoryArticles, "REG").Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2020
Coverage	400,000 Alerts
Data Density	Sparse
Resolution	Daily
Timezone	New York

Data Point Attributes

The US Regulatory Alerts dataset provides **RegalyticsRegulatoryArticle** and **RegalyticsRegulatoryArticles** objects.

RegalyticsRegulatoryArticle

RegalyticsRegulatoryArticle objects have the following attributes:

RegalyticsRegulatoryArticles

RegalyticsRegulatoryArticles objects have the following attributes:

Requesting Data

To add US Regulatory Alerts data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class RegalyticsDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        self.dataset_symbol = self.AddData(RegalyticsRegulatoryArticles, "REG").Symbol
```

Accessing Data

To get the current US Regulatory Alerts data, index the current **Slice** with the dataset **Symbol** . **Slice** objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_points = slice[self.dataset_symbol]
        for data_point in data_points:
            self.Log(f"{self.dataset_symbol} title at {slice.Time}: {data_point.Title}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
def OnData(self, slice: Slice) -> None:
    data = slice.Get(RegalyticsRegulatoryArticles)
    if data:
        for articles in data.values():
            self.Log(f"{self.Time} {articles.ToString()}")

            for article in articles:
                self.Log(f"{self.dataset_symbol} article title at {slice.Time}: {article.Title}")
```

Historical Data

To get historical US Regulatory Alerts data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars =  self.History[RegalyticsRegulatoryArticles](self.dataset_symbol, 100, Resolution.Daily)
```

Remove Subscriptions

To remove your subscription to US Regulatory Alerts data, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The US Regulator Alters dataset enables you to accurately design strategies while mitigating regulatory risk. Examples include the following strategies:

- Temporarily increasing/decreasing exposure to securities when new regulations are announced
- Parsing the content of regulatory announcements to determine market or sector impact

Datasets

Securities and Exchange Commission

The mission of the U.S. Securities and Exchange Commission is to protect investors, maintain fair, orderly, and efficient markets, and facilitate capital formation. The SEC oversees the key participants in the securities world, including securities exchanges, securities brokers and dealers, investment advisors, and mutual funds. The SEC is concerned primarily with promoting the disclosure of important market-related information, maintaining fair dealing, and protecting against fraud.

US SEC Filings

Securities and Exchange Commission

US SEC Filings

Introduction

The US SEC Filings dataset provides the quarterly financial earning reports that the United States Securities and Exchange Commission (SEC) requires from publicly traded companies in the US. The data covers 15,000 US Equities, starts in January 1998, and is delivered on a daily frequency. The data is sourced from the SEC's Electronic Data Gathering, Analysis, and Retrieval (EDGAR) system. QuantConnect downloads and formats the Quarterly Financial Reports (10-Q) and Annual Financial Report (8-K) filings of companies into a format for easy consumption by LEAN.

For more information about the US SEC Filings dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The mission of the U.S. Securities and Exchange Commission is to protect investors, maintain fair, orderly, and efficient markets, and facilitate capital formation. The SEC oversees the key participants in the securities world, including securities exchanges, securities brokers and dealers, investment advisors, and mutual funds. The SEC is concerned primarily with promoting the disclosure of important market-related information, maintaining fair dealing, and protecting against fraud.

Getting Started

The following snippet demonstrates how to request data from the US SEC Filings dataset:

```py
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Minute).Symbol
self.report_8k_symbol = self.AddData(SECReport8K, self.symbol).Symbol
self.report_10k_symbol = self.AddData(SECReport10K, self.symbol).Symbol
self.report_10q_symbol = self.AddData(SECReport10Q, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	15,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Data Point Attributes

The US SEC Filings dataset provides **SECReport8K** , **SECReport10K** , and **SECReport10Q** objects.

Report 8K Attributes

SECReport8K objects have the following attributes:

Report 10K Attributes

SECReport10K objects have the following attributes:

Report 10Q Attributes

SECReport10Q objects have the following attributes:

Requesting Data

To add US SEC Filings data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class SECReportAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2019, 8, 21)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Minute).Symbol
        self.report_8k_symbol = self.AddData(SECReport8K, self.symbol).Symbol
        self.report_10k_symbol = self.AddData(SECReport10K, self.symbol).Symbol
        self.report_10q_symbol = self.AddData(SECReport10Q, self.symbol).Symbol
```

Accessing Data

To get the current US SEC Filings data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.report_8k_symbol):
        data_point = slice[self.report_8k_symbol]
        self.Log(f"{self.report_8k_symbol} report count at {slice.Time}:
{len(data_point.Report.Documents)}")

    if slice.ContainsKey(self.report_10k_symbol):
        data_point = slice[self.report_10k_symbol]
        self.Log(f"{self.report_10k_symbol} report count at {slice.Time}:
{len(data_point.Report.Documents)}")

    if slice.ContainsKey(self.report_10q_symbol):
        data_point = slice[self.report_10q_symbol]
        self.Log(f"{self.report_10q_symbol} report count at {slice.Time}:
{len(data_point.Report.Documents)}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(SECReport8K).items():
        self.Log(f"{dataset_symbol} report count at {slice.Time}: {len(data_point.Report.Documents)}")

    for dataset_symbol, data_point in slice.Get(SECReport10K).items():
        self.Log(f"{dataset_symbol} report count at {slice.Time}: {len(data_point.Report.Documents)}")

    for dataset_symbol, data_point in slice.Get(SECReport10Q).items():
        self.Log(f"{dataset_symbol} report count at {slice.Time}: {len(data_point.Report.Documents)}")
```

Historical Data

To get historical US SEC Filings data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
# DataFrames
report_8k_history_df = self.History(self.report_8k_symbol, 100, Resolution.Daily)
report_10k_history_df = self.History(self.report_10k_symbol, 100, Resolution.Daily)
report_10q_history_df = self.History(self.report_10q_symbol, 100, Resolution.Daily)
history_df = self.History([self.report_8k_symbol,
                           self.report_10k_symbol,
                           self.report_10q_symbol], 100, Resolution.Daily)

# Dataset objects
report_8k_history_bars = self.History[SECReport8K](self.report_8k_symbol, 100, Resolution.Daily)
report_10k_history_bars = self.History[SECReport10K](self.report_10k_symbol, 100, Resolution.Daily)
report_10q_history_bars = self.History[SECReport10Q](self.report_10q_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.report_8k_symbol)
self.RemoveSecurity(self.report_10k_symbol)
self.RemoveSecurity(self.report_10q_symbol)
```

If you subscribe to US SEC Filings data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The US SEC Filings dataset enables you to create strategies using information from SEC reports. Examples include the following strategies:

- Extracting information about corporate earnings from the documents for further analysis
- Applying sentiment analysis to the text content of the documents (for example, keyword scoring and ranking)

Datasets

Smart Insider

Smart Insider was founded by Michael Tindale in 2016 with the goal of forming the most progressive insider data vendor in the field. Smart Insider provides access to buyback intention and transactions for quantitative researchers. In addition to their Corporate Buybacks dataset, Smart Insider provides data on stock trades made by US politicians and thousands of high net worth individuals around the globe.

Corporate Buybacks

Smart Insider

Corporate Buybacks

Introduction

The Corporate Buybacks dataset by Smart Insider tracks US Equities share buyback programs. The data covers 3,000 US Equities, starts in May 2015, and is delivered on a second frequency. This dataset is created by analyzing daily buyback announcements and by using secondary data sources to ensure records are accurate and complete.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Corporate Buybacks dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Smart Insider was founded by Michael Tindale in 2016 with the goal of forming the most progressive insider data vendor in the field. Smart Insider provides access to buyback intention and transactions for quantitative researchers. In addition to their Corporate Buybacks dataset, Smart Insider provides data on stock trades made by US politicians and thousands of high net worth individuals around the globe.

Getting Started

The following snippet demonstrates how to request data from the Corporate Buybacks dataset:

```py
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Minute).Symbol
self.intention_symbol = self.AddData(SmartInsiderIntention, self.symbol).Symbol
self.transaction_symbol = self.AddData(SmartInsiderTransaction, self.symbol).Symbol

self.AddUniverse(SmartInsiderIntentionUniverse, "SmartInsiderIntentionUniverse", Resolution.Daily,
self.IntentionSelection)
self.AddUniverse(SmartInsiderTransactionUniverse, "SmartInsiderTransactionUniverse", Resolution.Daily,
self.TransactionSelection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2015
Asset Coverage	3,000 US Equities
Data Density	Sparse
Resolution	Second
Timezone	New York

Data Point Attributes

The Corporate Buybacks dataset provides **SmartInsiderIntention** , **SmartInsiderIntentionUniverse** , **SmartInsiderTransaction** , and **SmartInsiderTransactionUniverse** objects.

SmartInsiderIntention Attributes

SmartInsiderIntention objects have the following attributes:

SmartInsiderIntentionUniverse Attributes

SmartInsiderIntentionUniverse objects have the following attributes:

SmartInsiderTransaction Attributes

SmartInsiderTransaction objects have the following attributes:

SmartInsiderTransactionUniverse Attributes

SmartInsiderTransactionUniverse objects have the following attributes:

Requesting Data

To add Corporate Buybacks data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
class CorporateBuybacksDataAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2016, 1, 1)
        self.SetEndDate(2021, 1, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Minute).Symbol
        self.intention_symbol = self.AddData(SmartInsiderIntention, self.symbol).Symbol
        self.transaction_symbol = self.AddData(SmartInsiderTransaction, self.symbol).Symbol
```

Accessing Data

To get the current Corporate Buybacks data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.intention_symbol):
        data_point = slice[self.intention_symbol]
        self.Log(f"{self.intention_symbol} intention amount at {slice.Time}: {data_point.Amount}")

    if slice.ContainsKey(self.transaction_symbol):
        data_point = slice[self.transaction_symbol]
        self.Log(f"{self.transaction_symbol} transaction amount at {slice.Time}: {data_point.Amount}")
```

To iterate through all of the dataset objects in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, data_point in slice.Get(SmartInsiderIntention).items():
        self.Log(f"{dataset_symbol} intention amount at {slice.Time}: {data_point.Amount}")

    for dataset_symbol, data_point in slice.Get(SmartInsiderTransaction).items():
        self.Log(f"{dataset_symbol} transaction amount at {slice.Time}: {data_point.Amount}")
```

Historical Data

To get historical Corporate Buybacks data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrames
intention_history_df = self.History(self.intention_symbol, 100, Resolution.Daily)
transaction_history_df = self.History(self.transaction_symbol, 100, Resolution.Daily)
history_df = self.History([self.intention_symbol, self.transaction_symbol], 100, Resolution.Daily)

# Dataset objects
intention_history_bars = self.History[SmartInsiderIntention](self.intention_symbol, 100, Resolution.Daily)
transaction_history_bars = self.History[SmartInsiderTransaction](self.transaction_symbol, 100,
Resolution.Daily)
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Corporate Buybacks data, call the **AddUniverse** method with the **SmartInsiderIntentionUniverse** class or the **SmartInsiderTransactionUniverse** and a selection function.

```
PY
def Initialize(self) -> None:
    self.AddUniverse(SmartInsiderIntentionUniverse, "SmartInsiderIntentionUniverse", Resolution.Daily,
self.IntentionSelection)
    self.AddUniverse(SmartInsiderTransactionUniverse, "SmartInsiderTransactionUniverse", Resolution.Daily,
self.TransactionSelection)

def IntentionSelection(self, alt_coarse: List[SmartInsiderIntentionUniverse]) -> List[Symbol]:
    return [d.Symbol for d in alt_coarse \
                if d.Percentage > 0.005 \
                and d.USDMarketCap > 100000000]

def TransactionSelection(self, alt_coarse: List[SmartInsiderTransactionUniverse]) -> List[Symbol]:
    return [d.Symbol for d in alt_coarse \
                if d.BuybackPercentage > 0.005 \
                and d.USDMarketCap > 100000000]
```

For more information about dynamic universes, see Universes .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

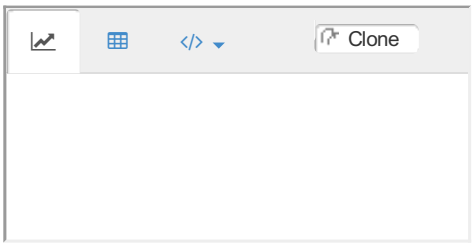
```
PY
self.RemoveSecurity(self.intention_symbol)
self.RemoveSecurity(self.transaction_symbol)
```

If you subscribe to Corporate Buybacks data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Corporate Buybacks dataset enables you to design strategies using information on company buyback programs. Examples include the following strategies:

- Buying securities when the company announces an upcoming share buyback on the premise that the reduction in supply (shares outstanding) will drive up the remaining shares price
- Buying securities when the company executes an upcoming share buyback on the premise that the reduction in supply (shares outstanding) will drive up the remaining shares price



Datasets

Tiingo

Tiingo was founded by Rishi Singh in 2014. Tiingo goes beyond traditional news sources and focuses on finding rich, quality content written by knowledgeable writers. Their proprietary algorithms scan unstructured, non-traditional news and other information sources while tagging companies, topics, and assets. This refined system is backed by over ten years of research and development, and is written by former institutional quant traders. Because of this dedicated approach, Tiingo"s News API is a trusted tool used by quant funds, hedge funds, pension funds, social media companies, and tech companies around the world.

Tiingo News Feed

Tiingo

Tiingo News Feed

Introduction

The Tiingo News Feed dataset by Tiingo tracks US Equity news releases. The data covers 10,000 US Equities, starts in January 2014, and is delivered on a second frequency. This dataset is creating by Tiingo integrating over 120 different news providers into their platform.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Tiingo News Feed dataset, including CLI commands and pricing, see the dataset listing .

Getting Started

The following snippet demonstrates how to request data from the Tiingo News Feed dataset:

```
PY
from QuantConnect.DataSource import *

self.symbol = self.AddEquity("AAPL", Resolution.Minute).Symbol
self.dataset_symbol = self.AddData(TiingoNews, self.symbol).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2014
Asset Coverage	10,000 US Equities
Data Density	Sparse
Resolution	Second
Timezone	UTC

Data Point Attributes

The Tiingo News Feed dataset provides **TiingoNews** objects, which have the following attributes:

Requesting Data

To add Tiingo News Feed data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class TiingoNewsDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1)
        self.SetEndDate(2021, 6, 1)
        self.SetCash(100000)

        self.symbol = self.AddEquity("AAPL", Resolution.Minute).Symbol
        self.dataset_symbol = self.AddData(TiingoNews, self.symbol).Symbol
```

Accessing Data

To get the current Tiingo News Feed data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        article = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} article description at {slice.Time}: {article.Description}")
```

To iterate through all of the articles in the current **Slice** , call the **Get** method.

```
PY
def OnData(self, slice: Slice) -> None:
    for dataset_symbol, article in slice.Get(TiingoNews).items():
        self.Log(f"{dataset_symbol} article description at {slice.Time}: {article.Description}")
```

Historical Data

To get historical Tiingo News Feed data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```py
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
self.History[TiingoNews](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the **RemoveSecurity** method.

```py
self.RemoveSecurity(self.dataset_symbol)
```

If you subscribe to Tiingo News Feed data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Tiingo News Feed enables you to accurately design strategies harnessing news articles on the companies you're trading. Examples include the following strategies:

- Creating a dictionary of sentiment scores for various words and assigning a sentiment score to the content of each news release
- Calculating the sentiment of news releases with Natural Language Processing (NLP)
- Trading securities when their news releases are tagged by Tiingo with current buzzwords

The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

Getting Started

The following snippet demonstrates how to request data from the US Treasury Yield Curve dataset:

```
PY
from QuantConnect.DataSource import *
self.dataset_symbol = self.AddData(USTreasuryYieldCurveRate, "USTYCR").Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1990
Coverage	1 Dataset
Data Density	Sparse
Resolution	Daily
Timezone	New York

Data Point Attributes

The US Treasury Yield Curve dataset provides **USTreasuryYieldCurveRate** objects, which have the following attributes:

Requesting Data

To add US Treasury Yield Curve data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY

class QuiverCongressDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2019, 1, 1)
        self.SetEndDate(2020, 6, 1)
        self.SetCash(100000)

        self.dataset_symbol = self.AddData(USTreasuryYieldCurveRate, "USTYCR").Symbol
```

Accessing Data

To get the current US Treasury Yield Curve data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY

def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} one month value at {slice.Time}: {data_point.OneMonth}")
```

Historical Data

To get historical US Treasury Yield Curve data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY

# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[USTreasuryYieldCurveRate](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to US Treasury Yield Curve data, call the **RemoveSecurity** method.

```
PY

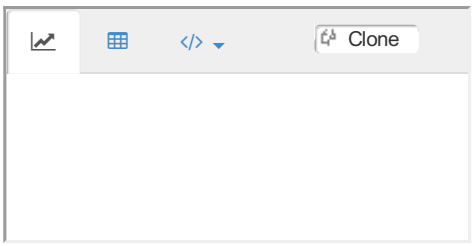
self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The US Treasury Yield Curve dataset enables you to monitor the yields of bonds with numerous maturities in your

strategies. Examples include the following strategies:

- Short selling SPY when the yield curve inverts
- Buying short-term Treasuries and short selling long-term Treasuries when the yield curve becomes steeper (aka curve steepener trade)



Datasets

VIX Central

VIX Central was founded by Eli Mintz in 2012 with goal of displaying historical VIX term structures in a simple and intuitive interface. VIX Central provides access to real-time and historical VIX data for individual investors.

VIX Central Contango

VIX Central

VIX Central Contango

Introduction

The VIX Central Contango dataset by VIX Central tracks VIX Futures (VX) contango data. The data covers 12 Futures contracts closest to expiry/maturity, starts in June 2010, and is delivered on a daily frequency. The dataset is created by QuantConnect downloading data from VIX Central website, which collects and analyses VIX and VX (VIX Futures) data.

Contango and Backwardation are terms used to describe if participants in the Futures market are overpaying or underpaying relative to the "spot" price of the underlying commodity when trading a Futures contract ("spot" price is the price of the actual commodity/asset at a given moment in time). Contango and backwardation can be used to determine forward-looking expectations of the commodity's spot price by the time the Future has expired/matured and is set to be delivered by participants of the Futures market. As Futures near their expiration/maturity date, contango and backwardation curves tend to converge on the spot price of the commodity at the time of expiration.

For more information about the VIX Central Contango dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

VIX Central was founded by Eli Mintz in 2012 with goal of displaying historical VIX term structures in a simple and intuitive interface. VIX Central provides access to real-time and historical VIX data for individual investors.

Getting Started

The following snippet demonstrates how to request data from the VIX Central Contango dataset:

```
PY
from QuantConnect.DataSource import *
self.dataset_symbol = self.AddData(VIXCentralContango, "VIX", Resolution.Daily).Symbol
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	June 2010
Asset Coverage	1 Futures Chain with 12 contracts
Data Density	Regular
Resolution	Daily
Timezone	New York

Data Point Attributes

The VIX Central Contango dataset provides **VIXCentralContango** objects, which have the following attributes:

Requesting Data

To add VIX Central Contango data to your algorithm, call the **AddData** method. Save a reference to the dataset **Symbol** so you can access the data later in your algorithm.

```
PY
class VixCentralContangoAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2014, 1, 1)
        self.SetEndDate(2018, 1, 1)
        self.SetCash(25000)

        self.dataset_symbol = self.AddData(VIXCentralContango, "VX", Resolution.Daily).Symbol
```

Accessing Data

To get the current VIX Central Contango data, index the current **Slice** with the dataset **Symbol** . Slice objects deliver unique events to your algorithm as they happen, but the **Slice** may not contain data for your dataset at every time step. To avoid issues, check if the **Slice** contains the data you want before you index it.

```
PY
def OnData(self, slice: Slice) -> None:
    if slice.ContainsKey(self.dataset_symbol):
        data_point = slice[self.dataset_symbol]
        self.Log(f"{self.dataset_symbol} front month at {slice.Time}: {data_point.FrontMonth}")
```

Historical Data

To get historical VIX Central Contango data, call the **History** method with the dataset **Symbol** . If there is no data in the period you request, the history result is empty.

```
PY
# DataFrame
history_df = self.History(self.dataset_symbol, 100, Resolution.Daily)

# Dataset objects
history_bars = self.History[VIXCentralContango](self.dataset_symbol, 100, Resolution.Daily)
```

For more information about historical data, see History Requests .

Remove Subscriptions

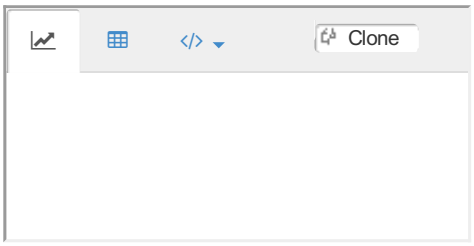
To remove your subscription to VIX Central Contango data, call the **RemoveSecurity** method.

```
self.RemoveSecurity(self.dataset_symbol)
```

Example Applications

The VIX Central Contango dataset enable you to explore VIX Future contracts pricing data. Examples include the following strategies:

- Determining forward-looking expectations by Futures market participants of the underlying commodity's spot price by the time of expiration/maturity
- Creating cash-and-carry arbitrage strategies by trading the spread/convergence of the contango/backwardation curves as a Future nears expiration/maturity



Importing Data

Importing Data

Key Concepts

Introduction

Custom data is your own external data that's not from the Dataset Market. You can use custom data to inform trading decisions and to simulate trades on unsupported securities. To get custom data into your algorithms, you download the entire file at once or read it line-by-line with a custom data reader. If you use a custom data reader, LEAN sends the data to the `OnData` method in your algorithm.

Stream Custom Data

To receive your custom data in the `OnData` method, create a custom type and then create a data subscription. The custom data type tells LEAN where to get your data and how to read it.

All custom data types must extend the `PythonData` class and override the `GetSource` and `Reader` methods

```py
class MyCustomDataType(PythonData):
    def GetSource(self,
                  config: SubscriptionDataConfig,
                  date: datetime,
                  isLive: bool) -> SubscriptionDataSource:
        return SubscriptionDataSource("<sourceURL>", SubscriptionTransportMedium.RemoteFile)

    def Reader(self,
                  config: SubscriptionDataConfig,
                  line: str,
                  date: datetime,
                  isLive: bool) -> BaseData:

                  if not (line.strip() and line[0].isdigit()):
                     return None

                  data = line.split(',')

        custom = MyCustomDataType()
        custom.Time = datetime.strptime(data[0], '%Y%m%d')
        custom.EndTime = custom.Time + timedelta(1)
        custom.Value = float(data[1])
        custom["Property1"] = float(data[2])
        return custom
```

For more information about custom data types, see Streaming Data .

Download Bulk Data

The `Download` method downloads the content served from a local file or URL and then returns it as a string.

```
content = self.Download("<filePathOrURL>")
```

For more information about bulk downloads, see Bulk Downloads .

Remote File Providers

The most common remote file providers to use are Dropbox, GitHub, and Google Sheets.

Dropbox

If you store your custom data in Dropbox, you need to create a link to the file and add `?dl=1` to the end of the file URL. To create file links, see How to share files or folders in the Dropbox documentation. The `?dl=1` parameter lets you download the direct file link, not the HTML page of the file.

GitHub

If you store your custom data in GitHub, you can use public or private repositories. When you download the data, use the raw file (for example, **https://raw.githubusercontent.com/<organization>/<repo>/<path>**). For instructions on accessing the raw file, see Viewing or copying the raw file content in the GitHub documentation.

Google Sheets

If you store your custom data in Google Sheets, you need to create a link to the file. To create file links, see Make Google Docs, Sheets, Slides & Forms public in the Google Docs documentation. Choose the **CSV** format to find `/pub?gid={SHEET_ID}&single=true&output=csv` parameter on the end of the link. Google Sheets don't support exporting data in **JSON** format.

File Quotas

The following table shows the number of files you can download during a single backtest or Research Environment session in QuantConnect Cloud:

Organization Tier	File Quota
Free	25
Quant Researcher	100
Team	250
Trading Firm	1,000
Free	Unlimited

Each file can be up to 200 MB in size and have a file name up to 200 characters long.

If you need to import more files than your quota allows, save your custom data files in the Object Store and load them from there.

Rate Limits

We do not impose a rate limit on file downloads but often external providers do. Dropbox caps download speeds to 10 kb/s after 3-4 download requests. To ensure your algorithms run fast, only use a small number of small custom data files.

Timeouts

In cloud algorithms, the download methods have a 10-second timeout period. If the methods don't download the data within 10 seconds, LEAN throws an error.

Importing Data

Streaming Data

Streaming Data

Key Concepts

Introduction

There are two techniques to import data into your algorithm. You can either manually import the entire file or stream the file line-by-line into your algorithm's `OnData` event. This page explores streaming a file's contents into your algorithm line-by-line.

Data Formats

Common data formats are **CSV** , **JSON** , and **XML** , but you can use any file type that can be read over the internet. Each request has a one-second overhead, so you should package your custom data to minimize requests. Bundle dates together where possible to speed up execution. Just ensure the data in the file is in chronological order.

For Excel files, please double check the raw data format for parsing in the data reader, since data will be formatted for convenient visualization in Excel application view. To avoid confusion of data format, save the spreadsheet as a **CSV** file and open it in a text editor to confirm the raw data format.

Set Data Sources

The `GetSource` method in your custom data class instructs LEAN where to find the data. This method must return a `SubscriptionDataSource` object, which contains the data location and format.

The following table describes the arguments the `SubscriptionDataSource` accepts:

Argument	Data Type	Description	Default Value
source	str	Data source location	
transportMedium	SubscriptionTransportMedium	The transport medium to be used to retrieve data from the source	
format	FileFormat	The format of the data within the source	FileFormat.Csv
headers	IEnumerable<KeyValuePair<string, string>>	The headers to be used for this source. In cloud algorithms, each of the key-value pairs can consist of up to 1,000 characters.	None

The SubscriptionTransportMedium enumeration has the following members:

The FileFormat enumeration has the following members:

The following table describes the arguments the GetSource method accepts:

Argument	Data Type	Description
config	SubscriptionDataConfig	The subscription configuration
date	datetime	Date of this source file
isLiveMode	bool	True if algorithm is running in live mode

You can use these arguments to create SubscriptionDataSource objects representing different locations and formats.

```
class MyCustomDataType(PythonData):
    def GetSource(self,
         config: SubscriptionDataConfig,
         date: datetime,
         isLiveMode: bool) -> SubscriptionDataSource:

         if isLiveMode:
            return SubscriptionDataSource("https://www.bitstamp.net/api/ticker/",
SubscriptionTransportMedium.Rest)

        source = f"http://my-ftp-server.com/{config.Symbol.Value}/{date:%Y%M%d}.csv"
        return SubscriptionDataSource(source, SubscriptionTransportMedium.RemoteFile)
```

Parse Custom Data

The Reader method of your custom data class takes one line of data from the source location and parses it into one of your custom objects. You can add as many properties to your custom data objects as you need, but the following table describes the properties you must set. When there is no useable data in a line, the method should return None . LEAN repeatedly calls the Reader method until the date/time advances or it reaches the end of the file.

Property	Description
`Symbol`	You can set this property to `config.Symbol` .
`Time`	The time when the data sample starts.
`EndTime`	The time when the data sample ends and when LEAN should add the sample to a Slice .
`Value`	The default data point value.

The following table describes the arguments the `Reader` method accepts:

Argument	Data Type	Description
`config`	`SubscriptionDataConfig`	The subscription configuration
`line`	`str`	Content from the requested data source
`date`	`datetime`	Date of this source file
`isLiveMode`	`bool`	`True` if algorithm is running in live mode

You can use these arguments to create `BaseData` objects from different sources.

```
class MyCustomDataType(PythonData):
    def Reader(self,
         config: SubscriptionDataConfig,
         line: str,
         date: datetime,
         isLiveMode: bool) -> BaseData:

        if not line.strip():
            return None

        custom = MyCustomDataType()
        custom.Symbol = config.Symbol

        if isLiveMode:
            data = json.loads(line)
            custom.EndTime =  Extensions.ConvertFromUtc(datetime.utcnow(), config.ExchangeTimeZone)
            custom.Value = data["value"]
            return custom

        if not line[0].isdigit():
            return None

        data = line.split(',')
        custom.EndTime = datetime.strptime(data[0], '%Y%m%d') + timedelta(1)
        custom.Value = float(data[1])
        return custom
```

Demonstration Algorithm

The following example algorithm implements a custom data source for the Bitstamp API.

```
class CustomDataBitstampAlgorithm(QCAlgorithm):
```

```
    def Initialize(self):
        self.SetStartDate(2012, 9, 13)
        self.SetEndDate(2021, 6, 20)
        self.SetCash(100000)

        # Define the symbol and "type" of our generic data:
        self.custom_data_symbol = self.AddData(Bitstamp, "BTC").Symbol

        history = self.History(Bitstamp, self.custom_data_symbol, 200, Resolution.Daily)
        self.Debug(f"We got {len(history)} items from historical data request of
{self.custom_data_symbol}.")

    def OnData(self, slice):
        if self.custom_data_symbol not in slice:
            return

        data = slice[self.custom_data_symbol]
        self.Log(f'{data.EndTime}: Close: {data.Close}')
        self.Plot(self.custom_data_symbol, 'Price', data.Close)

class Bitstamp(PythonData):

    def GetSource(self, config, date, isLiveMode):
        if isLiveMode:
            return SubscriptionDataSource("https://www.bitstamp.net/api/ticker/",
SubscriptionTransportMedium.Rest)

        source =
"https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/bitstampusd.csv"
        return SubscriptionDataSource(source, SubscriptionTransportMedium.RemoteFile)

    def Reader(self, config, line, date, isLiveMode):

        if not line.strip():
            return None

        coin = Bitstamp()
        coin.Symbol = config.Symbol

        if isLiveMode:
            # Example Line Format:
            # {"high": "441.00", "last": "421.86", "timestamp": "1411606877", "bid": "421.96", "vwap":
"428.58", "volume": "14120.40683975", "low": "418.83", "ask": "421.99"}
            liveBTC = json.loads(line)

            # If value is zero, return None
            coin.Value = float(liveBTC["last"])
            if coin.Value == 0:
                return None

            coin.EndTime =  Extensions.ConvertFromUtc(datetime.utcnow(), config.ExchangeTimeZone)
            coin.Time = coin.EndTime - timedelta(1)
            coin["Open"] = float(liveBTC["open"])
            coin["High"] = float(liveBTC["high"])
            coin["Low"] = float(liveBTC["low"])
            coin["Close"] = coin.Value
            coin["Ask"] = float(liveBTC["ask"])
            coin["Bid"] = float(liveBTC["bid"])
            coin["VolumeBTC"] = float(liveBTC["volume"])
            coin["WeightedPrice"] = float(liveBTC["vwap"])
            return coin

        # Example Line Format:
        # Date      Open   High    Low     Close   Volume (BTC)    Volume (Currency)   Weighted Price
        # 2011-09-13 5.8    6.0     5.65    5.97    58.37138238,    346.0973893944      5.929230648356
        if not line[0].isdigit():
            return None

        data = line.split(',')

        # If value is zero, return None
        coin.Value = float(data[4])
        if coin.Value == 0:
            return None

        coin.Time = datetime.strptime(data[0], "%Y-%m-%d")
        coin.EndTime = coin.Time + timedelta(1)
```

```
        coin.EndTime = coin.Time + timedelta(1)
        coin["Open"] = float(data[1])
        coin["High"] = float(data[2])
        coin["Low"] = float(data[3])
        coin["Close"] = coin.Value
        coin["VolumeBTC"] = float(data[5])
        coin["VolumeUSD"] = float(data[6])
        coin["WeightedPrice"] = float(data[7])
        return coin
```

To save this algorithm to your cloud projects, clone it .

Streaming Data

Custom Securities

Custom Securities

Key Concepts

Introduction

To receive your custom data in the `OnData` method instead of in a bulk download, create a custom type and then create a data subscription. The custom data type tells LEAN where to get your data and how to read it. All custom data types must extend from `PythonData` and override the `Reader` and `GetSource` methods.

Unlike custom data, native QC data gets the full benefit of security modeling like splits and dividends. Custom data is ignorant of everything about the actual market. Things like market hours, delistings, and mergers don't work with custom data.

Create Subscriptions

After you define the custom data class, in the `Initialize` method of your algorithm, call the `self.AddData(Type class, string ticker, Resolution resolution = Resolution.Daily)` method. This method gives LEAN the type factory to create the data objects, the name of the data, and the resolution to poll the data source for updates.

```
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddData(MyCustomDataType, "<name>", Resolution.Daily).Symbol
```

The `resolution` argument should match the resolution of your custom dataset. The lowest reasonable resolution is every minute. Anything more frequent than every minute is very slow to execute. The frequency that LEAN checks the data source depends on the `resolution` argument. The following table shows the polling frequency of each resolution:

Resolution	Update Frequency
Daily	Every 30 minutes
Hour	Every 30 minutes
Minute	Every minute
Second	Every second
Tick	Constantly checks for new data

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `OnData` method. To collect the custom data, use the `Symbol` or name of your custom data subscription. You can access the `Value` and custom properties of your custom data class from the `Slice` . To access the custom properties, pass the property name to the `GetProperty` method .

```
PY
class MyAlgorithm(QCAlgorithm):
    def OnData(self, slice: Slice) -> None:
        if slice.ContainsKey(self.symbol):
            custom_data = slice[self.symbol]
            value = custom_data.Value
            property1 = custom_data.Property1
```

Set the Benchmark

To set your custom data source as the benchmark, in the `Initialize` method, call the `SetBenchmark` method with the `Symbol` of your custom data subscription.

```
PY
self.symbol = self.AddData(MyCustomDataType, "<name>", Resolution.Daily).Symbol
self.SetBenchmark(self.symbol)
```

Avoid Look-Ahead Bias

Look-ahead bias occurs when you make decisions with information that wouldn't be available until some time in the future. In backtesting, look-ahead bias occurs when you receive data earlier than it would actually be available in reality. If look-ahead bias seeps into your algorithm, it will perform differently between live trading and backtesting.

To avoid look-ahead bias, set the timestamp of data points to the time when the data would actually be available. A lot of external sources apply timestamps to data differently than we do. For instance, on some platforms, daily bars are displayed with the date that they opened. We display daily bars with the date they closed. If you set the `EndTime` to the start of the bar, you'll receive the bar earlier in backtests than you would in live trading.

Time Modeling

Data types classes in LEAN inherit from the `BaseData` class that defines the `Time` and `EndTime` properties. These properties represent the time period of which the data was built. If the data type occurs in a singular point in time, they

have no period, so `Time` and `EndTime` are the same. Regardless of the period, LEAN uses the time when the data sample ends, `EndTime` , to add the sample to a `Slice` .

Custom Securities

CSV Format Example

Introduction

This page explains how to import custom data of a single security sourced in **CSV** format.

Data Format

The following snippet shows an example **CSV** file:

```
Date,Open,High,Low,Close,SharesTraded,Tur11er(Rs.Cr)
1997-01-01,905.2,941.4,905.2,939.55,38948210,978.21
1997-01-02,941.95,944,925.05,927.05,49118380,1150.42
1997-01-03,924.3,932.6,919.55,931.65,35263845,866.74
...
2014-07-24,7796.25,7835.65,7771.65,7830.6,117608370,6271.45
2014-07-25,7828.2,7840.95,7748.6,7790.45,153936037,7827.61
2014-07-28,7792.9,7799.9,7722.65,7748.7,116534670,6107.78
```

The data in the file must be in chronological order.

Define Custom Types

To define a custom data type, inherit the `PythonData` class and override the GetSource and Reader methods.

```
PY
class MyCustomDataType(PythonData):

    def GetSource(self,
         config: SubscriptionDataConfig,
         date: datetime,
         isLive: bool) -> SubscriptionDataSource:
        return SubscriptionDataSource("https://www.dropbox.com/s/rsmg44jr6wexn2h/CNXNIFTY.csv?dl=1",
SubscriptionTransportMedium.RemoteFile)

    def Reader(self,
         config: SubscriptionDataConfig,
         line: str,
         date: datetime,
         isLive: bool) -> BaseData:

        if not (line.strip()):
            return None

        index = MyCustomDataType()
        index.Symbol = config.Symbol

        try:
            data = line.split(',')
            index.Time = datetime.strptime(data[0], "%Y-%m-%d")
            index.EndTime = index.Time + timedelta(days=1)
            index.Value = data[4]
            index["open"] = float(data[1])
            index["high"] = float(data[2])
            index["low"] = float(data[3])
            index["close"] = float(data[4])

        except ValueError:
            # Do nothing
            return None

        return index
```

Create Subscriptions

To create a subscription for the custom type, in the `Initialize` method, call the `AddData` method. The `AddData` method returns a `Security` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
PY
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddData(MyCustomDataType, "MyCustomDataType", Resolution.Daily).Symbol
```

The `AddData` method creates a subscription for a single custom data asset and adds it to your **user-defined** universe.

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `OnData` method. To collect the custom data, use the `Symbol` or name of your custom data subscription. You can access the `Value` and custom properties of your custom data class from the `Slice` . To access the custom properties, pass the property name to the `GetProperty` method .

```
class MyAlgorithm(QCAlgorithm):
    def OnData(self, slice: Slice) -> None:
        if slice.ContainsKey(self.symbol):
            custom_data = slice[self.symbol]
            close = custom_data.Close
```

If you add custom properties to your data object in the `Reader` method, LEAN adds them as members to the data object in the `Slice` . To ensure the property names you add in the `Reader` method follow the convention of member names, LEAN applies the following changes to the property names you provide in the `Reader` method:

1. `-` and `.` characters are replaced with whitespace.
2. The first letter is capitalized.
3. Whitespace characters are removed.

For example, if you set a property name in the `Reader` method to `['some-property.name']` , you can access it in the `OnData` method through the `Somepropertyname` member of your data object.

Custom Securities

JSON Format Example

Introduction

This page explains how to import custom data of a single security sourced in **JSON** format.

Data Format

The following code snippet shows an example **JSON** file

```
[
    {
      "Date": "1997-01-01",
      "Open": 905.2,
      "High": 941.4,
      "Low": 905.2,
      "Close": 939.55,
      "SharesTraded": 38948210,
      "Tur11er(Rs.Cr)": 978.21
    },
    {
      "Date": "1997-01-02",
      "Open": 941.95,
      "High": 944,
      "Low": 925.05,
      "Close": 927.05,
      "SharesTraded": 49118380,
      "Tur11er(Rs.Cr)": 1150.42
    },
    ...
    {
      "Date": "2014-07-25",
      "Open": 7828.2,
      "High": 7840.95,
      "Low": 7748.6,
      "Close": 7790.45,
      "SharesTraded": 153936037,
      "Tur11er(Rs.Cr)": 7827.61
    },
    {
      "Date": "2014-07-28",
      "Open": 7792.9,
      "High": 7799.9,
      "Low": 7722.65,
      "Close": 7748.7,
      "SharesTraded": 116534670,
      "Tur11er(Rs.Cr)": 6107.78
    }
]
```

The data in the file must be in chronological order.

Define Custom Types

To define a custom data type, inherit the `PythonData` class and override the GetSource and Reader methods.

If you need to create multiple objects in your `Reader` method from a single `line` , follow these steps:

1. In the `GetSource` method, pass `FileFormat.UnfoldingCollection` as the third argument to the

`SubscriptionDataSource` constructor.

2. In the `Reader` method, order the objects by their timestamp and then return a `BaseDataCollection(endTime, config.Symbol, objects)` where `objects` is a list of your custom data objects.

```
class MyCustomDataType(PythonData):
    def GetSource(self,
         config: SubscriptionDataConfig,
         date: datetime,
         isLive: bool) -> SubscriptionDataSource:
        return
SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/
data/unfolding-collection-example.json", SubscriptionTransportMedium.RemoteFile,
FileFormat.UnfoldingCollection)

    def Reader(self,
         config: SubscriptionDataConfig,
         line: str,
         date: datetime,
         isLive: bool) -> BaseData:

        if not (line.strip()):
            return None

        objects = []
        data = json.loads(line)

        for datum in data:
            index = MyCustomDataType()
            index.Symbol = config.Symbol
            index.Time = datetime.strptime(datum["Date"], "%Y-%m-%d")
            index.EndTime = index.Time + timedelta(1)
            index["Open"] = float(datum["Open"])
            index["High"] = float(datum["High"])
            index["Low"] = float(datum["Low"])
            index["Close"] = float(datum["Close"])
            index.Value = index["Close"]
            objects.append(index)

        return BaseDataCollection(objects[-1].EndTime, config.Symbol, objects)
```

Create Subscriptions

To create a subscription for the custom type, in the `Initialize` method, call the `AddData` method. The `AddData` method returns a `Security` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddData(MyCustomDataType, "MyCustomDataType", Resolution.Daily).Symbol
```

The `AddData` method creates a subscription for a single custom data asset and adds it to your **user-defined** universe.

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `OnData` method. To collect the custom data, use the `Symbol` or name of your custom data subscription. You can access the `Value` and custom properties of your custom data class from the `Slice` . To access the custom properties, pass the property name to the `GetProperty` method .

```
class MyAlgorithm(QCAlgorithm):
    def OnData(self, slice: Slice) -> None:
        if slice.ContainsKey(self.symbol):
            custom_data = slice[self.symbol]
            close = custom_data.Close
```

If you add custom properties to your data object in the `Reader` method, LEAN adds them as members to the data object in the `Slice` . To ensure the property names you add in the `Reader` method follow the convention of member names, LEAN applies the following changes to the property names you provide in the `Reader` method:

1. `-` and `.` characters are replaced with whitespace.
2. The first letter is capitalized.
3. Whitespace characters are removed.

For example, if you set a property name in the `Reader` method to `['some-property.name']` , you can access it in the `OnData` method through the `Somepropertyname` member of your data object.

Custom Universes

Custom Universes

Key Concepts

Introduction

A custom universe lets you select a basket of assets from a custom dataset.

Initialize Universes

To add a custom universe to your algorithm, in the `Initialize` method, pass your universe type and a selector function to the `AddUniverse` method.

```
PY
self.AddUniverse(MyCustomUniverseDataClass, "myCustomUniverse", Resolution.Daily, self.selector_function)
```

Receive Custom Data

The universe selector function receives a list of your custom objects and must return a list of `Symbol` objects. In the selector function definition, you can use any of the properties of your custom data type. The `Symbol` objects that you return from the selector function set the constituents of the universe.

```
PY
class MyCustomUniverseAlgorithm(QCAlgorithm):
 def selector_function(self, data: List[MyCustomUniverseDataClass]) -> List[Symbol]:
     sorted_data = sorted([ x for x in data if x["CustomAttribute1"] > 0 ],
                          key=lambda x: x["CustomAttribute2"],
                          reverse=True)
     return [x.Symbol for x in sorted_data[:5]]
```

Custom Universes

CSV Format Example

Introduction

This page explains how to import custom data for universe selection sourced in **CSV** format.

Data Format

You must create a file with data in **CSV** format. Ensure the data in the file is in chronological order.

```
20170704,SPY,QQQ,FB,AAPL,IWM
20170706,QQQ,AAPL,IWM,FB,GOOGL
20170707,IWM,AAPL,FB,BAC,GOOGL
...
20170729,SPY,QQQ,FB,AAPL,IWM
20170801,QQQ,FB,AAPL,IWM,GOOGL
20170802,QQQ,IWM,FB,BAC,GOOGL
```

Define Custom Types

To define a custom data type, inherit the `PythonData` class and override the GetSource and Reader methods.

PY

```
class StockDataSource(PythonData):

    def GetSource(self,
                  config: SubscriptionDataConfig,
                  date: datetime,
                  isLive: bool) -> SubscriptionDataSource:
        return SubscriptionDataSource("https://www.dropbox.com/s/ae1couew5ir3z9y/daily-stock-picker-
backtest.csv?dl=1", SubscriptionTransportMedium.RemoteFile)

    def Reader(self,
                  config: SubscriptionDataConfig,
                  line: str,
                  date: datetime,
                  isLive: bool) -> BaseData:

        if not (line.strip() and line[0].isdigit()): return None

        stocks = StockDataSource()
        stocks.Symbol = config.Symbol

        try:
            csv = line.split(',')
            stocks.Time = datetime.strptime(csv[0], "%Y%m%d")
            stocks.EndTime = stocks.Time + timedelta(days=1)
            stocks["Symbols"] = csv[1:]

        except ValueError:
            # Do nothing
            return None

        return stocks
```

Initialize Universe

To perform a universe selection with custom data, in the `Initialize` method, call the `AddUniverse` method.

```
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.AddUniverse(StockDataSource, "my-stock-data-source", Resolution.Daily, self.FilterFunction)
```

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points into a `List[StockDataSource])` object it passes to your algorithm's filter function. Your filter function needs to return a list of `Symbol` or `str` object. LEAN automatically subscribes to these new assets and adds them to your algorithm.

```
class MyAlgorithm(QCAlgorithm):
    def FilterFunction(self, data: List[StockDataSource]) -> List[str]:
        list = []
        for item in data:
            for symbol in item["Symbols"]:
                list.append(symbol)
        return list
```

If you add custom properties to your data object in the `Reader` method, LEAN adds them as members to the data object in your filter method. To ensure the property names you add in the `Reader` method follow the convention of member names, LEAN applies the following changes to the property names you provide in the `Reader` method:

1. `-` and `.` characters are replaced with whitespace.
2. The first letter is capitalized.
3. Whitespace characters are removed.

For example, if you set a property name in the `Reader` method to `['some-property.name']` , you can access it in your filter method through the `Somepropertyname` member of your data object.

Custom Universes

JSON Format Example

Introduction

This page explains how to import custom data for universe selection sourced in **JSON** format.

Data Format

You must create a file with data in **JSON** format. Ensure the data in the file is in chronological order.

```
[
    {
      "Date": "20170704",
      "Symbols": ["SPY", "QQQ", "FB", "AAPL", "IWM"]
    },
    {
      "Date": "20170706",
      "Symbols": ["QQQ", "AAPL", "IWM", "FB", "GOOGL"]
    },
    ...
    {
      "Date": "20170801",
      "Symbols": ["QQQ", "FB", "AAPL", "IWM", "GOOGL"]
    },
    {
      "Date": "20170802",
      "Symbols": ["QQQ", "IWM", "FB", "BAC", "GOOGL"]
    }
]
```

Define Custom Types

To define a custom data type, inherit the `PythonData` class and override the GetSource and Reader methods.

If you need to create multiple objects in your `Reader` method from a single `line` , follow these steps:

1. In the `GetSource` method, pass `FileFormat.UnfoldingCollection` as the third argument to the `SubscriptionDataSource` constructor.
2. In the `Reader` method, order the objects by their timestamp and then return a `BaseDataCollection(endTime, config.Symbol, objects)` where `objects` is a list of your custom data objects.

```
class StockDataSource(PythonData):

    def GetSource(self,
         config: SubscriptionDataConfig,
         date: datetime,
         isLive: bool) -> SubscriptionDataSource:
        return SubscriptionDataSource("https://www.dropbox.com/s/7xe7lfac52mdfpe/custom-universe.json?
dl=1",
                                      SubscriptionTransportMedium.RemoteFile,
                                      FileFormat.UnfoldingCollection)

    def Reader(self,
         config: SubscriptionDataConfig,
         line: str,
         date: datetime,
         isLive: bool) -> BaseData:

        objects = []
        data = json.loads(line)

        for datum in data:
            stocks = StockDataSource()
            stocks.Symbol = config.Symbol

            stocks.Time = datetime.strptime(datum["Date"], "%Y%m%d")
            stocks.EndTime = stocks.Time + timedelta(1)
            stocks["Symbols"] = datum["Symbols"]
            objects.append(stocks)

        return BaseDataCollection(objects[-1].EndTime, config.Symbol, objects)
```

Initialize Universe

To perform a universe selection with custom data, in the `Initialize` method, call the `AddUniverse` method.

```
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.AddUniverse(StockDataSource, "my-stock-data-source", Resolution.Daily, self.FilterFunction)
```

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points into a `List[StockDataSource])` object it passes to your algorithm's filter function. Your filter function needs to return a list of `Symbol` or `str` object. LEAN automatically subscribes to these new assets and adds them to your algorithm.

```
class MyAlgorithm(QCAlgorithm):
    def FilterFunction(self, data: List[StockDataSource]) -> List[str]:
        list = []
        for item in data:
            for symbol in item["Symbols"]:
                list.append(symbol)
        return list
```

If you add custom properties to your data object in the `Reader` method, LEAN adds them as members to the data object in your filter method. To ensure the property names you add in the `Reader` method follow the convention of member names, LEAN applies the following changes to the property names you provide in the `Reader` method:

1. `-` and `.` characters are replaced with whitespace.

2. The first letter is capitalized.
3. Whitespace characters are removed.

For example, if you set a property name in the `Reader` method to `['some-property.name']` , you can access it in your filter method through the `Somepropertyname` member of your data object.

Demonstration Algorithms

DropboxBaseDataUniverseSelectionAlgorithm.py Python

Importing Data

Bulk Downloads

Introduction

There are two techniques to import data into your algorithm. You can either manually import the entire file or stream the file line-by-line into your algorithm's `OnData` event. This page explores importing an entire file for manual use.

Recommended Use Cases

The batch import technique is outside of the LEAN's awareness or control, so it can't enforce good practices. However, the batch import technique is good for the loading the following datasets:

- Trained AI Models
- Well-defined historical price datasets
- Parameters and setting imports such as `Symbol` lists

Download Files

The `Download` method downloads the content served from a local file or URL and then returns it as a string.

Basic Usage

```py
file = self.Download("<filePathOrURL>")

# If your file is in CSV format, convert it to a DataFrame with the `read_csv` method.
from io import StringIO
import pandas as pd
df = pd.read_csv(StringIO(file))

# If your file is in JSON format, parse it with the `loads` method.
import json
data = json.loads(file)

# If your file is in XML format, parse it with the `fromstring` method.
import xml.etree.ElementTree as ET
root = ET.fromstring(file)
```

Download Method Arguments

The `Download` method can accept header settings, a username, and a password for authentication.

Argument	Data Type	Description	Default Value
address	str	A string containing the URI to download	
headers	Dict[str,str]	Defines header values to add to the request	dict()
userName	str	The user name associated with the credentials	None
password	str	The password for the user name associated with the credentials	None

Download Request Headers

```
header = { "1": "1" }
self.Download(address, headers)
self.Download(address, headers, user_name, password)
```

Transport Binary Data

Follow these steps to transport binary files:

1. Add the following imports to your program:

```
import pickle
import base64
```

2. Serialize your object.

```
pickle_bytes = pickle.dumps(my_object)
base64_str = base64.b64encode(pickle_bytes).decode('ascii')
```

3. Save the string representation of your object into the ObjectStore or one of the supported external sources .
4. Load the string representation of your object into your trading algorithm.
5. Restore the object.

```
base64_bytes = base64_str.encode('ascii')
model = base64.b64decode(base64_bytes)
restored_model = pickle.loads(model)
```

Consolidating Data

Consolidating Data

Getting Started

Introduction

Consolidating data allows you to create bars of any length from smaller bars. Consolidation is commonly used to combine one-minute price bars into longer bars such as 10-20 minute bars. Consolidated bars are helpful because price movement over a longer period can sometimes contain less noise and bars of exotic length are less researched than standard bars, so they may present more opportunities to capture alpha.

To consolidate data, create a `Consolidator` object and register it for data. The built-in consolidators make it easy to create consolidated bars without introducing bugs. In the following sections, we will introduce the different types of consolidators and show you how to shape data into any form.

Basic Usage

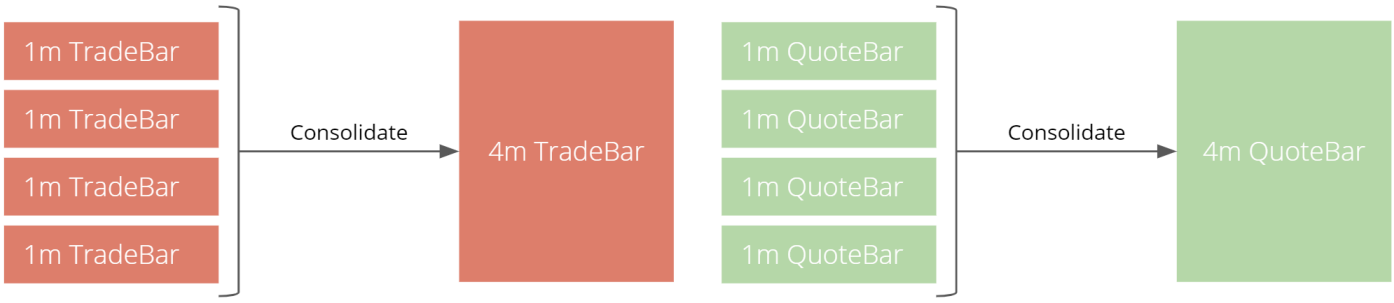
The following code snippet demonstrates a simple consolidator that aggregates 1-minute bars into 10-minutes bars:

```
# In Initialize, subscribe to a security, create the consolidator, and register it for automatic updates
self.symbol = self.AddEquity("SPY", Resolution.Minute).Symbol
self.consolidator = self.Consolidate(self.symbol, timedelta(minutes=10), self.consolidation_handler)

# Define the consolidation handler
def consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Data Shapes and Sizes

Consolidators usually produce output data that is the same format as the input data. They aggregate small `TradeBar` objects into a large `TradeBar` , small `QuoteBar` objects into a large `QuoteBar` , and `Tick` objects into either a `TradeBar` or `QuoteBar` .



Many asset classes in QuantConnect have data for both trades and quotes. By default, consolidators aggregate data

into `TradeBar` objects. Forex data is the only exception, which consolidators aggregate into `QuoteBar` objects since Forex data doesn't have `TradeBar` objects.

Consolidator Types

There are many different types of consolidators you can create. The process to create and update the consolidator depends on the input data format, output data format, and the consolidation technique.

Time Period Consolidators

Time period consolidators aggregate data based on a period of time like a number of seconds, minutes, or days. If a time period consolidator aggregates data over multiple days, the multi-day aggregation cycle starts and repeats based on the time stamp of the first data point you use to update the consolidator.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Calendar Consolidators

Calendar consolidators aggregate data based on specific periods of time like a weekly basis, quarterly basis, or any schedule with specific start and end times. In contrast to time period consolidators, the bars that calendar consolidators produce always end on the same schedule, regardless of the first data point the consolidator receives.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Count Consolidators

Count consolidators aggregate data based on a number of bars or ticks. This type of consolidator aggregates **n** samples together, regardless of the time period the samples cover. Managing count consolidators is similiar to managing time period consolidators , except you create count consolidators with an integer argument instead of a time-based argument.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Mixed-Mode Consolidators

Mixed-mode consolidators are a combination of count consolidators and time period consolidators. This type of consolidator aggregates **n** samples together or aggregates samples over a specific time period, whichever happens first.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Renko Consolidators

Most Renko consolidators aggregate bars based on a fixed price movement. The `RenkoConsolidator` produces Renko bars by their traditional definition. In the case of a $1 bar size, the `RenkoConsolidator` produces bars that have a body spanning 1.*Theopeningpriceofthefirstbarissettotheclosest*1 multiple of the first trade. When the price moves by at least 1, *thefirstbarcloses*. *Ifabarisarisingbar*, *thefollowingbarcloseswhenthepricemoves*1 above the closing price of the previous bar or 1*belowtheopeningpriceofthepreviousbar*. *Ifabarisafallingbar*, *thefollowingbarcloseswhenthepricemoves*1 below the closing price of the previous bar or $1 above the opening price of the previous bar. If the price jumps multiple dollars in a single tick, the `RenkoConsolidator` produces multiple $1 bars in a single time step.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	RenkoConsolidator
`QuoteBar`	`QuoteBar`	RenkoConsolidator
`Tick`	`TradeBar`	RenkoConsolidator
`Tick`	`QuoteBar`	RenkoConsolidator

Classic Renko Consolidators

Most Renko consolidators aggregate bars based on a fixed price movement. The `ClassicRenkoConsolidator` produces a different type of Renko bars than the `RenkoConsolidator` . A `ClassicRenkoConsolidator` with a bar size of 1*producesanewbarthatspans*1 every time an asset closes $1 away from the close of the previous bar. If the price jumps multiple dollars in a single tick, the `ClassicRenkoConsolidator` only produces one bar per time step where the open of each bar matches the close of the previous bar.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	ClassicRenkoConsolidator
`QuoteBar`	`QuoteBar`	ClassicRenkoConsolidator
`Tick`	`TradeBar`	ClassicRenkoConsolidator
`Tick`	`QuoteBar`	ClassicRenkoConsolidator

Volume Renko Consolidators

Volume Renko consolidators aggregate bars based on a fixed trading volume. These types of bars are commonly known as volume bars. A `VolumeRenkoConsolidator` with a bar size of 10,000 produces a new bar every time 10,000 units of the security trades in the market. If the trading volume of a single time step exceeds two step sizes (i.e. >20,000), the `VolumeRenkoConsolidator` produces multiple bars in a single time step.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	VolumeRenkoConsolidator
`Tick`	`TradeBar`	VolumeRenkoConsolidator

Sequential Consolidators

Sequential consolidators wire two internal consolidators together such that the output of the first consolidator is the input to the second consolidator and the output of the second consolidator is the output of the sequential consolidator.

For more information about sequential consolidators, see Combining Consolidators .

Execution Sequence

The algorithm manager calls events in the following order:

1. Scheduled Events
2. Consolidation event handlers
3. `OnData` event handler

This event flow is important to note. For instance, if your consolidation handlers or `OnData` event handler appends data

to a `RollingWindow` and you use that `RollingWindow` in your Scheduled Event, when the Scheduled Event executes, the `RollingWindow` won't contain the most recent data.

The consolidators are called in the order that they are updated. If you register them for automatic updates, they are updated in the order that you register them.

Consolidating Data

Consolidator Types

Consolidator Types

Time Period Consolidators

Introduction

Time period consolidators aggregate data based on a period of time like a number of seconds, minutes, or days. If a time period consolidator aggregates data over multiple days, the multi-day aggregation cycle starts and repeats based on the time stamp of the first data point you use to update the consolidator.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

- `timedelta` Periods

```
self.consolidator = TradeBarConsolidator(timedelta(days=1))
# Aliases:
# self.consolidator = self.CreateConsolidator(timedelta(days=1), TradeBar)
# self.consolidator = self.ResolveConsolidator(self.symbol, timedelta(days=1))
```

  The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

- `Resolution` Periods

  The `Resolution` enumeration has the following members:

```
self.consolidator = TradeBarConsolidator.FromResolution(Resolution.Daily)
# Alias:
# self.consolidator = self.ResolveConsolidator(self.symbol, Resolution.Daily)
```

If the security subscription in your algorithm provides `TradeBar` and `QuoteBar` data, `ResolveConsolidator` returns a `TradeBarConsolidator` .

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone . If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at 9:31 AM Eastern Time (ET). The consolidated bar for US Equities doesn't close at 4:00 PM ET because the day isn't over. The consolidated bar for US Equities also doesn't close at midnight because your algorithm doesn't receive minute resolution data after 4:00 PM ET until 9:31 AM ET.

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    trade_bar = slice.Bars[self.symbol]
    self.consolidator.Update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[TradeBar](self.symbol, 30, Resolution.Minute)
for trade_bar in history:
    self.consolidator.Update(trade_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

```
self.consolidator = self.Consolidate(self.symbol, timedelta(days=1), self.consolidation_handler)
```

- `Resolution` Periods

```
self.consolidator = self.Consolidate(self.symbol, Resolution.Daily, self.consolidation_handler)
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

- `timedelta` Periods

```
self.consolidator = QuoteBarConsolidator(timedelta(days=1))
# Aliases:
# self.consolidator = self.CreateConsolidator(timedelta(days=1), QuoteBar)
# self.consolidator = self.ResolveConsolidator(self.symbol, timedelta(days=1))
```

  The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

- `Resolution` Periods

  The `Resolution` enumeration has the following members:

```
self.consolidator = self.ResolveConsolidator(self.symbol, Resolution.Daily)
```

If the security subscription in your algorithm provides `TradeBar` and `QuoteBar` data, `ResolveConsolidator` returns a `TradeBarConsolidator` .

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone . If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at 9:31 AM Eastern Time (ET). The consolidated bar for US Equities doesn't close at 4:00 PM ET because the day isn't over. The consolidated bar for US Equities also doesn't close at midnight because your algorithm doesn't receive minute resolution data after 4:00 PM ET until 9:31 AM ET.

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```
  PY

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      quote_bar = slice.QuoteBars[self.symbol]
      self.consolidator.Update(quote_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.History[QuoteBar](self.symbol, 30, Resolution.Minute)
  for quote_bar in history:
      self.consolidator.Update(quote_bar)
  ```
  PY

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```
PY

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

  ```
  self.consolidator = self.Consolidate(self.symbol, timedelta(days=1), TickType.Quote,
  self.consolidation_handler)
  ```
  PY

- `Resolution` Periods

```
self.consolidator = self.Consolidate(self.symbol, Resolution.Daily, TickType.Quote,
self.consolidation_handler)
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: QuoteBar) -> None:
    pass
```

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

- `timedelta` Periods

  ```
  self.consolidator = TickConsolidator(timedelta(milliseconds=100))
  # Aliases:
  # self.consolidator = self.CreateConsolidator(timedelta(milliseconds=100), Tick)
  # self.consolidator = self.ResolveConsolidator(self.symbol, timedelta(milliseconds=100))
  ```

  The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

- `Resolution` Periods

  The `Resolution` enumeration has the following members:

  ```
  self.consolidator = self.ResolveConsolidator(self.symbol, Resolution.Second)
  ```

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the

consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
PY
def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone . If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars milliseconds after 9:30 AM Eastern Time (ET). The consolidated bar for US Equities doesn't close at 4:00 PM ET because the day isn't over. The consolidated bar for US Equities also doesn't close at midnight because your algorithm doesn't receive minute resolution data after 4:00 PM ET until milliseconds after 9:30 AM ET.

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  PY
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  PY
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      ticks = slice.Ticks[self.symbol]
      for tick in ticks:
       self.consolidator.Update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
  for tick in ticks:
      self.consolidator.Update(tick)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

  ```
  self.consolidator = self.Consolidate(self.symbol, timedelta(milliseconds=100),
  self.consolidation_handler)
  ```

- `Resolution` Periods

  ```
  self.consolidator = self.Consolidate(self.symbol, Resolution.Second, self.consolidation_handler)
  ```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `timedelta` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `timedelta` Periods

     ```
     self.consolidator = TickQuoteBarConsolidator(timedelta(milliseconds=100))
     # Aliases:
     # self.consolidator = self.CreateConsolidator(timedelta(milliseconds=100), Tick, TickType.Quote)
     # self.consolidator = self.ResolveConsolidator(self.symbol, timedelta(milliseconds=100))
     ```

     The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

- `Resolution` Periods

  The `Resolution` enumeration has the following members:

  ```
  self.consolidator = self.ResolveConsolidator(self.symbol, Resolution.Second)
  ```

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone . If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars milliseconds after 9:30 AM Eastern Time (ET). The consolidated bar for US Equities doesn't close at 4:00 PM ET because the day isn't over. The consolidated bar for US Equities also doesn't close at midnight because your algorithm doesn't receive minute resolution data after 4:00 PM ET until milliseconds after 9:30 AM ET.

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

```
self.consolidator = self.Consolidate(self.symbol, timedelta(milliseconds=100), TickType.Quote,
self.consolidation_handler)
```

- `Resolution` Periods

```
self.consolidator = self.Consolidate(self.symbol, Resolution.Second, TickType.Quote,
self.consolidation_handler)
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: QuoteBar) -> None:
    pass
```

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow

these steps to create and manage a <dataType> consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a timedelta or Resolution object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

- timedelta Periods

```
PY
self.consolidator = DynamicDataConsolidator(timedelta(days=1))
# Aliases:
# self.consolidator = self.CreateConsolidator(timedelta(days=1), <dataType>)
# self.consolidator = self.ResolveConsolidator(self.symbol, timedelta(days=1))
```

  The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

- Resolution Periods

  The Resolution enumeration has the following members:

```
PY
self.consolidator = self.ResolveConsolidator(self.symbol, Resolution.Daily)
```

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

- Add an event handler to the consolidator.

```
PY
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis () at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be self.consolidation_handler , not self.consolidation_handler() .

- Define the consolidation handler.

```
PY
def consolidation_handler(self, sender: object, consolidated_bar: <dataType>) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone .

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the data subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  PY
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  PY
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      if self.symbol in slice:
          self.consolidator.Update(slice[self.symbol])

  # Example 2: Update the consolidator with data from a history request
  history = self.History[<dataType>](self.symbol, 30, Resolution.Daily)
  for data in history:
      self.consolidator.Update(data)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
PY
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `timedelta` or `Resolution` object:

- `timedelta` Periods

  ```
  PY
  self.consolidator = self.Consolidate(self.symbol, timedelta(days=1), self.consolidation_handler)
  ```

- `Resolution` Periods

  ```
  PY
  self.consolidator = self.Consolidate(self.symbol, Resolution.Daily, self.consolidation_handler)
  ```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: <dataType>) -> None:
    pass
```

Consolidator Types

Calendar Consolidators

Introduction

Calendar consolidators aggregate data based on specific periods of time like a weekly basis, quarterly basis, or any schedule with specific start and end times. In contrast to time period consolidators, the bars that calendar consolidators produce always end on the same schedule, regardless of the first data point the consolidator receives.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

- Standard Periods

  The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

```
self.consolidator = TradeBarConsolidator(Calendar.Weekly)
# Alias:
# self.consolidator = self.CreateConsolidator(Calendar.Weekly, TradeBar)
```

PY

- Custom Periods

  If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the

duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
# Define a consolidation period method
def consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self.consolidator = TradeBarConsolidator(self.consolidation_period)
```

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
PY
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    trade_bar = slice.Bars[self.symbol]
    self.consolidator.Update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[TradeBar](self.symbol, 30, Resolution.Minute)
for trade_bar in history:
    self.consolidator.Update(trade_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
PY
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
PY
self.consolidator = self.Consolidate(self.symbol, Calendar.Weekly, self.consolidation_handler)
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
PY
def consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

- Standard Periods

  The following table describes the helper methods that the `Calendar` class provides to create the built-in

`CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

```
PY
self.consolidator = QuoteBarConsolidator(Calendar.Weekly)
# Alias:
# self.consolidator = self.CreateConsolidator(Calendar.Weekly, QuoteBar)
```

- Custom Periods

  If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
PY
# Define a consolidation period method
def consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self.consolidator = QuoteBarConsolidator(self.consolidation_period)
```

- Add an event handler to the consolidator.

```
PY
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be

`self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
PY
def consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  PY
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  PY
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      quote_bar = slice.QuoteBars[self.symbol]
      self.consolidator.Update(quote_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.History[QuoteBar](self.symbol, 30, Resolution.Minute)
  for quote_bar in history:
      self.consolidator.Update(quote_bar)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
PY
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self.consolidator = self.Consolidate(self.symbol, Calendar.Weekly, TickType.Quote,
self.consolidation_handler)
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: QuoteBar) -> None:
    pass
```

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

- Standard Periods

  The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

```
self.consolidator = TickConsolidator(Calendar.Weekly)
# Alias:
# self.consolidator = self.CreateConsolidator(Calendar.Weekly, Tick)
```

- Custom Periods

  If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the

duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
# Define a consolidation period method
def consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self.consolidator = TickConsolidator(self.consolidation_period)
```

PY

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

PY

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

PY

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

  PY

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self.consolidator = self.Consolidate(self.symbol, Calendar.Weekly, self.consolidation_handler)
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: TradeBar) -> None:
    pass
```

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

- Standard Periods

  The following table describes the helper methods that the `Calendar` class provides to create the built-in

`CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

```
PY
self.consolidator = TickQuoteBarConsolidator(Calendar.Weekly)
# Alias:
# self.consolidator = self.CreateConsolidator(Calendar.Weekly, Tick, TickType.Quote)
```

- Custom Periods

  If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
PY
# Define a consolidation period method
def consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self.consolidator = TickQuoteBarConsolidator(self.consolidation_period)
```

- Add an event handler to the consolidator.

```
PY
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be

`self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      ticks = slice.Ticks[self.symbol]
      for tick in ticks:
       self.consolidator.Update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
  for tick in ticks:
      self.consolidator.Update(tick)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self.consolidator = self.Consolidate(self.symbol, Calendar.Weekly, TickType.Quote,
self.consolidation_handler)
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: QuoteBar) -> None:
    pass
```

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

- Standard Periods

  The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

```
self.consolidator = DynamicDataConsolidator(Calendar.Weekly)
# Alias:
# self.consolidator = self.CreateConsolidator(Calendar.Weekly, <dataType>)
```

- Custom Periods

  If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `datetime` object that's based in the data time zone

and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
PY
# Define a consolidation period method
def consolidation_period(self, dt: datetime) -> CalendarInfo:
    period = timedelta(7)

    dt = dt.replace(hour=17, minute=0, second=0, microsecond=0)
    delta = 1+dt.weekday()
    if delta > 6:
        delta = 0
    start = dt-timedelta(delta)

    return CalendarInfo(start, period)

# Create the consolidator with the consolidation period method
self.consolidator = DynamicDataConsolidator(self.consolidation_period)
```

- Add an event handler to the consolidator.

```
PY
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
PY
def consolidation_handler(self, sender: object, consolidated_bar: <dataType>) -> None:
    pass
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the data subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  PY
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      if self.symbol in slice:
          self.consolidator.Update(slice[self.symbol])

  # Example 2: Update the consolidator with data from a history request
  history = self.History[<dataType>](self.symbol, 30, Resolution.Daily)
  for data in history:
      self.consolidator.Update(data)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
self.consolidator = self.Consolidate(self.symbol, Calendar.Weekly, self.consolidation_handler)
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
def consolidation_handler(self, consolidated_bar: <dataType>) -> None:
    pass
```

Examples

The following examples are typical calendar functions you may want.

The function should receive a `datetime` object that's based in the algorithm time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. This function is evaluated when the duration of the consolidation period has passed and at the following time step.

The preceding sections of this page provide a typical calendar function that consolidates data weekly, starting at 5:00 PM. If you consolidate US Equity and Crypto data, the event handler triggers at different times since the data time zone

of US Equity is America/New York and Crypto is UTC.

Example 1: Consolidate data into 20-minute `TradeBar` objects that start at 9:30 AM

This is a typical case for the US markets because they open every business day at 9:30 PM Eastern Time (ET).

```py
def every_twenty_minute_after_equity_market_open(self, dt: datetime) -> CalendarInfo:
    period = timedelta(minutes=20)
    open_time = dt.replace(hour=9, minute=30, second=0, microsecond=0)
    start = open_time + int((dt - open_time) / period) * period
    return CalendarInfo(start, period)
```

To consolidate data into another period, change the `period` variable. For example, to consolidate into 4-hour bars, replace `timedelta(minutes=20)` with `timedelta(hours=4)`

Example 2: Consolidate data in daily `QuoteBar` objects that start at 5 PM:

This is a typical Forex case because the Forex market opens on Sunday at 5 PM ET.

```py
def custom_daily_forex(self, dt: datetime) -> CalendarInfo:
start = dt.replace(hour=17, minute=0, second=0)
if dt.hour < 17:
    start -= timedelta(1)
return CalendarInfo(start, timedelta(1))
```

Example 3: Consolidate data into monthly `TradeBar` objects that start at midnight:

```py
def custom_monthly(self, dt: datetime) -> CalendarInfo:
    start = dt.replace(day=1).date()
    end = dt.replace(day=28) + timedelta(4)
    end = (end - timedelta(end.day - 1)).date()
    return CalendarInfo(start, end - start)
```

Demonstration Algorithms
DataConsolidationAlgorithm.py Python

Consolidator Types

Count Consolidators

Introduction

Count consolidators aggregate data based on a number of bars or ticks. This type of consolidator aggregates **n** samples together, regardless of the time period the samples cover. Managing count consolidators is similiar to managing time period consolidators , except you create count consolidators with an integer argument instead of a time-based argument.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   self.consolidator = TradeBarConsolidator(10)
   ```

2. Add an event handler to the consolidator.

   ```
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
       pass
   ```

   When the consolidator receives the **n** -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    trade_bar = slice.Bars[self.symbol]
    self.consolidator.Update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[TradeBar](self.symbol, 30, Resolution.Minute)
for trade_bar in history:
    self.consolidator.Update(trade_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

```
self.consolidator = QuoteBarConsolidator(10)
```

2. Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
PY
def consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

When the consolidator receives the **n** -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
PY
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
PY
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    quote_bar = slice.QuoteBars[self.symbol]
    self.consolidator.Update(quote_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[QuoteBar](self.symbol, 30, Resolution.Minute)
for quote_bar in history:
    self.consolidator.Update(quote_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
PY
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to

slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   self.consolidator = TickConsolidator(10)
   ```
   PY

2. Add an event handler to the consolidator.

   ```
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```
   PY

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
       pass
   ```
   PY

   When the consolidator receives the **n** -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```
  PY

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To

manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   self.consolidator = TickQuoteBarConsolidator(10)
   ```

2. Add an event handler to the consolidator.

   ```
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

When the consolidator receives the **n** -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   self.consolidator = DynamicDataConsolidator(10)
   ```
   PY

2. Add an event handler to the consolidator.

   ```
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```
   PY

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def consolidation_handler(self, sender: object, consolidated_bar: <dataType>) -> None:
       pass
   ```
   PY

   When the consolidator receives the **n** -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the data subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```
  PY

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice:
        self.consolidator.Update(slice[self.symbol])

# Example 2: Update the consolidator with data from a history request
history = self.History[<dataType>](self.symbol, 30, Resolution.Daily)
for data in history:
    self.consolidator.Update(data)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidator Types

Mixed-Mode Consolidators

Introduction

Mixed-mode consolidators are a combination of count consolidators and time period consolidators. This type of consolidator aggregates **n** samples together or aggregates samples over a specific time period, whichever happens first.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   self.consolidator = TradeBarConsolidator(10, timedelta(days=1))
   ```

   The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

2. Add an event handler to the consolidator.

   ```
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first. If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at 9:31 AM Eastern Time (ET). The consolidated bar for US Equities doesn't close at 4:00 PM ET because the day isn't over. The consolidated bar for US Equities also doesn't close at midnight because your algorithm doesn't receive minute resolution data after 4:00 PM ET until 9:31 AM ET.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    trade_bar = slice.Bars[self.symbol]
    self.consolidator.Update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[TradeBar](self.symbol, 30, Resolution.Minute)
for trade_bar in history:
    self.consolidator.Update(trade_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe

subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   self.consolidator = QuoteBarConsolidator(10, timedelta(days=1))
   ```

   The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

2. Add an event handler to the consolidator.

   ```
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first. If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at 9:31 AM Eastern Time (ET). The consolidated bar for US Equities doesn't close at 4:00 PM ET because the day isn't over. The consolidated bar for US Equities also doesn't close at midnight because your

algorithm doesn't receive minute resolution data after 4:00 PM ET until 9:31 AM ET.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    quote_bar = slice.QuoteBars[self.symbol]
    self.consolidator.Update(quote_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[QuoteBar](self.symbol, 30, Resolution.Minute)
for quote_bar in history:
    self.consolidator.Update(quote_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute

bars.

```
self.consolidator = TickConsolidator(10, timedelta(milliseconds=100))
```

The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

2. Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first. If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars milliseconds after 9:30 AM Eastern Time (ET). The consolidated bar for US Equities doesn't close at 4:00 PM ET because the day isn't over. The consolidated bar for US Equities also doesn't close at midnight because your algorithm doesn't receive minute resolution data after 4:00 PM ET until milliseconds after 9:30 AM ET.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

```
self.consolidator = TickQuoteBarConsolidator(10, timedelta(milliseconds=100))
```

   The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time

(UTC), regardless of the algorithm time zone.

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

2. Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: QuoteBar) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first. If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars milliseconds after 9:30 AM Eastern Time (ET). The consolidated bar for US Equities doesn't close at 4:00 PM ET because the day isn't over. The consolidated bar for US Equities also doesn't close at midnight because your algorithm doesn't receive minute resolution data after 4:00 PM ET until milliseconds after 9:30 AM ET.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with

data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `timedelta` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   self.consolidator = DynamicDataConsolidator(10, timedelta(days=1))
   ```

   The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET.

2. Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: <dataType>) -> None:
    pass
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the data subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice:
        self.consolidator.Update(slice[self.symbol])

# Example 2: Update the consolidator with data from a history request
history = self.History[<dataType>](self.symbol, 30, Resolution.Daily)
for data in history:
    self.consolidator.Update(data)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidator Types

Renko Consolidators

Renko Consolidators

Renko Consolidators

Introduction

Most Renko consolidators aggregate bars based on a fixed price movement. The `RenkoConsolidator` produces Renko bars by their traditional definition. In the case of a $1 bar size, the `RenkoConsolidator` produces bars that have a body spanning 1.*Theopeningpriceofthefirstbarissettotheclosest*1 multiple of the first trade. When the price moves by at least 1, *thefirstbarcloses*. *Ifabarisarisingbar*, *thefollowingbarcloseswhenthepricemoves*1 above the closing price of the previous bar or 1*belowtheopeningpriceofthepreviousbar*. *Ifabarisafallingbar*, *thefollowingbarcloseswhenthepricemoves*1 below the closing price of the previous bar or $1 above the opening price of the previous bar. If the price jumps multiple dollars in a single tick, the `RenkoConsolidator` produces multiple $1 bars in a single time step.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   # Create a Renko consolidator that emits a bar when the price moves $1
   self.consolidator = RenkoConsolidator(1)
   ```

2. Add an event handler to the consolidator.

   ```
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    trade_bar = slice.Bars[self.symbol]
    self.consolidator.Update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[TradeBar](self.symbol, 30, Resolution.Minute)
for trade_bar in history:
    self.consolidator.Update(trade_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

```
# Create a Renko consolidator that emits a bar when the price moves $1
self.consolidator = RenkoConsolidator(1)
```

2. Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    quote_bar = slice.QuoteBars[self.symbol]
    self.consolidator.Update(quote_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[QuoteBar](self.symbol, 30, Resolution.Minute)
for quote_bar in history:
    self.consolidator.Update(quote_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   # Create a Renko consolidator that emits a bar when the price moves $1
   self.consolidator = RenkoConsolidator(1)
   ```

2. Add an event handler to the consolidator.

   ```
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

   ```
   def consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
       pass
   ```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RenkoBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

```
# Create a Renko consolidator that emits a bar when the price moves $1
self.consolidator = RenkoConsolidator(1)
```

2. Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Renko Consolidators

Classic Renko Consolidators

Introduction

Most Renko consolidators aggregate bars based on a fixed price movement. The `ClassicRenkoConsolidator` produces a different type of Renko bars than the `RenkoConsolidator` . A `ClassicRenkoConsolidator` with a bar size of 1*producesanewbarthatspans*1 every time an asset closes $1 away from the close of the previous bar. If the price jumps multiple dollars in a single tick, the `ClassicRenkoConsolidator` only produces one bar per time step where the open of each bar matches the close of the previous bar.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   # Create a Classic Renko consolidator that emits a bar when the price moves $1
   self.consolidator = ClassicRenkoConsolidator(1)
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

- It uses the `Value` property of the `IBaseData` object it receives to build the Renko bars
- It ignores the volume of the input data
- It enforces the open and close of each bar to be a multiple of the bar size

To build the Renko bars with a different property than the `Value` of the `IBaseData` object, provide a `selector` argument. The `selector` should be a function that receives the `IBaseData` object and returns a decimal value.

```
self.consolidator = ClassicRenkoConsolidator(1, selector = lambda data: data.High)
```

To add a non-zero `Volume` property to the Renko bars, provide a `volumeSelector` argument. The `volumeSelector` should be a function that receives the `IBaseData` object and returns a decimal value.

```
self.consolidator = ClassicRenkoConsolidator(1, volumeSelector = lambda data: data.Volume)
```

To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `evenBars` argument. If you disable `evenBars` , the open value of the first Renko bar is set to the first value from the `selector` .

The following opening and closing Renko bar values are all multiples of the first value from the `selector`

```
self.consolidator = ClassicRenkoConsolidator(1, evenBars = False)
```

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    trade_bar = slice.Bars[self.symbol]
    self.consolidator.Update(trade_bar)

# Example 2: Update the consolidator with data from a history request
history = self.History[TradeBar](self.symbol, 30, Resolution.Minute)
for trade_bar in history:
    self.consolidator.Update(trade_bar)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   # Create a Classic Renko consolidator that emits a bar when the price moves $1
   self.consolidator = ClassicRenkoConsolidator(1)
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

- It uses the `Value` property of the `IBaseData` object it receives to build the Renko bars
- It ignores the volume of the input data
- It enforces the open and close of each bar to be a multiple of the bar size

The following arguments enable you to create Renko bars that aggregate the excess liquidity on the bid.

```
self.consolidator = ClassicRenkoConsolidator(10, lambda data: data.Value, lambda data: data.LastBidSize - data.LastAskSize)
```

To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `evenBars` argument. If you disable `evenBars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

```
self.consolidator = ClassicRenkoConsolidator(1, evenBars = False)
```

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      quote_bar = slice.QuoteBars[self.symbol]
      self.consolidator.Update(quote_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.History[QuoteBar](self.symbol, 30, Resolution.Minute)
  for quote_bar in history:
      self.consolidator.Update(quote_bar)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   # Create a Classic Renko consolidator that emits a bar when the price moves $1
   self.consolidator = ClassicRenkoConsolidator(1)
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

- It uses the `Value` property of the `IBaseData` object it receives to build the Renko bars
- It ignores the volume of the input data
- It enforces the open and close of each bar to be a multiple of the bar size

To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `evenBars` argument. If you disable `evenBars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

```
self.consolidator = ClassicRenkoConsolidator(1, evenBars = False)
```

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      ticks = slice.Ticks[self.symbol]
      for tick in ticks:
       self.consolidator.Update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
  for tick in ticks:
      self.consolidator.Update(tick)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RenkoBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   # Create a Classic Renko consolidator that emits a bar when the price moves $1
   self.consolidator = ClassicRenkoConsolidator(1)
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

- It uses the `Value` property of the `IBaseData` object it receives to build the Renko bars
- It ignores the volume of the input data
- It enforces the open and close of each bar to be a multiple of the bar size

To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `evenBars` argument. If you disable `evenBars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

```
self.consolidator = ClassicRenkoConsolidator(1, evenBars = False)
```

- Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

- Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: RenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

- Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      ticks = slice.Ticks[self.symbol]
      for tick in ticks:
       self.consolidator.Update(tick)

  # Example 2: Update the consolidator with data from a history request
  ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
  for tick in ticks:
      self.consolidator.Update(tick)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Renko Consolidators

Volume Renko Consolidators

Introduction

Volume Renko consolidators aggregate bars based on a fixed trading volume. These types of bars are commonly known as volume bars. A `VolumeRenkoConsolidator` with a bar size of 10,000 produces a new bar every time 10,000 units of the security trades in the market. If the trading volume of a single time step exceeds two step sizes (i.e. >20,000), the `VolumeRenkoConsolidator` produces multiple bars in a single time step.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `VolumeRenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on custom set volume traded:

1. Create the consolidator.

   To create a Volume Renko consolidator, pass the bar size to the `VolumeRenkoConsolidator` constructor.

   ```
   PY
   # Create a Volume Renko consolidator that emits a bar every time 10,000 units trade
   self.consolidator = VolumeRenkoConsolidator(10000)
   ```

2. Add an event handler to the consolidator.

   ```
   PY
   self.consolidator.DataConsolidated += self.consolidation_handler
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

   ```
   PY
   def consolidation_handler(self, sender: object, consolidated_bar: VolumeRenkoBar) -> None:
       pass
   ```

   The consolidation event handler receives bars when the trading volume forms a new Volume Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  PY
  self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  PY
  # Example 1: Update the consolidator with data from the Slice object
  def OnData(self, slice: Slice) -> None:
      trade_bar = slice.Bars[self.symbol]
      self.consolidator.Update(trade_bar)

  # Example 2: Update the consolidator with data from a history request
  history = self.History[TradeBar](self.symbol, 30, Resolution.Minute)
  for trade_bar in history:
      self.consolidator.Update(trade_bar)
  ```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
PY
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `VolumeRenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on custom set volume traded:

1. Create the consolidator.

   To create a Volume Renko consolidator, pass the bar size to the `VolumeRenkoConsolidator` constructor.

   ```
   PY
   # Create a Volume Renko consolidator that emits a bar every time 10,000 units trade
   self.consolidator = VolumeRenkoConsolidator(10000)
   ```

2. Add an event handler to the consolidator.

```
self.consolidator.DataConsolidated += self.consolidation_handler
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `self.consolidation_handler` , not `self.consolidation_handler()` .

3. Define the consolidation handler.

```
def consolidation_handler(self, sender: object, consolidated_bar: VolumeRenkoBar) -> None:
    pass
```

The consolidation event handler receives bars when the trading volume forms a new Volume Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
# Example 1: Update the consolidator with data from the Slice object
def OnData(self, slice: Slice) -> None:
    ticks = slice.Ticks[self.symbol]
    for tick in ticks:
     self.consolidator.Update(tick)

# Example 2: Update the consolidator with data from a history request
ticks = self.History[Tick](self.symbol, timedelta(minutes=3), Resolution.Tick)
for tick in ticks:
    self.consolidator.Update(tick)
```

- If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
self.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidator Types

Combining Consolidators

Introduction

Sequential consolidators wire two internal consolidators together such that the output of the first consolidator is the input to the second consolidator and the output of the second consolidator is the output of the sequential consolidator.

Create Consolidators

To create a sequential consolidator, create two consolidators and then pass them to the `SequentialConsolidator` constructor.

```
# This first consolidator produces a consolidated bar after a day passes
one_day_consolidator = TradeBarConsolidator(timedelta(days=1))

# This second consolidators produces a consolidated bar after it sees 3 samples
three_count_consolidator = TradeBarConsolidator(3)

# This sequential consolidator aggregates three 1-day bars together
self.consolidator = SequentialConsolidator(one_day_consolidator, three_count_consolidator)
```

PY

For more information about each type of consolidator, see Consolidator Types .

DataConsolidationAlgorithm.py Python

Consolidating Data

Consolidator History

Introduction

This page explains how to save and access historical consolidated bars.

Save Consolidated Bars

To access historical bars that were passed to your consolidation handler, save the bars as you receive them. You can use a RollingWindow to save the consolidated bars and easily access them later on in your algorithm.

```
PY

# Create a class member to store the RollingWindow
self.window = RollingWindow[TradeBar](2)

# In the consolidation handler, add consolidated bars to the RollingWindow
def consolidation_handler(self, sender: object, consolidated_bar: TradeBar) -> None:
    self.window.Add(consolidated_bar)
```

Get Historical Bars

If you save consolidated bars in a `RollingWindow` , you can access them by indexing the `RollingWindow` . `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window.

```
PY

most_recent_bar = self.window[0]
previous_bar = self.window[1]
oldest_bar = self.window[self.window.Count-1]
```

To get the consolidated bar that was most recently removed from the `RollingWindow` , use the `MostRecentlyRemoved` property.

```
PY

removed_bar = self.window.MostRecentlyRemoved
```

Consolidating Data

Updating Indicators

Introduction

You can use consolidators to automatically update indicators in your algorithms. The consolidators can update your indicators at each time step or with aggregated bars. By default, LEAN updates data point indicators with the close price of the consolidated bars, but you can change it to a custom data field.

Standard Indicator Periods

If your algorithm has a static universe, you can create automatic indicators in just one line of code. When you create an automatic indicator, LEAN creates a consolidator, hooks it up for automatic updates, and then updates the indicator with the consolidated bars.

```
PY
 # Consolidate minute SPY data into 14-bar daily indicators
ema = self.EMA("SPY", 14, Resolution.Daily)
sma = self.SMA("SPY", 14, Resolution.Daily)
```

If your algorithm has a dynamic universe, create a manual indicator and then create a time period consolidator that updates the indicator at each time step. Keep a reference to the consolidator so you can remove it when your algorithm removes the security from the universe.

```
PY
self.ema = ExponentialMovingAverage(14)
self.consolidator = TradeBarConsolidator(1)
self.consolidator.DataConsolidated += lambda _, bar: self.ema.Update(bar.EndTime, bar.Close)
self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)
```

Custom Indicator Periods

It's common to update indicators with price data that spans a normal time period like one minute or one day. It's less common to update an indicator with exotic time periods (for example, a 7-minute consolidated bar), so these types of indicators may provide more opportunities for alpha. To update indicators with exotic data, create a manual indicator and then call the `RegisterIndicator` method. The `RegisterIndicator` method wires up the indicator for automatic updates at the time interval you provide.

```
PY
# Calculate the SMA with 10 7-minute bars
self.symbol = self.AddEquity("SPY", Resolution.Minute).Symbol
self.indicator = SimpleMovingAverage(10)
self.RegisterIndicator(self.symbol, self.indicator, timedelta(minutes=7))
```

The `RegisterIndicator` method can accept a `timedelta` , `Resolution` , or an unregistered consolidator. If you apply the indicator to a security in a dynamic universe, provide a consolidator so that you can remove it when your algorithm

removes the security from the universe.

```py
# timedelta
self.RegisterIndicator(self.symbol, self.indicator, timedelta(minutes=7))

# Resolution
self.RegisterIndicator(self.symbol, self.indicator, Resolution.Hour)

# Consolidator
self.consolidator = TradeBarConsolidator(35)
self.RegisterIndicator(self.symbol, self.indicator, self.consolidator)
```

Custom Indicator Values

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with `TradeBar` data, that price is the `TradeBar` close price. For assets with `QuoteBar` data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the `Open` , `High` , `Low` , or `Close` , provide a `selector` argument to the `RegisterIndicator` method.

```py
# Define a 10-period RSI with indicator constructor
self.rsi = RelativeStrengthIndex(10, MovingAverageType.Simple)

# Register the daily High price data to automatically update the indicator
self.RegisterIndicator(self.symbol, self.rsi, Resolution.Daily, Field.High)
```

The `RegisterIndicator` method can accept a `timedelta` , `Resolution` , or an unregistered consolidator. If you apply the indicator to a security in a dynamic universe, provide a consolidator so that you can remove it when your algorithm removes the security from the universe.

The `Field` class has the following `selector` properties:

Historical Data

Historical Data

History Requests

Introduction

There are two ways to request historical data in your algorithms: direct historical data requests and indirect algorithm warm up . You can use a direct historical data request at any time throughout your algorithm. It returns all of the data you request as a single object.

Key History Concepts

The historical data API has many different options to give you the greatest flexibility in how to apply it to your algorithm.

Time Period Options

You can request historical data based on a trailing number of bars, a trailing period of time, or a defined period of time. If you request data in a defined period of time, the `datetime` objects you provide are based in the algorithm time zone .

Return Formats

Each asset class supports slightly different data formats. When you make a history request, consider what data returns. Depending on how you request the data, history requests return a specific data type. For example, if you don't provide `Symbol` objects, you get `Slice` objects that contain the entire universe.

The most popular return type is a `DataFrame` . If you request a `DataFrame` , LEAN unpacks the data from `Slice` objects to populate the `DataFrame` . If you intend to use the data in the `DataFrame` to create `TradeBar` or `QuoteBar` objects, request that the history request returns the data type you need. Otherwise, LEAN will waste computational resources populating the `DataFrame` .

Time Index

When your history request returns a `DataFrame` , the timestamps in the `DataFrame` are based on the data time zone . When your history request returns a `TradeBars` , `QuoteBars` , `Ticks` , or `Slice` object, the `Time` properties of these objects are based on the algorithm time zone, but the `EndTime` properties of the individual `TradeBar` , `QuoteBar` , and `Tick` objects are based on the data time zone . The `EndTime` is the end of the sampling period and when the data is actually available. For daily US Equity data, this results in data points appearing on Saturday and skipping Monday.

Request Data

The simplest form of history request is for a known set of `Symbol` objects. This is common for fixed universes of

securities or when you need to prepare new securities added to your algorithm. History requests return slightly different data depending on the overload you call. The data that returns is in ascending order from oldest to newest. This order is necessary to use the data to warm up indicators.

Single Symbol History Requests

To request history for a single asset, pass the asset `Symbol` to the `History` method. The return type of the method call depends on the history request `[Type]` . The following table describes the return type of each request `[Type]` :

Request Type	Return Data Type
No argument	`DataFrame`
`TradeBar`	`List[TradeBars]`
`QuoteBar`	`List[QuoteBars]`
`Tick`	`List[Ticks]`
`alternativeDataClass` (ex: `CBOE`)	`List[ alternativeDataClass ]` (ex: `List[CBOE]`)

Each row of the DataFrame represents the prices at a point in time. Each column of the DataFrame is a property of that price data (for example, open, high, low, and close (OHLC)). If you request a DataFrame object and pass `TradeBar` as the first argument, the DataFrame that returns only contains the OHLC and volume columns. If you request a DataFrame object and pass `QuoteBar` as the first argument, the DataFrame that returns contains the OHLC of the bid and ask and it contains OHLC columns, which are the respective means of the bid and ask OHLC values. If you request a DataFrame and don't pass `TradeBar` or `QuoteBar` as the first arugment, the DataFrame that returns contains columns for all of the data that's available for the given resolution.

PY

```
# EXAMPLE 1: Requesting By Bar Count: 5 bars at the security resolution:
vix_symbol = self.AddData(CBOE, "VIX", Resolution.Daily).Symbol
cboe_data = self.History[CBOE](vix_symbol, 5)

btc_symbol = self.AddCrypto("BTCUSD", Resolution.Minute).Symbol
trade_bars = self.History[TradeBar](btc_symbol, 5)
quote_bars = self.History[QuoteBar](btc_symbol, 5)
trade_bars_df = self.History(TradeBar, btc_symbol, 5)
quote_bars_df = self.History(QuoteBar, btc_symbol, 5)
df = self.History(btc_symbol, 5)   # Includes trade and quote data

Multiple Symbol History Requests

To request history for multiple symbols at a time, pass an array of `Symbol` objects to the same API methods shown in the preceding section. The return type of the method call depends on the history request `[Type]` . The following table describes the return type of each request `[Type]` :

Request Type	Return Data Type
No argument	`DataFrame`
`TradeBar`	`List[TradeBars]`
`QuoteBar`	`List[QuoteBars]`
`Tick`	`List[Ticks]`
`alternativeDataClass` (ex: `CBOE`)	`List[Dict[Symbol, alternativeDataClass ]]` (ex: `List[Dict[Symbol, CBOE]]`)

PY

```
# EXAMPLE 7: Requesting By Bar Count for Multiple Symbols: 2 bars at the security resolution:
vix = self.AddData[CBOE]("VIX", Resolution.Daily).Symbol
v3m = self.AddData[CBOE]("VIX3M", Resolution.Daily).Symbol
cboe_data = self.History[CBOE]([vix, v3m], 2)

ibm = self.AddEquity("IBM", Resolution.Minute).Symbol
aapl = self.AddEquity("AAPL", Resolution.Minute).Symbol
trade_bars_list = self.History[TradeBar]([ibm, aapl], 2)
quote_bars_list = self.History[QuoteBar]([ibm, aapl], 2)

trade_bars_df = self.History(TradeBar, [ibm, aapl], 2)
quote_bars_df = self.History(QuoteBar, [ibm, aapl], 2)
df = self.History([ibm, aapl], 2)  # Includes trade and quote data

If you request data for multiple securities and you use the `Tick` request type, each `Ticks` object in the list of results only contains the last tick of each security for that particular timeslice .

All Symbol History Requests

You can request history for all active securities in your universe. The parameters are very similar to other history method calls, but the return type is an array of Slice objects. The `Slice` object holds all of the results in a sorted enumerable collection that you can iterate over with a loop.

PY

```
# EXAMPLE 11: Requesting 5 bars for all securities at their respective resolution:

# Create subscriptions
self.AddEquity("IBM", Resolution.Daily)
self.AddEquity("AAPL", Resolution.Daily)

# Request history data and enumerate results
slices = self.History(5)
for s in slices:
    self.Log(str(s.Time) + " AAPL:" + str(s.Bars["AAPL"].Close) + " IBM:" + str(s.Bars["IBM"].Close))
```

```
2022-07-02 00:00:00 AAPL:138.93 IBM:141.12
2022-07-06 00:00:00 AAPL:141.56 IBM:137.62
2022-07-07 00:00:00 AAPL:142.92 IBM:138.08
2022-07-08 00:00:00 AAPL:146.35 IBM:140.83
2022-07-09 00:00:00 AAPL:147.04 IBM:140.47
```

PY

```
# EXAMPLE 12: Requesting 5 minutes for all securities:

slices = self.History(timedelta(minutes=5), Resolution.Minute)
for s in slices:
    self.Log(str(s.Time) + " AAPL:" + str(s.Bars["AAPL"].Close) + " IBM:" + str(s.Bars["IBM"].Close))
```

```
2022-07-08 15:56:00 AAPL:147.2 IBM:140.71
2022-07-08 15:57:00 AAPL:147.125 IBM:140.67
2022-07-08 15:58:00 AAPL:147.065 IBM:140.61
2022-07-08 15:59:00 AAPL:147.02 IBM:140.49
2022-07-08 16:00:00 AAPL:147.04 IBM:140.47
```

```
# timedelta history requests are relative to "now" in algorithm Time. If you request this data at 16:05,
it returns an empty array because the market is closed.
```

Assumed Default Values

The following table describes the assumptions of the History API:

Argument	Assumption
Resolution	LEAN guesses the resolution you request by looking at the securities you already have in your algorithm. If you have a security subscription in your algorithm with a matching `Symbol` , the history request uses the same resolution as the subscription. If you don't have a security subscription in your algorithm with a matching `Symbol` , `Resolution.Minute` is the default.

Additional Options

The `History` method accepts the following additional arguments:

Argument	Data Type	Description	Default Value
`fillForward`	`bool/NoneType`	True to fill forward missing data. Otherwise, false.	`None`
`extendedMarketHours`	`bool/NoneType`	True to include extended market hours data. Otherwise, false.	`None`
`dataMappingMode`	`DataMappingMode/NoneType`	The contract mapping mode to use for the security history request.	`None`
`dataNormalizationMode`	`DataNormalizationMode/NoneType`	The price scaling mode to use for US Equities or continuous Futures contracts . If you don't provide a value, it uses the data normalization mode of the security subscription.	`None`
`contractDepthOffset`	`int/NoneType`	The desired offset from the current front month for continuous Futures contracts .	`None`

```py
self.future = self.AddFuture(Futures.Currencies.BTC)
history = self.History(
    tickers=[self.future.Symbol],
    start=self.Time - timedelta(days=15),
    end=self.Time,
    resolution=Resolution.Minute,
    fillForward=False,
    extendedMarketHours=False,
    dataMappingMode=DataMappingMode.OpenInterest,
    dataNormalizationMode=DataNormalizationMode.Raw,
    contractDepthOffset=0)
```

Analyze Results

The History method returns a multi-index DataFrame where the first index is the `Symbol` . The data is then sorted in rows according to the second index, the EndTime of the bar. By learning a few helpful shortcuts, you can directly access the history values you need for your algorithm.

PY

```
# Setup the universe:
eurusd = self.AddForex("EURUSD", Resolution.Daily).Symbol
nzdusd = self.AddForex("NZDUSD", Resolution.Daily).Symbol

# STEP 1:  Request a DataFrame:
self.df = self.History([eurusd, nzdusd], 3)

Data Formats

We provide a specific data formats for each asset class. To view the available data formats, see the **Resolutions** documentation of the following asset classes:

- US Equity
- India Equity
- Equity Options
- Crypto
- Crypto Futures
- Forex
- Futures
- Future Options
- Index
- Index Options
- CFD

Common Errors

Errors can occur when you request historical data.

Empty Data Errors

If the history request returns an empty DataFrame and you try to slice it, it throws an exception. To avoid issues, check if the DataFrame contains data before slicing it.

```
df = self.History(symbol, 10).close    # raises exception if the request is empty

def GetSafeHistoryCloses(self, symbols):
    if not symbols:
        self.Log(f'No symbols')
        return  False, None
    df = self.History(symbols, 100, Resolution.Daily)
    if df.empty:
        self.Log(f'Empy history for {symbols}')
        return  False, None
     return True, df.close.unstack(0)
```

If you run algorithms on your local machine and history requests return no data, check if your **data** directory contains the data you request. To download datasets, see Download .

Numerical Precision Errors

Some factor files have INF split values, which indicate that the stock has so many splits that prices can't be calculated with correct numerical precision. To allow history requests with these symbols, we need to move the starting date forward when reading the data. If there are numerical precision errors in the factor files for a security in your history request, LEAN throws the following error:

"Warning: when performing history requests, the start date will be adjusted if there are numerical precision errors in the factor files."

Live Trading Considerations

In live trading, if you make a history request for minute data at noon and the history period covers the start of the previous day to the present moment, the data from the previous day will be backtest data. The data of the current day will be live data that we collected throughout the morning. If you make this history request in a backtest, you might get slightly different data for the current day because of post-processing from the data vendor.

Historical Data

Warm Up Periods

Introduction

LEAN supports an automated fast-forward system called "Warm Up". It simulates winding back the clock from the time you deploy the algorithm. In a backest, this is the `StartDate` of your algorithm. In live trading, it's the current date. Warm Up is a great way to prepare your algorithm and its indicators for trading.

Set Warm Up Periods

You can set a warm-up period based on a period of time or a number of bars. To set a warm-up, in your algorithm's `Initialize` method, call the `SetWarmUp` method.

```
PY
# Wind time back 7 days from start
self.SetWarmUp(timedelta(7))

# Feed in 100 bars before start date
self.SetWarmUp(100)
```

If you pass a `timedelta` argument, the warm-up period consists of that `timedelta` before the start date and pipes in data that matches the resolution of your data subscriptions.

If you pass just an integer argument, LEAN calculates the start of the warm-up period for each of your security subscriptions by using the number of bars you specify, the resolution of each security, and the trading calendar of each security. After it calculates the start time of the warm-up period for each security, it sets the earliest start time as the start of the algorithm warm-up period. For instance, in the following example, the warm-up period consists of 100 minute resolution bars for SPY and as many second resolution bars for BTCUSD that occur from the start of the SPY warm-up period to the algorithm `StartDate` .

```
PY
self.AddEquity("SPY", Resolution.Minute, fillForward=False)
self.AddCrypto("BTCUSD", Resolution.Second, fillForward=False)
self.SetWarmUp(100)
```

To use a specific resolution of data for the warm-up period, pass a `resolution` argument to the `SetWarmUp` method.

```
PY
# Feed in 100 days of daily data before the start date
self.SetWarmUp(timedelta(days=100), Resolution.Daily)

# Feed in data for 100 trading days before the start date
self.SetWarmUp(100, Resolution.Daily)
```

If you pass a `timedelta` and a resolution, the warm-up period consists of the time period and resolution you set, regardless of the resolution of your data subscriptions.

If you pass an integer and a resolution, the warm-up period consists of the number of bars and resolution you set, regardless of the resolution of your data subscriptions. In this case, LEAN calculates the start of the warm-up period for each of your security subscriptions just like it does when you only pass an integer argument. After it calculates the start time of the warm-up period for each security, it sets the earliest start time as the start of the algorithm warm-up period.

If you pass a resolution argument and you registered indicators or consolidators for automatic updates, the warm-up period resolution must be less than or equal to the lowest resolution of your automatic indicators and consolidators. For instance, in the following example, the indicators use minute resolution data, so you can set the warm-up period to use tick, second, or minute resolution data.

```
PY

self.spy = self.AddEquity("SPY", Resolution.Minute, fillForward=False).Symbol
self.btc = self.AddCrypto("BTCUSD", Resolution.Second, fillForward=False).Symbol

self.spy_sma = self.SMA(self.spy, 10)
self.btc_sma = self.SMA(self.btc, 10, Resolution.Minute)

self.SetWarmUp(100, Resolution.Minute)
```

Warm Up Vs Reality

You may need to distinguish warm-up data from real data. To check if the algorithm is currently in a warm up period, use the `IsWarmingUp` property.

```
PY

# In Initialize
self.emaFast = self.EMA("IBM", 50);
self.emaSlow = self.EMA("IBM", 100);
self.SetWarmup(100);

// In OnData: Don't run if the indicators aren't ready
if self.IsWarmingUp: return
```

Event Handler

The `OnWarmupFinished` event handler executes when the warm up period ends, even if you don't set a warm up period.

```
PY

def OnWarmupFinished(self) -> None:
    pass # Done warming up
```

Limitations

You can't place trades during the warm-up period because they would be operating on fictional fast-forwarded data.

Demonstration Algorithms
WarmupAlgorithm.py Python

Historical Data

Rolling Window

Introduction

A `RollingWindow` is an array of a fixed-size that holds trailing data. It's more efficient to use `RollingWindow` objects to hold periods of data than to make multiple historical data requests . With a `RollingWindow` , you just update the latest data point while a `History` call fetches all of the data over the period you request. `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window.

Supported Types

`RollingWindow` objects can store any native or C# types.

```
PY
self.close_window = RollingWindow[float](4)
self.trade_bar_window = RollingWindow[TradeBar](2)
self.quote_bar_window = RollingWindow[QuoteBar](2)
```

To be notified when `RollingWindow` objects support additional types, subscribe to GitHub Issue #6199 .

Add Data

To add data to a `RollingWindow` , call the `Add` method.

```
PY
self.close_window.Add(data["SPY"].Close)
self.trade_bar_window.Add(data["SPY"])
self.quote_bar_window.Add(data["EURUSD"])
```

Warm Up

To warm up a `RollingWindow` , make a history request and then iterate through the result to add the data to the `RollingWindow` .

```
PY
spy = self.AddEquity("SPY", Resolution.Daily).Symbol
history_trade_bar = self.History[TradeBar](spy, 10, Resolution.Daily)
history_quote_bar = self.History[QuoteBar](spy, 10, Resolution.Minute)

# Warm up the close price and trade bar rolling windows with the previous 10-day trade bar data
close_price_window = RollingWindow[float](10)
trade_bar_window = RollingWindow[TradeBar](10)
for trade_bar in history_trade_bar:
    close_price_window.Add(trade_bar.Close)
    trade_bar_window.Add(trade_bar)

# Warm up the quote bar rolling window with the previous 10-minute quote bar data
quote_bar_window = RollingWindow[QuoteBar](10)
for quote_bar in history_quote_bar:
    quote_bar_window.Add(quote_bar)
```

Check Readiness

To check if a `RollingWindow` is full, use its `IsReady` flag.

```
PY
if not self.close_window.IsReady:
    return
```

Access Data

`RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window.

```
PY
current_close = self.close_window[0]
previous_close = self.close_window[1]
oldest_close = self.close_window[self.close_window.Count-1]
```

To get the item that was most recently removed from the `RollingWindow` , use the `MostRecentlyRemoved` property.

```
PY
removed_close = self.close_window.MostRecentlyRemoved
```

Combine with Indicators

To track historical indicator values, use a `RollingWindow` . Indicators emit an `Updated` event when they update. To create a `RollingWindow` of indicator points, attach an event handler function to the `Updated` member that adds the last value of the indicator to the `RollingWindow` . The value is an `IndicatorDataPoint` object that represents a piece of data at a specific time.

```
PY
def Initialize(self) -> None:
    # Creates an indicator and adds to a RollingWindow when it is updated
    self.sma_window = RollingWindow[IndicatorDataPoint](5)
    self.SMA("SPY", 5).Updated += (lambda sender, updated: self.sma_window.Add(updated))
```

To view how to access individual members in an indicator, see Get Indicator Values .

```
PY
current_sma = self.sma_window[0]
previous_sma = self.sma_window[1]
oldest_sma = self.sma_window[sma_window.Count - 1]
```

Combine with Consolidators

To store a history of consolidated bars , in the consolidation handler, add the consolidated bar to the `RollingWindow` .

```
PY
self.consolidator.DataConsolidated += lambda sender, consolidated_bar:
self.trade_bar_window.Add(consolidated_bar)
```

Cast to Other Types

You can cast a `RollingWindow` to a list or a DataFrame. If you cast it to a list, reverse the list so the most recent element is at the last index of the list. This is the order the elements would be in if you added the elements to the list with the `Add` method. To cast a `RollingWindow` to a DataFrame, the `RollingWindow` must contain `Slice` , `Tick` , `QuoteBar` , or `TradeBar` objects. If the `RollingWindow` contains ticks, the ticks must have unique timestamps.

```
PY

closes = list(self.close_window)[::-1]

tick_df = self.PandasConverter.GetDataFrame[Tick](list(self.tick_window)[::-1])
trade_bar_df = self.PandasConverter.GetDataFrame[TradeBar](list(self.trade_bar_window)[::-1])
quote_bar_df = self.PandasConverter.GetDataFrame[QuoteBar](list(self.quote_bar_window)[::-1])
```

Delete Data

To remove all of the elements from a `RollingWindow` , call the `Reset` method.

```
PY

self.close_window.Reset()
```

MultipleSymbolConsolidationAlgorithm.py Python

Trading and Orders

Trading and Orders

Key Concepts

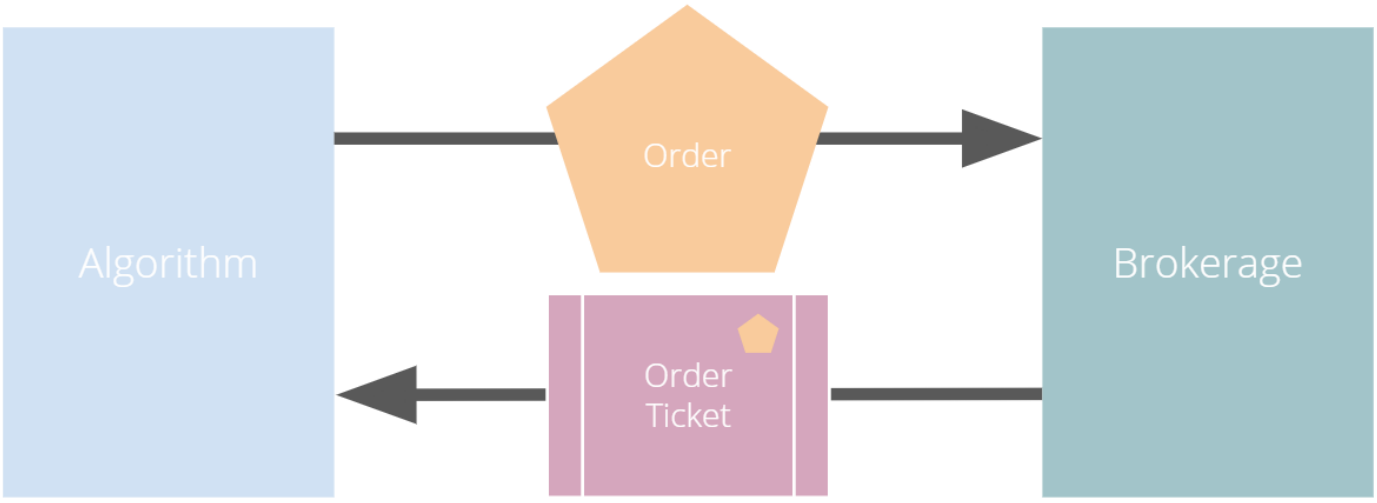
Introduction

LEAN has dozens of methods to create, update, and cancel orders. You can place orders automatically with helper methods or manually through methods on the algorithm API. You can fetch, update, and cancel manual orders with order tickets . As the state of your orders change, LEAN creates events that notify your algorithm.

In backtesting, LEAN simulates order fills with historical data, but you can create your own fill, fee, slippage, and margin models via plugin points. You control how optimistic or pessimistic order fills are with transaction model classes. For more information about these types of models, see Reality Modeling .

Orders and Tickets

When you call one of the order methods to place an order, LEAN performs pre-order checks to ensure that the order meets some requirements and uses the last known price to check you have enough capital . To see the requirements of each order, see the **Requirements** section of the documentation for the order types and the **Orders** section of your brokerage model . If you can place the order, LEAN creates `Order` and OrderTicket objects. The order ticket is sent to your brokerage. As the brokerage processes your order, it returns another order ticket and it's compared against the order to see if the order is satisfied. Orders are asynchronous in live trading, so if you want to change an order, you must request it with the order ticket. Order changes are not guaranteed since your order may fill by the time brokerage receives the request.



Order Types

LEAN supports the following order types:

- Market
- Limit
- Limit if touched
- Stop market
- Stop limit
- Market on open
- Market on close
- Combo market
- Combo limit
- Combo leg limit
- Option exercise

Symbol Properties

The `SymbolProperties` are a property of the `Security` object. LEAN uses some of the `SymbolProperties` to prevent invalid orders, and to calculate order quantities for a given target.

`SymbolProperties` objects have the following properties:

To get the `SymbolProperties` , use the property on the `Security` object.

```py
symbol_properties = self.Securities["BTCUSD"].SymbolProperties
lot_size = symbol_properties.LotSize
minimum_order_size = symbol_properties.MinimumOrderSize
minimum_price_variation = symbol_properties.MinimumPriceVariation
```

LEAN uses the `MinimumPriceVariation` to round the `LimitPrice` , `StopPrice` , and the `TriggerPrice` .

Quote Currency

The quote currency is the currency you must give the seller to buy an asset. For currency trades, the quote currency is the currency ticker on the right side of the currency pair. For other types of assets, the quote currency is usually USD, but the quote currency for India Equities is INR. To get the quote currency of a `Security` , use the `QuoteCurrency` property.

```py
aapl_quote_currency = self.Securities["AAPL"].QuoteCurrency # USD
btcusdt_quote_currency = self.Securities["BTCUSDT"].QuoteCurrency # USDT
```

The `QuoteCurrency` is a `Cash` object, which have the following properties:

You can use the `ConversionRate` property to calculate the value of the minimum price movement in the account currency

```
cfd = self.Securities["SG30SGD"]
quote_currency = cfd.QuoteCurrency # SGD
contract_mutiplier = cfd.SymbolProperties.ContractMultiplier
minimum_price_variation = cfd.SymbolProperties.MinimumPriceVariation

# Value of a pip in account currency
pip = minimum_price_variation * contract_mutiplier * quote_currency.ConversionRate
```

Trade Models

Reality models make backtests as realistic as possible to how the strategy would perform in live trading.

Split Adjustment

If a split event occurs before your order is filled, the unfilled portion of the order is adjusted automatically, where its quantity is multiplied by the split factor and the limit/stop/trigger price (if any) is divided by the split factor.

Live Trading Considerations

In live trading, orders fill asynchronously. We send your order to the API of your brokerage and wait for their response to update the state of your algorithm and portfolio. The timing of live order fills doesn't depend on the resolution of your security subscriptions. When your order fills, the fill price and fee is set by your brokerage. You can add event handlers to your algorithm to monitor the brokerage connection and brokerage messages .

In backtesting, the trade fill timing depends on the resolution of your security subscription. For example, if you subscribe to a security with minute resolution data, the algorithm only receives data in one-minute time slices . As a result, the fill model can only evaluate if the order should fill on a minute-by-minute frequency.

Trading and Orders

Order Management

Order Management

Order Tickets

Introduction

When you create an order, you get an `OrderTicket` object to manage your order.

Properties

`OrderTicket` objects have the following attributes:

Track Orders

As the state of your order updates over time, your order ticket automatically updates. To track an order, you can check any of the preceding order ticket properties.

To get an order field, call the `Get` method with an `OrderField` .

```
limit_price = ticket.Get(OrderField.LimitPrice)
```

PY

The `OrderField` enumeration has the following members:

In addition to using order tickets to track orders, you can receive order events through the `OnOrderEvent` event handler.

Update Orders

To update an order, use its `OrderTicket` . You can update other orders until they are filled or the brokerage prevents modifications. You just can't update orders during warm up and initialization .

Updatable Properties

The specific properties you can update depends on the order type. The following table shows the properties you can update for each order type.

Order Type	Updatable Properties				
	Tag	Quantity	LimitPrice	TriggerPrice	StopPrice
Market Order					
Limit Order	✓	✓	✓		
Limit If Touched Order	✓	✓	✓	✓	
Stop Market Order	✓	✓			✓
Stop Limit Order	✓	✓	✓		✓
Market On Open Order	✓	✓			
Market On Close Order	✓	✓			

Update Methods

To update an order, pass an `UpdateOrderFields` object to the `Update` method. The method returns an `OrderResponse` to signal the success or failure of the update request.

```py
 # Create an order
ticket = self.LimitOrder("SPY", 100, 221.05, False, "New SPY trade")

# Update the order tag and limit price
updateSettings = UpdateOrderFields()
updateSettings.LimitPrice = 222.00
updateSettings.Tag = "Limit Price Updated for SPY Trade"
response = ticket.Update(updateSettings)

# Check the OrderResponse
if response.IsSuccess:
    self.Debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateStopPrice`
- `UpdateTag`

```py
response = ticket.UpdateLimitPrice(limitPrice, tag)

response = ticket.UpdateQuantity(quantity, tag)

response = ticket.UpdateStopPrice(stopPrice, tag)

response = ticket.UpdateTag(tag)
```

Update Order Requests

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
update_requests = ticket.UpdateRequests()
```

Workaround for Brokerages That Don't Support Updates

Not all brokerages fully support order updates. To check what functionality your brokerage supports for order updates, see the **Orders** section of the documentation for your brokerage model . If your brokerage doesn't support order updates and you want to update an order, cancel the order . When you get an order event that confirms the order is no longer active, place a new order.

```
def OnData(self, slice: Slice) -> None:
    # Cancel the order
    self.ticket.Cancel()

def OnOrderEvent(self, orderEvent: OrderEvent) -> None:
    if self.ticket is not None \
        and orderEvent.OrderId == self.ticket.OrderId \
        and orderEvent.Status == OrderStatus.Canceled:
        # Place a new order
        quantity = self.ticket.Quantity - self.ticket.QuantityFilled
        limit_price = self.Securities[self.ticket.Symbol].Price + 1
        self.ticket = self.LimitOrder(self.ticket.Symbol, quantity, limit_price)
```

Cancel Orders

To cancel an order, call the `Cancel` method on the `OrderTicket` . The method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
 # Create an order and save its ticket
ticket = self.LimitOrder("SPY", 100, 221.05, False, "SPY Trade to Cancel")

# Cancel the order
response = ticket.Cancel("Canceled SPY Trade")

# Use the order response object to read the status
if response.IsSuccess:
    self.Debug("Order successfully canceled")
```

You can't cancel market orders because they are immediately transmitted to the brokerage. You also can't cancel any orders during warm up and initialization .

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.CancelOrderRequest()
```

Order Response

When you update or cancel an order, LEAN returns an `OrderReponse` object, which have the following attributes:

If your order changes fail, check the `ErrorCode` or `ErrorMessage` . For more information about specific order errors, see the Order Response Error Reference .

To get most recent order response, call the `GetMostRecentOrderResponse` method.

```
response = ticket.GetMostRecentOrderResponse()
```
PY

Examples

Demonstration Algorithms
OrderTicketDemoAlgorithm.py Python

Order Management

Transaction Manager

Introduction

The algorithm transactions manager (`SecurityTransactionManager`) contains a collection of helper methods to quickly access all your orders. To access the transaction manager, use the `Transactions` property of your algorithm. If you save a reference to your order tickets , you shouldn't need to use the transaction manager. LEAN updates the order tickets as the brokerage processes your orders.

Get a Single Order Ticket

If you didn't save a reference to the order ticket when you created an order, you can call the `GetOrderTicket` method to get it. You need to pass the order ID to the method. If you don't have the order ID, you can use the `LastOrderId` property to get the order ID of the most recent order.

```
PY
order_id = self.Transactions.LastOrderId
ticket = self.Transactions.GetOrderTicket(order_id)
```

Get Order Tickets

To get order tickets, call the `GetOrderTickets` or `GetOpenOrderTickets` method. You can pass in a filter function to filter all of the order tickets or pass a `Symbol` to get the order tickets for a specific asset.

```
PY
# Get all order tickets
order_tickets = self.Transactions.GetOrderTickets()

# Get order tickets that pass a filter
filtered_order_tickets = self.Transactions.GetOrderTickets(lambda order_ticket: order_ticket.Symbol ==
symbol)

# Get all open order tickets
open_order_tickets = self.Transactions.GetOpenOrderTickets()

# Get all open order tickets for a symbol
symbol_open_order_tickets = self.Transactions.GetOpenOrderTickets(symbol)

# Get open order tickets that pass a filter
filtered_open_order_tickets = self.Transactions.GetOpenOrderTickets(lambda order_ticket:
order_ticket.Quantity > 10)
```

Get a Single Order

To get a clone of a specific order, call the `GetOrderById` method with the order Id. To get the order Id, use the `OrderId` property of the order ticket or use the `LastOrderID` property if you want the most recent order.

```
PY
order_id = self.Transactions.LastOrderID
order = self.Transactions.GetOrderById(order_id)
```

Order objects are immutable and changes to the order object will not impact the trade. To make an update to an order you must use Order Tickets . `Order` objects have the following attributes:

Get Orders

To get a list of orders, call the `GetOrders` , `GetOpenOrders` , or `GetOrdersByBrokerageId` method. These method returns a list of `Order` objects.

```PY
# Get all completed orders
completed_Orders = self.Transactions.GetOrders()

# Get all completed orders that pass a filter
filtered_completed_orders = self.Transactions.GetOrders(lambda x: x.Quantity > 10)

# Retrieve a list of all completed orders for a symbol
symbol_completed_orders = self.Transactions.GetOrders(lambda x: x.Symbol == symbol)

# Get all open orders
open_orders = self.Transactions.GetOpenOrders()

# Get all open orders that pass a filter
filtered_open_orders = self.Transactions.GetOpenOrders(lambda x: x.Quantity > 10)

# Retrieve a list of all open orders for a symbol
symbol_open_orders = self.Transactions.GetOpenOrders(symbol)

# Get all open and completed orders that correspond to an Id that the brokerage assigned in live trading
orders_by_brokerage_id = self.Transactions.GetOrdersByBrokerageId(brokerageId)
```

`Order` objects have the following attributes:

The `OrdersCount` property gets the current number of orders that have been processed.

Get Remaining Order Quantity

To get the unfilled quantity of open orders, call the `GetOpenOrdersRemainingQuantity` method.

```PY
# Get the quantity of all open orders
all_open_quantity = self.Transactions.GetOpenOrdersRemainingQuantity()

# Get the quantity of open orders that pass a filter
filtered_open_quantity = self.Transactions.GetOpenOrdersRemainingQuantity(
    lambda order_ticket: order_ticket.Quantity > 10
)

# Get the quantity of open orders for a symbol
symbol_open_quantity = self.Transactions.GetOpenOrdersRemainingQuantity(symbol)
```

Cancel Orders

To cancel open orders, call the `CancelOpenOrders` method. This method returns a list of `OrderTicket` objects that correspond to the canceled orders.

```PY
 # Cancel all open orders
all_cancelled_orders = self.Transactions.CancelOpenOrders()

# Cancel orders related to IBM and apply a tag
ibm_cancelled_orders = self.Transactions.CancelOpenOrders("IBM", "Hit stop price")
```

Market Orders

Introduction

Market orders are instructions to trade a specific number of units, regardless of the fill price. If your highest priority is to fill an order as fast as possible, use market orders. If the order book of the security you're trading has sufficient liquidity when the brokerage receives your order, it immediately fills. However, if there is not enough liquidity by the brokerage, you get partial fills and may incur additional costs from market impact.

Place Orders

To send a market order, call the `MarketOrder` , `Buy` , or `Order` method and provide a `Symbol` and quantity. If you don't have sufficient capital for the order, it's rejected. By default, market orders are synchronous and fill immediately.

```py
# Buy orders
self.MarketOrder("IBM", 100)
self.Buy("AAPL", 10)
self.Order("SPY", 20)

# Sell orders
self.MarketOrder("AMZN", -15)
self.Sell("TSLA", 25)
self.Order("SPY", -20)
```

You can also provide a tag and order properties to the `Order` and `MarketOrder` methods.

```py
self.MarketOrder(symbol, quantity, tag=tag, orderProperties=order_properties)
```

If you place a market order during pre-market or post-market hours, LEAN converts your order to market on open order. To override this behavior, create a custom fill model . To be notified when the default fill model allows you to submit market orders outside of regular trading hours, subscribe to GitHub Issue #3947 .

Monitor Order Fills

If the brokerage has sufficient liquidity in their order book, market orders fill immediately. Otherwise, you get partial fills. To monitor the fills of your order, save a reference to the order ticket .

```py
ticket = self.MarketOrder("XLK", 10)
self.Debug(f"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Synchronous Timeouts

Market orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of

code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `Transactions.MarketOrderFillTimeout` property.

```
 # Adjust the market fill-timeout to 30 seconds.
self.Transactions.MarketOrderFillTimeout = timedelta(seconds=30)
```

Place Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders, set the `asynchronous` argument to true.

```
self.MarketOrder("IBM", 100, True)
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with market orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for market orders, see the **Orders** section of the brokerage model documentation .

Requirements

Market orders must be submitted during market hours for all security types.

If your algorithm place market orders at or after the last minute of regular market hours, they will be converted into market-on-open orders and will have to observe their for the following asset types:

1. Equities
2. Equity Options
3. Forex
4. CFDs
5. Index Options

Market orders for Futures and Future Options can be submitted during extended market hours, or they will be invalid.

Example

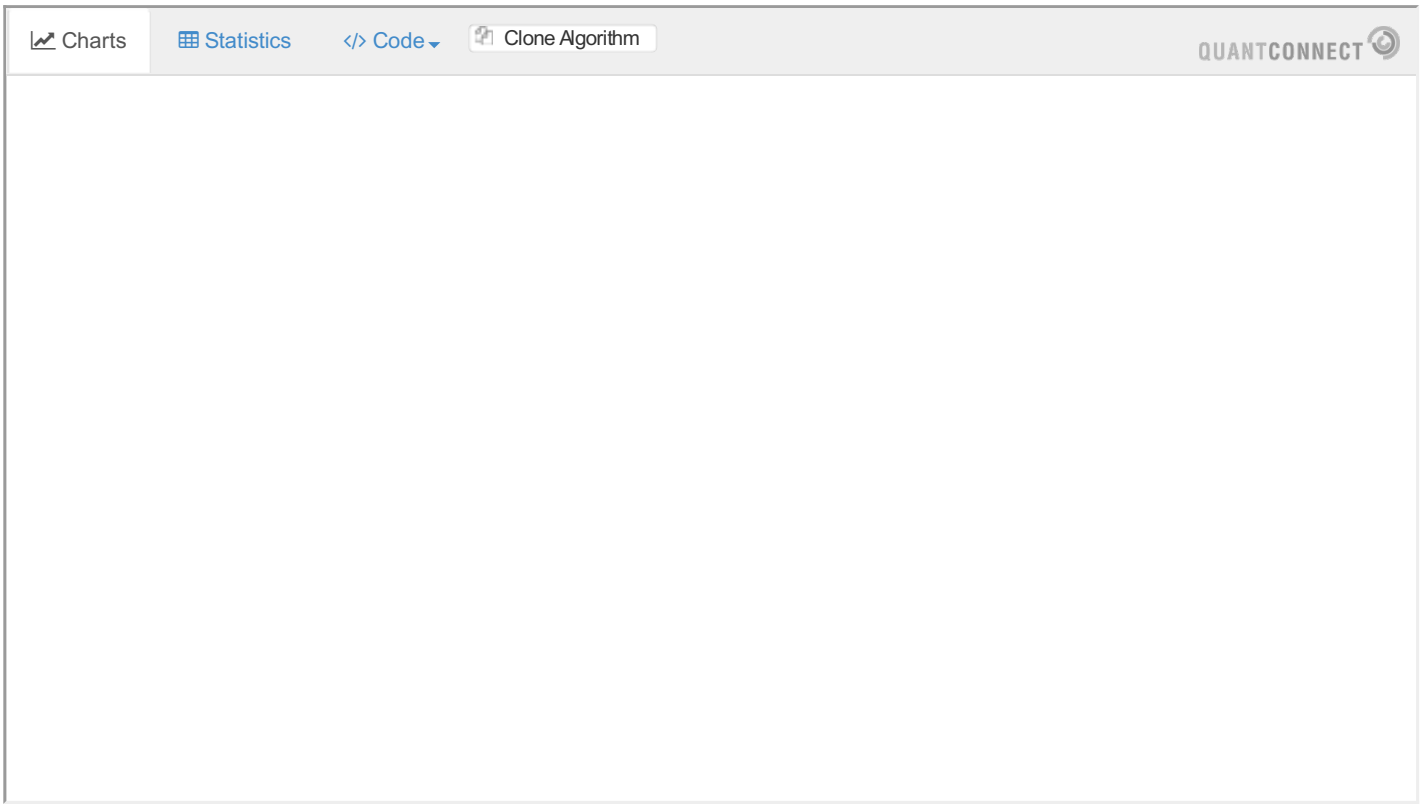
The following backtest verifies the `MarketOrder` behavior. The algorithm buys SPY on the first day and liquidates the position on the second day. The following table shows the first two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	SPY	429.11	10	Market	Filled	4291.10	
2021-07-02T09:31:00Z	SPY	431.54	-10	Market	Filled	-4315.40	

On July 1, 2021, the algorithm buys SPY at $429.11. The fill model fills this order at the ask close price.

On July 2, 2021, the algorithm sells the SPY holdings at $431.54. The fill model fills this order at the bid close price.

To reproduce these results, backtest the following algorithm:



Order Types

Limit Orders

Introduction

Limit orders are instructions to trade a quantity of an asset at a specific price or a better price. A **marketable limit order** has a limit price that crosses the spread. An **unmarketable limit order** has a limit price that doesn't cross the spread. For example, if an asset has an ask price of 100*andyouplacealimitordertobuyat*100 or higher, that's a marketable limit order that should immediately fill. If you place a limit order to buy at $99.99 or lower, that's an unmarketable limit order that should go on the order book. Unmarketable limit orders save you from paying spread costs. Some brokerages even charge you a lower transaction fee if you use unmarketable limit orders rather than marketable limit orders.

Limit orders are helpful in illiquid markets. You can use them to get a good entry price or to set a take-profit level on an existing holding. However, if the market trades away from your limit price, you may have to adjust your limit price or wait for the market to trade back to your limit price to fill the order.

Place Orders

To send a limit order, call the `LimitOrder` method with a `Symbol` , quantity, and limit price. You can also provide a tag and order properties to the `LimitOrder` method. If you do not have sufficient capital for the order, it's rejected.

```
self.LimitOrder(symbol, quantity, limitPrice, tag, orderProperties)
```

PY

To buy an asset with a marketable limit order, set the limit price to the current ask price or higher.

To sell an asset with a marketable limit order, set the limit price to the current bid price or lower.

To buy an asset with an unmarketable limit order, set the limit price below the current ask price.

```
# Buy 1 Bitcoin when the price drops to $34,000
self.LimitOrder("BTCUSD", 1, 34000)
```

PY

To sell an asset with an unmarketable limit order, set the limit price above the current bid price.

```
# Sell 1 Bitcoin when the price moves up to $60,000
self.LimitOrder("BTCUSD", -1, 60000)
```

Monitor Order Fills

Limit orders fill when the security price passes the limit price. To monitor the fills of your order, save a reference to the order ticket .

```
# Buy 10 shares of XLK at $140
ticket = self.LimitOrder("XLK", 10, 140)
self.Debug(f"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of limit orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.LimitOrder("SPY", 100, 221.05, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.Quantity = 80
update_settings.LimitPrice = 222.00
update_settings.Tag = "new tag"
response = ticket.Update(update_settings)

# Check if the update was successful
if response.IsSuccess:
    self.Debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateTag`

```
response = ticket.UpdateLimitPrice(limitPrice, tag)

response = ticket.UpdateQuantity(quantity, tag)

response = ticket.UpdateTag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
update_requests = ticket.UpdateRequests()
```

Cancel Orders

To cancel a limit order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.Cancel("Cancelled Trade")
if response.IsSuccess:
    self.Debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns

`None` if the order hasn't been cancelled.

```
request = ticket.CancelOrderRequest()
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with limit orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for limit orders, see the **Orders** section of the brokerage model documentation .

Requirements

Limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Example

The following backtest verifies the `LimitOrder` behavior. On the first day, the algorithm buys SPY with an unmarketable limit order. On the second day, the algorithm sells SPY with an unmarketable limit order and places another unmarketable limit order to buy SPY, which doesn't fill. The following table shows the first three trades in the backtest:

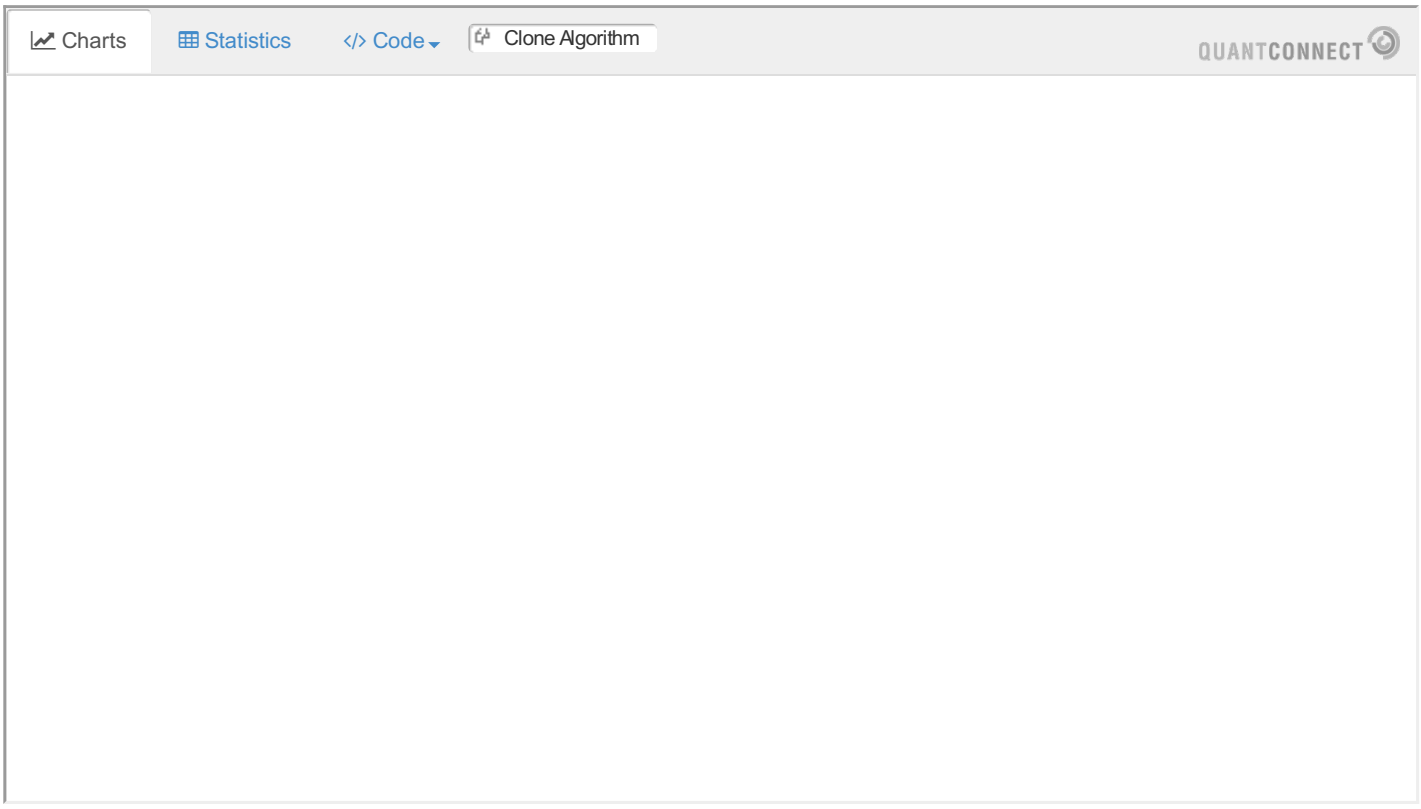
Submitted Time	Filled Time	Symbol	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:32:00Z	SPY	429.00	429.00	10	Limit	Filled	4290.00	Limit Price: ¤429.00
2021-07-02T09:31:00Z	2021-07-02T09:35:00Z	SPY	431.70	431.70	-10	Limit	Filled	-4317.00	Limit Price: ¤431.70
2021-07-02T09:31:00Z	/	SPY	400.00	/	10	Limit	Submitted	/	Limit Price: ¤400.00

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a buy limit order with a limit price of 429*whentheasklowpriceis*428.81 and the ask high price is 429.15.*Theorderfillsat*9:32*AMETatapriceof*429. The fill model fills buy limit orders when the ask low price is less than the limit price. It sets the fill price of the order to the minimum of ask high price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a sell limit order at 431.70*andabuylimitorderat*400. At the time of the order, the bid high price is 431.65, *thebidlowpriceis*431.49, and the ask low price is 431.50.*Thesellimitorderfillsat*9:35*AMETatapriceof*431.70 and the buy limit order doesn't fill. The fill model fills sell limit order when the bid high price is greater than the limit price. It sets the fill price of the order to the maximum of the bid

low price and the limit price. The buy limit order doesn't fill because the ask low price is above the limit price for the remainder of the backtest period.

To reproduce these results, backtest the following algorithm:



Order Types

Limit if Touched Orders

Introduction

Limit if touched (LIT) orders are instructions to place a limit order once an asset touches a specific price level. A buy LIT order has a trigger price below the current market price and a sell LIT order has a trigger price above the current market price. In effect, LIT orders are the opposite of stop limit orders .

Place Orders

To send a LIT order, call the `LimitIfTouchedOrder` method and provide a `Symbol` , quantity, trigger price, and limit price. You can also provide a tag and order properties to the `LimitIfTouchedOrder` method. If you do not have sufficient capital for the order, it's rejected.

```
self.LimitIfTouchedOrder(symbol, quantity, trigger_price, limit_price, tag, order_properties)
```

To buy an asset with a LIT order that has a marketable limit price, set the trigger price below the current market price and set the limit price above the trigger price.

```
# Once Bitcoin trades down to $36,000, place a limit order to buy 1 Bitcoin at $38,000
self.LimitIfTouchedOrder("BTCUSD", 1, 33000, 36000)
```

To sell an asset with a LIT order that has a marketable limit price, set the trigger price above the current market price and set the limit price below the trigger price.

```py
# Once Bitcoin trades up to $62,000, place a limit order to sell 1 Bitcoin at $59,000
self.LimitIfTouchedOrder("BTCUSD", -1, 62000, 59000)
```

To buy an asset with a LIT order that has an unmarketable limit price, set the trigger price below the current market price and set the limit price below the trigger price.

```py
# Once Bitcoin trades down to $46,000, place a limit order to buy 1 Bitcoin at $36,000
self.LimitIfTouchedOrder("BTCUSD", 1, 46000, 36000)
```

To sell an asset with a LIT order that has an unmarketable limit price, set the trigger price above the current market price and set the limit price above the trigger price.

```
# Once Bitcoin trades up to $54,000, place a limit order to sell 1 Bitcoin at $62,000
self.LimitIfTouchedOrder("BTCUSD", -1, 54000, 62000)
```

Monitor Order Fills

LIT orders fill when the security price touches the trigger price and is at least as favorable as the limit price. To monitor the fills of your order, save a reference to the order ticket .

```
# Once SPY trades down to $425, place a limit order to buy 10 shares at $415
ticket = self.LimitIfTouchedOrder("SPY", 10, 425, 415)
self.Debug(f"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, trigger price, limit price, and tag of LIT orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.LimitIfTouchedOrder("SPY", 100, 350, 340, tag="Original tag")

# Update the order
update_order_fields = UpdateOrderFields()
update_order_fields.Quantity = 80
update_order_fields.TriggerPrice = 380
update_order_fields.LimitPrice = 370
update_order_fields.Tag = "New tag"
response = ticket.Update(update_settings)

# Check the OrderResponse
if response.IsSuccess:
    self.Debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateTriggerPrice`
- `UpdateTag`

```
response = ticket.UpdateLimitPrice(limitPrice, tag)
response = ticket.UpdateQuantity(quantity, tag)
response = ticket.UpdateTriggerPrice(triggerPrice, tag)
response = ticket.UpdateTag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
update_requests = ticket.UpdateRequests()
```

Cancel Orders

To cancel a LIT order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.Cancel("Cancelled Trade")
if response.IsSuccess:
    self.Debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.CancelOrderRequest()
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with LIT orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for LIT orders, see the **Orders** section of the brokerage model documentation .

Requirements

LIT orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Example

The following backtest verifies the `LimitIfTouchedOrder` behavior. The following table shows the trades in the backtest:

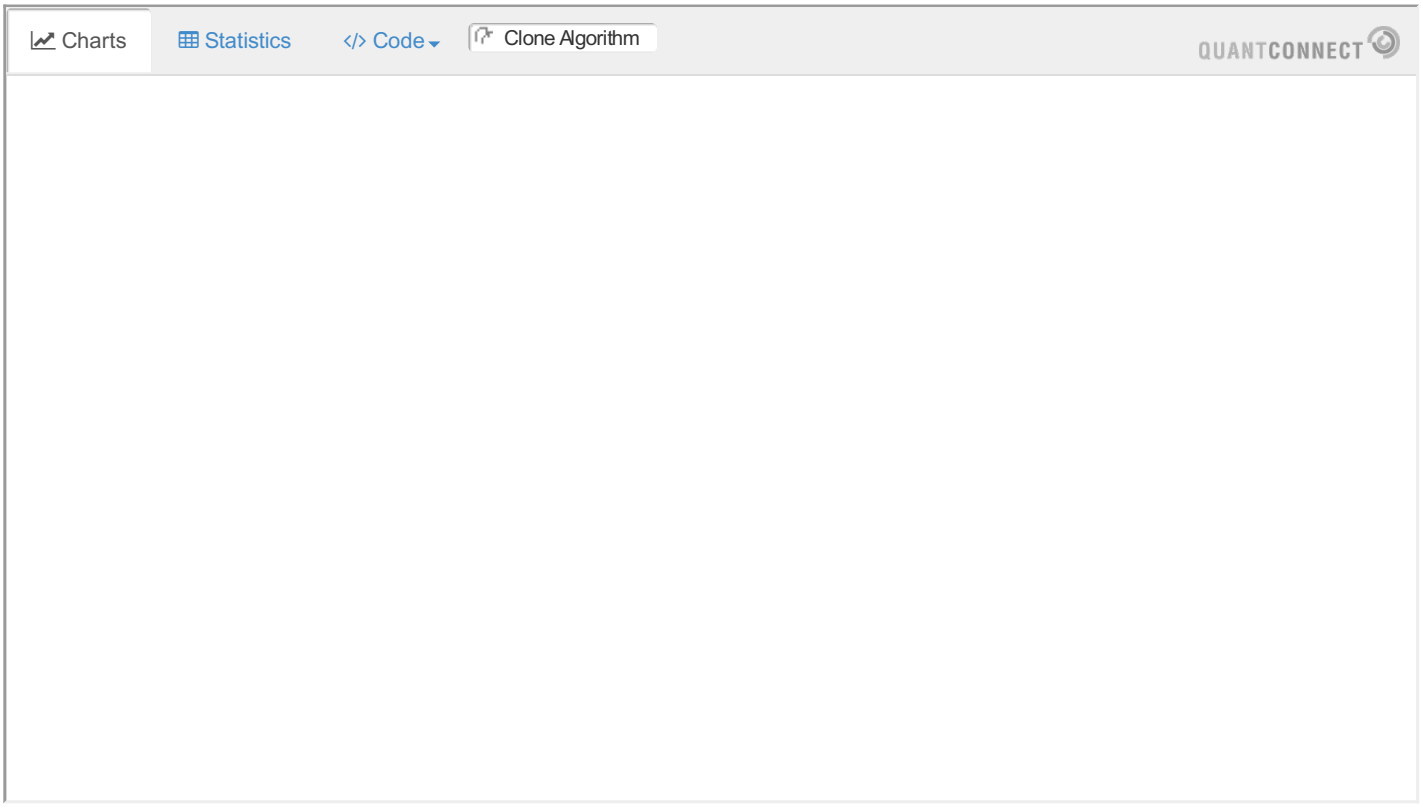
Submitted Time	Filled Time	Symbol	Trigger Price	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:38:00Z	SPY	429.00	428.95	428.95	10	Limit if touched	Filled	4285.00	Trigger Price: ¤429.00 Limit Price: ¤428.95
2021-07-02T09:31:00Z	2021-07-02T09:49:00Z	SPY	431.70	431.75	431.84	-10	Limit if touched	Filled	-4318.40	Trigger Price: ¤431.70 Limit Price: ¤431.75
2021-07-02T09:31:00Z	/	SPY	431.70	400.00	/	10	Limit if touched	Submitted	/	Trigger Price: ¤431.70 Limit Price: ¤400.00
/	/	SPY	400.00	400.00	/	10	Limit if touched	Submitted	/	Trigger Price: ¤400.00 Limit Price: ¤400.00

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a LIT order to buy SPY with a trigger price of 429*andalimitpriceof*428.95. At the time of the order submission, the low price was 428.80*andthebidclosepricewas*429.10. The order fills at 9:38 AM ET at a price of $428.95. The fill model sets the limit price for buy orders when the low price is less than or equal to the trigger price, fills the order when the bid close price is less than or equal to the limit price, and sets the fill price to the minimum of the ask price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a LIT order to sell SPY with a trigger price of 431.70*andalimitpriceof* 431.75. At the time of the order submission, the high price was 431.78*andtheaskclosepricewas*431.55. The order fills at 9:49 AM ET at a price of $431.84. The fill model sets the limit price for sell orders when the high price is greater than or equal to the trigger price, fills the order when the ask close price is greater than or equal to the limit price, and sets the fill price to the maximum of the bid price and the limit price.

On July 2, 2021, the algorithm places a third LIT order to buy SPY with a trigger price of 431.70*andalimitpriceof*400. The fill model sets the fill price, but it doesn't fill the order because the limit price is too low. On the same day, the algorithm places a fourth LIT order to buy SPY with a trigger price of 400*andalimitpriceof*400. The fill model doesn't set the limit price for this order because SPY doesn't touch the trigger price before the backtest ends.

To reproduce these results, backtest the following algorithm:



Order Types

Stop Market Orders

Introduction

Stop market orders fill as a market order when the asset reaches a specific price. A buy stop market order triggers when the asset price is greater than or equal to the stop price. A sell stop market order triggers when the asset price is less than or equal to the stop price. You can use stop market orders to buy breakouts or to mitigate the risk of large losses. However, if the market gaps past your stop price, the order may fill at a worse price than the stop price you set. There is no guarantee that a stop market order fills at the stop price.

Place Orders

To send a stop market order, call the `StopMarketOrder` method and provide a `Symbol` , quantity, and stop price. You can also provide a tag and order properties to the `StopMarketOrder` method. If you do not have sufficient capital for the order, it is rejected.

```py
self.StopMarketOrder(symbol, quantity, stopPrice, tag, orderProperties)
```

To buy an asset with a stop market order, set the stop price above the current ask price.

```py
# When Bitcoin trades up to $60,000, buy 1 Bitcoin
self.StopMarketOrder("BTCUSD", 1, 60000)
```

To sell an asset with a stop market order, set the stop price below the current bid price.

```py
# When Bitcoin trades down to $43,000, sell 1 Bitcoin
self.StopMarketOrder("BTCUSD", -1, 43000)
```

Monitor Order Fills

Stop market orders fill as a market order when the security price passes the stop price. To monitor the fills of your order, save a reference to the order ticket .

```
# When XLK trades down to $130, sell 10 shares
ticket = self.StopMarketOrder("XLK", -10, 130)
self.Debug(f"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, stop price, and tag of stop market orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.StopMarketOrder("SPY", -100, 415, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.Quantity = -80
update_settings.StopPrice = 400
update_settings.Tag = "new tag"
response = ticket.Update(update_settings)

# Check if the update was successful
if response.IsSuccess:
    self.Debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `UpdateQuantity`
- `UpdateStopPrice`
- `UpdateTag`

```
response = ticket.UpdateQuantity(quantity, tag)
response = ticket.UpdateStopPrice(stopPrice, tag)
response = ticket.UpdateTag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
update_requests = ticket.UpdateRequests()
```

Cancel Orders

To cancel a stop market order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.Cancel("Cancelled Trade")
if response.IsSuccess:
    self.Debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.CancelOrderRequest()
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with stop market orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for stop market orders, see the **Orders** section of the brokerage model documentation .

Requirements

Stop market orders can be submitted at any time for all security types.

Example

The following backtest verifies the `StopMarketOrder` behavior. On even days, the algorithm buys SPY at the current market price and sells when the price drops 1%. On odd days, the algorithm shorts SPY and buys when the price rises 1%. The following table shows the first four trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T13:31:00Z	SPY	429.10	-1	Market	Filled	-429.10	
2021-07-01T13:31:00Z	SPY	433.44	1	Stop Market	Filled	433.44	Stop Price: 433.43
2021-07-02T17:04:00Z	SPY	433.44	1	Market	Filled	433.44	
2021-07-02T17:04:00Z	SPY	429.00	-1	Stop Market	Filled	-429.00	Stop Price: 429.10

On July 1, 2021, the algorithm shorts SPY at 429.10*andthenbuysitbackat*433.44 when the stop price is 433.43.*Thestoppriceis*1429.10 is not the market price when the algorithm places the first two orders. 429.10*isthefillpriceatthebid*, *butit*'*snotfarfromthemarketpricebecause*429.1 □ 1.01 = 433.39.*Thefillpriceofthestopmarketorderis* 433.44, which, as expected, is higher than $433.43. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the maximum of the market price and stop price.

On July 2, 2021, the algorithm buys SPY at 433.44*andsellsitat*429 when the stop price is 429.10.*Thestoppriceis*1433.44 is not the market price when the algorithm places the second two orders. 433.44*isthefillpriceattheask*, *butit*'*snotfarofffromthemarketpricebecause*433.44 □ 0.99 = 429.11.*Thefillpriceofthestopmarketorderis* 429, which, as expected, is lower than $429.10. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the minimum of the market price and stop price.

Order Types

Stop Limit Orders

Introduction

Stop limit orders are instructions to place a limit order once an asset passes a specific price level. They are similar to stop market orders , but use limit orders instead of market orders to give you more control over the fill price. A buy stop limit order has a stop price above the current market price and a sell stop limit order has a stop price below the current market price. In effect, they are the opposite of limit if touched orders .

Place Orders

To send a stop limit order, call the `StopLimitOrder` method and provide a `Symbol` , quantity, stop price, and limit price. You can also provide a tag and order properties to the `StopLimitOrder` method. If you do not have sufficient capital for the order, it is rejected.

```py
self.StopLimitOrder(symbol, quantity, stop_rice, limit_price, tag, order_properties)
```

To buy an asset with a stop limit order that has a marketable limit price, set the stop price above the current market price and set the limit price above the stop price.

```py
# When Bitcoin trades up to $59,000, buy 1 Bitcoin with a limit order at $62,000
self.StopLimitOrder("BTCUSD", 1, 59000, 62000)
```

To buy an asset with a stop limit order that has an unmarketable limit price, set the stop price above the current market price and set the limit price below the stop price.

```py
# When Bitcoin trades up to $52,000, buy 1 Bitcoin with a limit order at $41,000
self.StopLimitOrder("BTCUSD", 1, 52000, 41000)
```

To sell an asset with a stop limit order that has an unmarketable limit price, set the stop price below the current market price and set the limit price above the stop price.

```py
# When Bitcoin trades down to $49,000, sell 1 Bitcoin with a limit order at $58,000
self.StopLimitOrder("BTCUSD", -1, 49000, 58000)
```

To sell an asset with a stop limit order that has a marketable limit price, set the stop price below the current market price and set the limit price below the stop price.

```
# When Bitcoin trades down to $37,000, sell 1 Bitcoin with a limit order at $34,000
self.StopLimitOrder("BTCUSD", -1, 37000, 34000)
```

Monitor Order Fills

Stop limit orders fill as limit orders when the security price passes the stop price. To monitor the fills of your order, save a reference to the order ticket .

```
# When GLD trades up to $200, buy 10 shares with a limit order at $205
ticket = self.StopLimitOrder("GLD", 10, 200, 205)
self.Debug(f"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, stop price, limit price, and tag of stop limit orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request..

```
# Create a new order and save the order ticket
ticket = self.StopLimitOrder("SPY", -10, 400, 390, tag="original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.Quantity = -15
update_settings.StopPrice = 415
update_settings.LimitPrice = 395
update_settings.Tag = "new tag"
response = ticket.Update(update_settings)

# Check if the update was successful
if response.IsSuccess:
    self.Debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateStopPrice`
- `UpdateTag`

```
PY
response = ticket.UpdateLimitPrice(limitPrice, tag)
response = ticket.UpdateQuantity(quantity, tag)
response = ticket.UpdateStopPrice(stopPrice, tag)
response = ticket.UpdateTag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
PY
update_requests = ticket.UpdateRequests()
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with stop limit orders, set the brokerage model to a brokerage that supports them.

```
PY
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for stop limit orders, see the **Orders** section of the brokerage model documentation .

Requirements

Stop limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Example

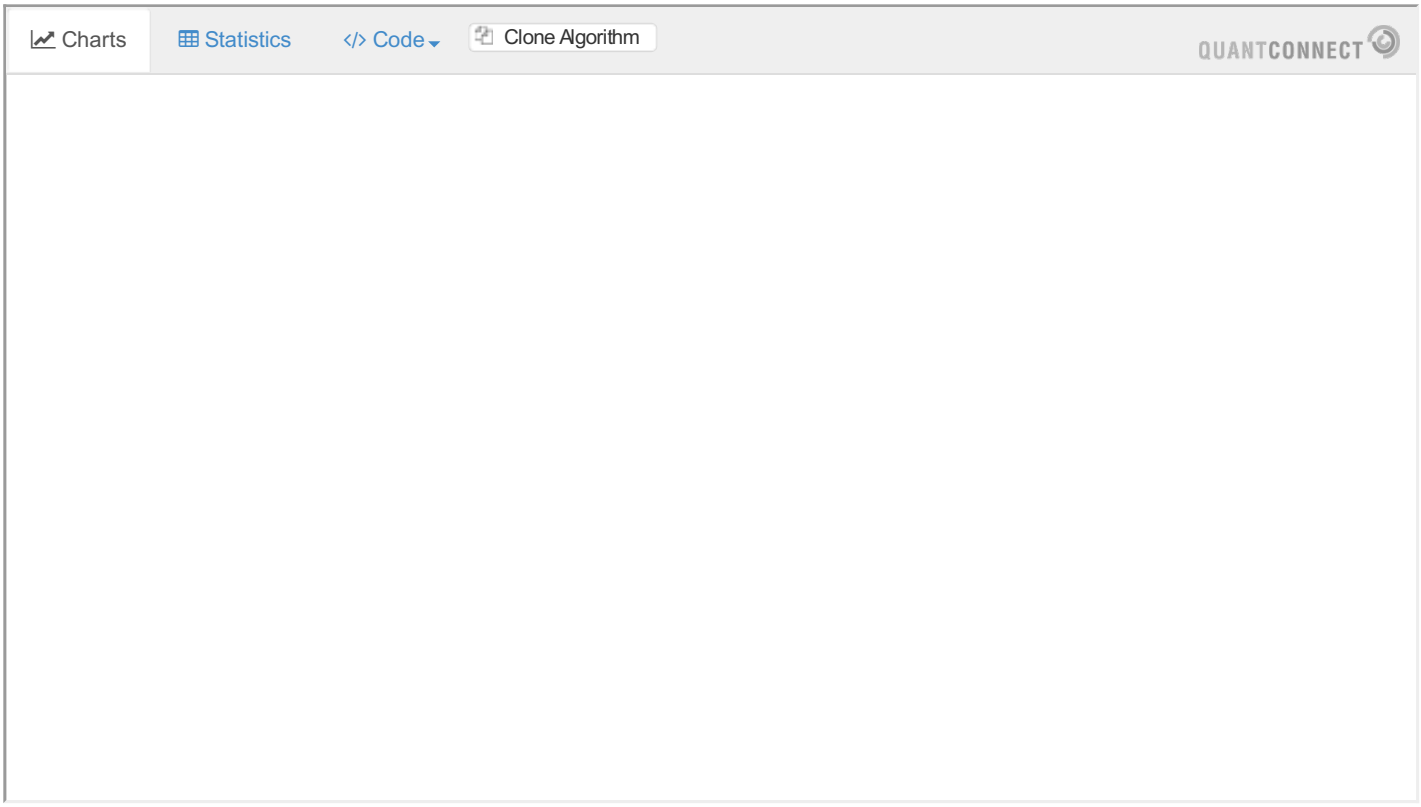
The following backtest verifies the `StopLimitOrder` behavior. The following table shows the trades in the backtest:

Submitted Time	Filled Time	Symbol	Stop Price	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:37:00Z	SPY	428.95	429.00	429.00	-10	Stop Limit	Filled	-4290.00	Stop Price: ¤428.95 Limit Price: ¤429.00
2021-07-02T09:31:00Z	2021-07-02T10:12:00Z	SPY	431.80	431.75	431.75	10	Stop Limit	Filled	4317.50	Stop Price: ¤431.80 Limit Price: ¤431.75

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a stop limit order to sell SPY with a stop price of 428.95*andalimitpriceof*429. At the time of the order submission, the ask high price is 429.16*andtheaskclosepriceis*429.11. The order fills at 9:37 AM ET at a price of $429. The fill model triggers the stop for buy orders when the ask high price is greater than the stop price, fills the order when the ask close price is less than the limit price, and sets the fill price to the maximum of the ask high price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a stop limit order to buy SPY with a stop price of 431.80*andalimitpriceof*431.75. At the time of the order submissions, the bid low price is 431.49*andthebidclosepriceis* 431.54. The order fills at 10:12 AM ET at a price of $431.75. The fill model triggers the stop for sell orders when bid low price is less than the stop price, fills the order when the ask close price is less than the limit price, and sets the fill price to the minimum of the ask high price and the limit price.

To reproduce these results, backtest the following algorithm:



Order Types

Market On Open Orders

Introduction

Market on open (MOO) orders fill at the official opening auction price for a security. Market that operate 24/7 don't support MOO orders.

Place Orders

To send a MOO order, call the `MarketOnOpenOrder` method and provide a `Symbol` and quantity. Submit the order at least two minutes before the market opens to be included in the opening auction. If you do not have sufficient capital for the order, it's rejected.

```py
# Buy 100 shares of IBM at the market open
self.MarketOnOpenOrder("IBM", 100)

# Sell 100 shares of IBM at the market open
self.MarketOnOpenOrder("IBM", -100)
```

You can provide a tag and order properties to the `MarketOnOpenOrder` method.

```py
self.MarketOnOpenOrder(symbol, quantity, tag=tag, orderProperties=order_properties)
```

Monitor Order Fills

MOO orders fill at the opening auction. If the auction is heavily skewed to one side of the market, your MOO order may not fill. To monitor the fills of your order, save a reference to the order ticket .

```py
# Buy 10 shares of SPY at the market open
ticket = self.MarketOnOpenOrder("SPY", 10)
self.Debug(f"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}")
```

You won't know the fill price of the order until after the market opens. If the asset price moves before the market open to where you can't afford the quantity of the order, the brokerage rejects your order. To increase the probability of a successful trade, leave a sufficient buying power buffer to handle daily price gaps.

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity and tag of MOO orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success

or failure of the update request.

```
# Create a new order and save the order ticket
ticket = self.MarketOnOpenOrder("AAPL", 100, "original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.Quantity = 75
update_settings.Tag = "new tag"
response = ticket.Update(update_settings)

# Check if the update was successful
if response.IsSuccess:
    self.Debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `UpdateQuantity`
- `UpdateTag`

```
response = ticket.UpdateQuantity(quantity, tag)

response = ticket.UpdateTag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
update_requests = ticket.UpdateRequests()
```

Cancel Orders

To cancel a MOO order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.Cancel("Cancelled Trade")
if response.IsSuccess:
    self.Debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.CancelOrderRequest()
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with MOO orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for MOO orders, see the **Orders** section of the brokerage model documentation .

Requirements

You can submit MOO orders at any time for Equity, Equity Options, and Index Options.

Markets that operate 24/7 don't support MOO orders. The Forex market doesn't operate during the weekend. However, MOO orders are invalid if you place them after this market closes for the weekend.

MOO orders don't support the `GoodTilDate` time in force . If you submit a MOO order with the `GoodTilDate` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

Example

The following backtest verifies the `MarketOnOpenOrder` behavior. The following table shows the first trade in the backtest:

Submitted Time	Filled Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T10:31:00Z	2021-07-02T09:31:00Z	SPY	431.67	10	Market On Open	Filled	4316.70	

On July 1, 2021 at 10:31 AM Eastern Time (ET), the algorithm places a market on open order to buy SPY. The fill model fills the order on July 2, 2021 at 9:31 AM at a price of $431.67, which is the official opening auction price for July 2, 2021.

To reproduce these results, backtest the following algorithm:

Market On Close Orders

Introduction

Market on close (MOC) orders fill at the official closing auction price for a security. Markets that operate 24/7 don't support MOC orders.

Place Orders

To send a MOC order, call the `MarketOnCloseOrder` method with a `Symbol` and quantity. If you don't have sufficient capital for the order, it is rejected.

```
PY
# Buy 100 shares of AAPL at the market open
self.MarketOnCloseOrder("AAPL", 100)

# Sell 100 shares of AAPL at the market open
self.MarketOnCloseOrder("AAPL", -100)
```

You can provide a tag and order properties to the `MarketOnCloseOrder` method.

```
PY
self.MarketOnCloseOrder(symbol, quantity, tag=tag, orderProperties=order_properties)
```

By default, you must place MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.SubmissionTimeBuffer` property.

```
PY
MarketOnCloseOrder.SubmissionTimeBuffer = timedelta(minutes=10)
```

You can also place MOC orders after the market close.

Monitor Order Fills

MOC orders fill at the closing auction. If the auction is heavily skewed to one side of the market, your MOC order may not fill. To monitor the fills of your order, save a reference to the order ticket .

```
PY
# Buy 10 shares of SPY at the market close
ticket = self.MarketOnCloseOrder("SPY", 10)
self.Debug(f"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}")
```

You won't know the fill price of the order until after the market closes. If the asset price moves before the market close to where you can't afford the quantity of the order, the brokerage rejects your order. To increase the probability of a

successful trade, leave a sufficient buying power buffer to handle the price movements before the close.

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity and tag of MOC orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
PY
# Create a new order and save the order ticket
ticket = self.MarketOnOpenOrder("SLV", 25, "original tag")

# Update the order
update_settings = UpdateOrderFields()
update_settings.Quantity = 50
update_settings.Tag = "new tag"
response = ticket.Update(update_settings)

# Check if the update was successful
if response.IsSuccess:
    self.Debug("Order updated successfully")
```

To update individual fields of an order, call any of the following methods:

- `UpdateQuantity`
- `UpdateTag`

```
PY
response = ticket.UpdateQuantity(quantity, tag)

response = ticket.UpdateTag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
PY
update_requests = ticket.UpdateRequests()
```

Cancel Orders

To cancel a MOC order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
PY
response = ticket.Cancel("Cancelled Trade")
if response.IsSuccess:
    self.Debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.CancelOrderRequest()
```

PY

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with MOC orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

PY

To check if your brokerage has any special requirements for MOC orders, see the **Orders** section of the brokerage model documentation .

Requirements

By default, you must place MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.SubmissionTimeBuffer` property.

```
MarketOnCloseOrder.SubmissionTimeBuffer = timedelta(minutes=10)
```

PY

Markets that operate 24/7 don't support MOC orders. The Forex market doesn't operate during the weekend.

MOC orders don't support the `GoodTilDate` time in force . If you submit a MOC order with the `GoodTilDate` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

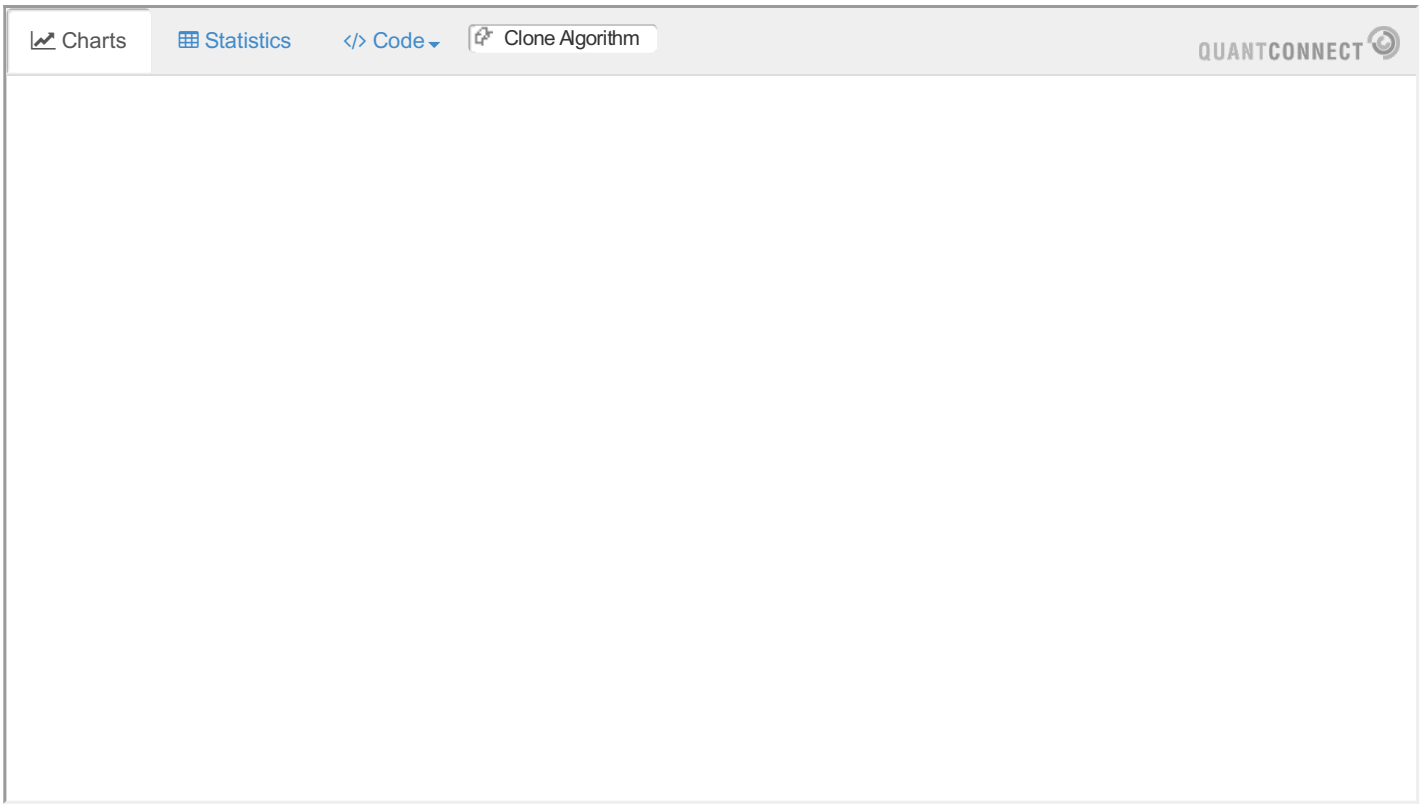
Example

The following backtest verifies the `MarketOnCloseOrder` behavior. The following table shows the first trade in the backtest:

Submitted Time	Filled Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T10:31:00Z	2021-07-01T16:00:00Z	SPY	430.43	10	Market On Close	Filled	4304.30	

On July 1, 2021 at 10:31 AM Eastern Time (ET), the algorithm places a market on open order to buy SPY. The fill model fills the order on July 1, 2021 at 4:00 PM ET at a price of $430.43, which is the official closing auction price for July 1, 2021.

To reproduce these results, backtest the following algorithm:



Charts
Statistics
Code
Clone Algorithm
QUANTCONNECT

Order Types

Combo Market Orders

Introduction

Combo market orders are individual orders that contain market orders for muliple securities. Combo market orders currently only work for trading Option contracts.

Place Orders

To send a combo market order, create multiple `Leg` objects to represent the legs of the combo order, then call the `ComboMarketOrder` method. At least one leg must have a positive quantity and at least one leg must have a negative quantity. The legs must each target a unique contract. If you don't have sufficient capital for the order, it's rejected. By default, combo market orders are synchronous and fill immediately.

```
PY
for canonical_symbol, chain in slice.OptionChains.items():
    # Select contracts
    contracts = [c for c in chain][:2]
    if len(contracts) < 2:
        return

    # Create order legs
    legs = []
    quantities = [1, -1]
    for i, contract in enumerate(contracts):
        legs.append(Leg.Create(contract.Symbol, quantities[i]))

    # Place order
    self.ComboMarketOrder(legs, 1)
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `ComboMarketOrder` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity argument of the `ComboMarketOrder` method also sets the order direction of the combo order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `ComboMarketOrder` method.

```
PY
self.ComboMarketOrder(legs, quantity, tag=tag, orderProperties=order_properties)
```

Monitor Order Fills

If the brokerage has sufficient liquidity in their order book, combo market orders fill immediately. Otherwise, you get partial fills. To monitor the fills of your order, save a reference to the order tickets .

```
ticket = self.ComboMarketOrder(legs, 1)
for ticket in tickets:
    self.Debug(f"Symbol: {ticket.Symbol}; Quantity filled: {ticket.QuantityFilled}; Fill price:
{ticket.AverageFillPrice}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Synchronous Timeouts

Combo market orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `Transactions.MarketOrderFillTimeout` property.

```
 # Adjust the market fill-timeout to 30 seconds.
self.Transactions.MarketOrderFillTimeout = timedelta(seconds=30)
```

Place Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders, set the `asynchronous` argument to true.

```
self.ComboMarketOrder(legs, quantity, True)
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo market orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for combo market orders, see the **Orders** section of the brokerage model documentation .

Requirements

Combo market orders must be submitted during market hours for all security types.

If your algorithm place combo market orders at or after the last minute of regular market hours, they will be converted into market-on-open orders and will have to observe their for the following asset types:

1. Equities
2. Equity Options
3. Forex
4. CFDs
5. Index Options

Combo market orders for Futures and Future Options can be submitted during extended market hours, or they will be invalid.

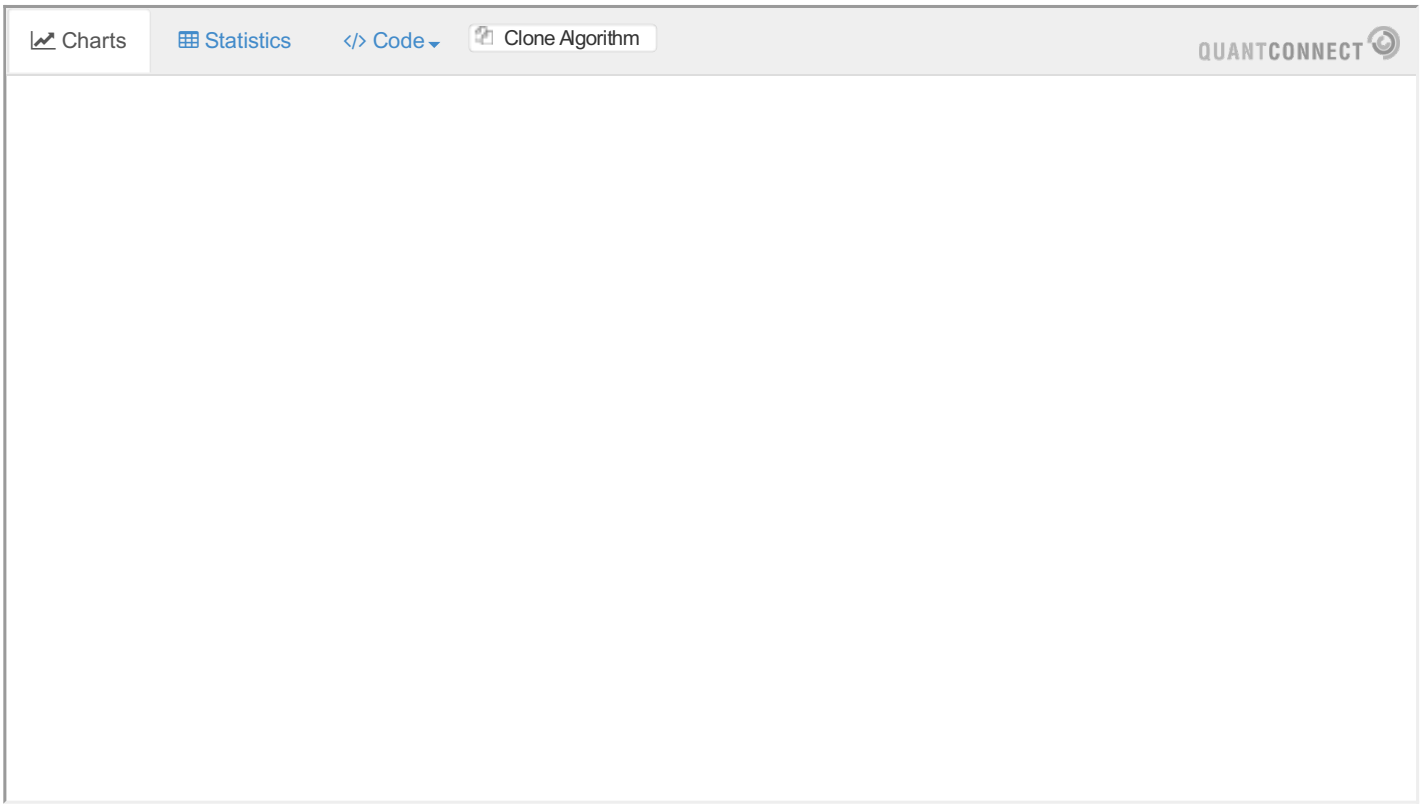
Example

The following backtest verifies the `ComboMarketOrder` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 16011SC00745000	16.90	1	Buy	Filled	16.90	
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.20	-1	Sell	Filled	-14.20	

On December 24, 2015, the algorithm buys GOOG 16011SC00745000 at 16.90*and*sells*GOOG*160115*C*00747500*at*14.20. The fill model fills the buy order at the ask close price and fills the sell order at the bid close price.

To reproduce these results, backtest the following algorithm:



Order Types

Combo Limit Orders

Introduction

Combo limit orders are individual orders that contain limit orders for muliple securities. Combo limit orders are different from combo leg limit orders because you must set the limit price of all the leg orders to be the same with combo limit orders. With combo leg limit orders, you can create the order without forcing each leg to have the same limit price. Combo limit orders currently only work for trading Option contracts and their underlying Equities.

Place Orders

To send a combo limit order, create multiple `Leg` objects to represent the legs of the combo order, then call the `ComboLimitOrder` method. At least one leg must have a positive quantity and a tleast one leg must have a negative quantity. The legs must each target a unique contract, but don't set the `OrderPrice` property for any of the legs. If you don't have sufficient capital for the order, it's rejected.

```py
for canonical_symbol, chain in slice.OptionChains.items():
    # Select contracts
    contracts = [c for c in chain][:2]
    if len(contracts) < 2:
        return

    # Create order legs
    legs = []
    quantities = [1, -1]
    for i, contract in enumerate(contracts):
        legs.append(Leg.Create(contract.Symbol, quantities[i]))

    # Calculate limit price
    limit_price = round(sum([self.Securities[leg.Symbol].Close for leg in legs]) * 0.95, 2)

    # Place order
    self.ComboLimitOrder(legs, 1, limit_price)
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `ComboLimitOrder` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity also sets the order direction of the combo limit order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `ComboLimitOrder` method.

```py
self.ComboLimitOrder(legs, quantity, limit_price, tag=tag, orderProperties=order_properties)
```

Monitor Order Fills

Combo limit orders fill all the legs at the same time. Each leg can fill when the sum of the security prices of the legs pass the limit price of the combo order. To monitor the fills of your order, save a reference to the order tickets .

```
tickets = self.ComboLimitOrder(legs, 1, limit_price)
for ticket in tickets:
    self.Debug(f"Symbol: {ticket.Symbol}; Quantity filled: {ticket.QuantityFilled}; Fill price:
{ticket.AverageFillPrice}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of the limit orders in each leg until the combo order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . To update the limit price of the combo order, you only need to update the limit price of one of the leg orders. The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order tickets
tickets = self.ComboLimitOrder(legs, 1, limit_price)

# Update the leg orders
for ticket in tickets:
    update_settings = UpdateOrderFields()
    update_settings.Quantity = 2 * np.sign(ticket.Quantity)
    update_settings.LimitPrice = ticket.Get(OrderField.LimitPrice) + 0.01
    update_settings.Tag = f"Update #{len(ticket.UpdateRequests) + 1}"
    response = ticket.Update(update_settings)

    # Check if the update was successful
    if response.IsSuccess:
        self.Debug(f"Order updated successfully for {ticket.Symbol}")
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateTag`

```
response = ticket.UpdateLimitPrice(limitPrice, tag)

response = ticket.UpdateQuantity(quantity, tag)

response = ticket.UpdateTag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
update_requests = ticket.UpdateRequests()
```

Cancel Orders

To cancel a combo limit order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it

from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.Cancel("Cancelled Trade")
if response.IsSuccess:
    self.Debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.CancelOrderRequest()
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo limit orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for combo limit orders, see the **Orders** section of the brokerage model documentation .

Requirements

Combo limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

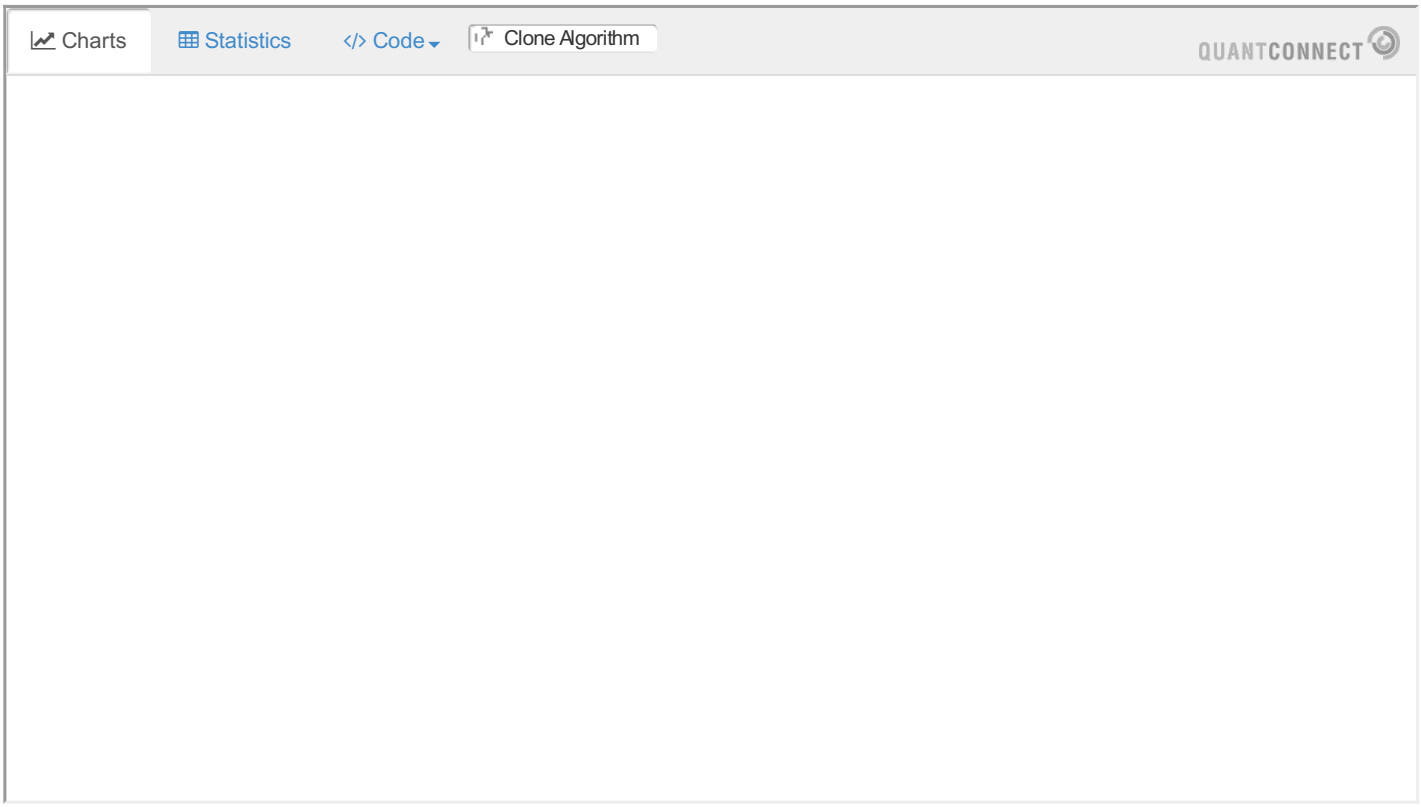
Example

The following backtest verifies the `ComboLimitOrder` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 16011SC00745000	16.50	1	Buy	Filled	16.50	
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.60	-1	Sell	Filled	-14.60	

On December 24, 2015 at 9:31 AM Eastern Time (ET), the algorithm places a combo limit order to buy one GOOG 16011SC00745000 contract and sell one GOOG 160115C00747500 contracts. The limit price is 75% of the contract spread, which equals 2.02. *The combo order doesn't fill immediately because the contract spread* 2.40 > 2.02. *By* 9:36 *AM*, *the spread drops to* 1.90, which is below the limit price, so the fill model fills the combo limit order.

To reproduce these results, backtest the following algorithm:



Order Types

Combo Leg Limit Orders

Introduction

Combo leg limit orders are individual orders that contain limit orders for muliple securities. Combo leg limit orders are different from combo limit orders because you can create combo leg limit orders without forcing each leg to have the same limit price. Combo leg limit orders currently only work for trading Option contracts.

Place Orders

To send a combo leg limit order, create multiple `Leg` objects to represent the legs of the combo order, then call the `ComboLegLimitOrder` method. The legs must each target a unique contract. At least one leg must have a positive quantity and at least one leg must have a negative quantity. If you don't have sufficient capital for the order, it's rejected.

```py
for canonical_symbol, chain in slice.OptionChains.items():
    # Select contracts
    contracts = [c for c in chain][:2]
    if len(contracts) < 2:
        return

    # Create order legs
    legs = []
    quantities = [1, -1]
    factors = [0.98, 1.02]
    for i, contract in enumerate(contracts):
        legs.append(Leg.Create(contract.Symbol, quantities[i], contract.LastPrice * factors[i]))

    # Place order
    self.ComboLegLimitOrder(legs, 1)
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `ComboLegLimitOrder` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity also sets the order direction of the combo limit order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `ComboLegLimitOrder` method.

```py
self.ComboLegLimitOrder(legs, quantity, tag=tag, orderProperties=order_properties)
```

Monitor Order Fills

Combo leg limit orders fill all the legs at the same time. Each leg can fill when the security price passes the limit price of the leg. To monitor the fills of your order, save a reference to the order tickets .

```
tickets = self.ComboLegLimitOrder(legs, 1)
for ticket in tickets:
    self.Debug(f"Symbol: {ticket.Symbol}; Quantity filled: {ticket.QuantityFilled}; Fill price:
{ticket.AverageFillPrice}")
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of the leg limit orders until the combo order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
# Create a new order and save the order tickets
tickets = self.ComboLegLimitOrder(legs, 1)

# Update the leg orders
for ticket in tickets:
    direction = np.sign(ticket.Quantity)
    update_settings = UpdateOrderFields()
    update_settings.Quantity = 2 * direction
    update_settings.LimitPrice = ticket.Get(OrderField.LimitPrice) + 0.01 * direction
    update_settings.Tag = f"Update #{len(ticket.UpdateRequests) + 1}"
    response = ticket.Update(update_settings)

    # Check if the update was successful
    if response.IsSuccess:
        self.Debug(f"Order updated successfully for {ticket.Symbol}")
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateTag`

```
response = ticket.UpdateLimitPrice(limitPrice, tag)

response = ticket.UpdateQuantity(quantity, tag)

response = ticket.UpdateTag(tag)
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
update_requests = ticket.UpdateRequests()
```

Cancel Orders

To cancel a combo leg limit order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it

from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
response = ticket.Cancel("Cancelled Trade")
if response.IsSuccess:
    self.Debug("Order successfully cancelled")
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `None` if the order hasn't been cancelled.

```
request = ticket.CancelOrderRequest()
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo leg limit orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for combo leg limit orders, see the **Orders** section of the brokerage model documentation .

Requirements

Combo leg limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Example

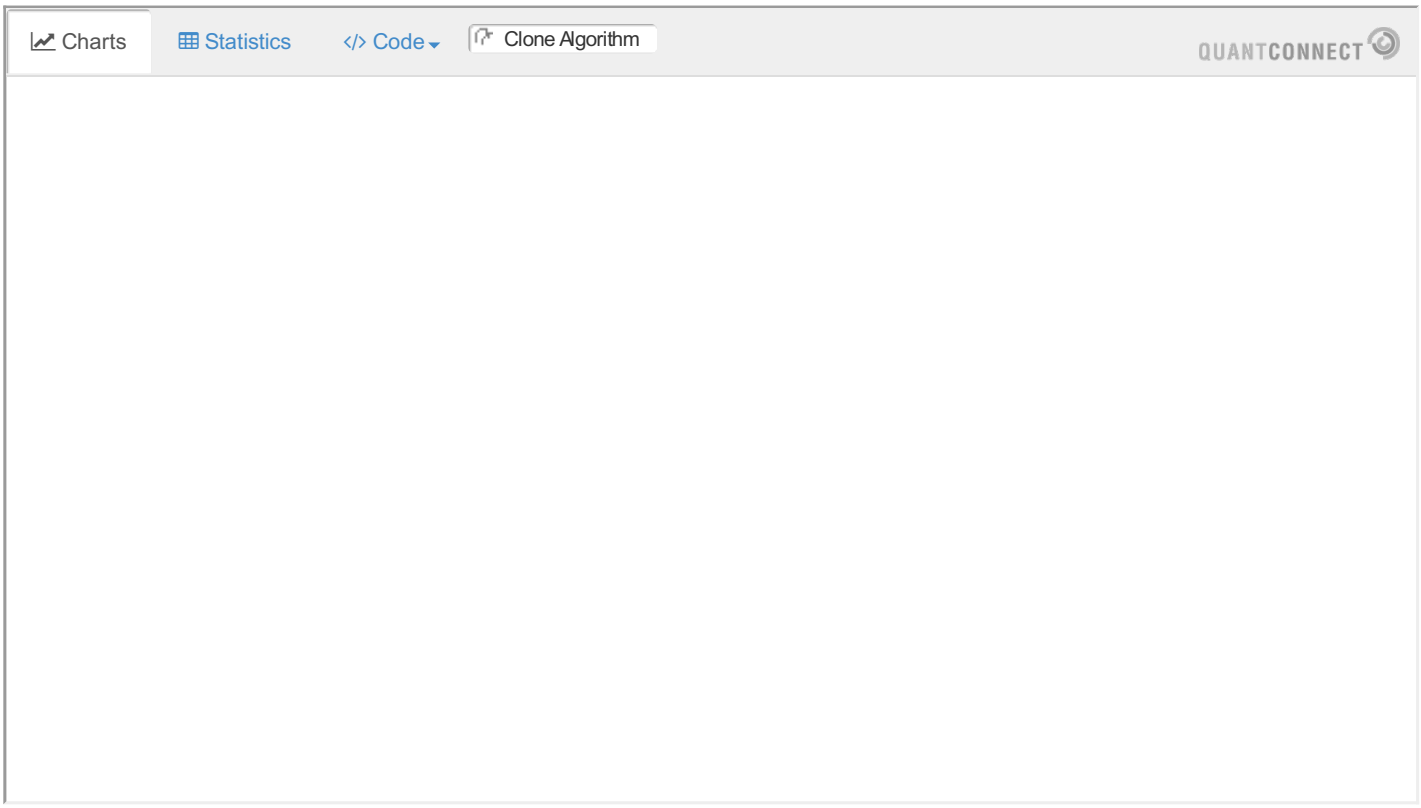
The following backtest verifies the `ComboLegLimitOrder` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 16011SC00745000	16.10	2	Buy	Filled	32.20	Update #72
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.11515	-2	Sell	Filled	-28.2303	Update #72

On December 24, 2015 at 9:31 AM Eastern Time (ET), the algorithm places a combo leg limit order to buy one GOOG 16011SC00745000 contract and sell two GOOG 160115C00747500 contracts. The limit price of both orders is 99.9% of the respective contract price, which is 16.2837*forGOOG*16011*SC*00745000*and*14.83515 for GOOG 160115C00747500. The combo order doesn't fill immediately, so the algorithm updates the leg orders at each time step. During the first

update, the algorithm sets the quantity of the GOOG 160115C00747500 leg to -2. During each update, the limit price moves 0.01 *closer to the market*. *That is*, *the limit price of GOOG* 16011 *SC* 00745000 *increases by* 0.01 and the limit price of GOOG 160115C00747500 decreases by $0.01. After the 72nd update, the ask low price is below the limit price of the leg to buy GOOG 16011SC00745000 and the bid high price is above the limit price of the leg to sell GOOG 160115C00747500, so the fill model fills the combo leg limit order at 10:44 AM ET.

To reproduce these results, backtest the following algorithm:



Order Types

Option Exercise Orders

Introduction

If you buy an Option contract, you can exercise your right to buy or sell the underlying asset at the strike price. However, you don't need to exercise it. You can sell the Option or let it expire worthless if it's out of the money. If you hold a long position in an Option that expires in the money, LEAN automatically exercises it at the expiration date. If you sell an Option contract and the buyer exercises their right to buy or sell the underlying asset, you are assigned the Option and must trade with the buyer at the strike price.

Place Orders

You can exercise American-style Option contracts anytime before they expire. Depending on your brokerage and the delivery method, you may be able to exercise European-style Option contracts on their expiration date. To exercise an Option, call the `ExerciseOption` method with the Option contract `Symbol` and a quantity. If you do not have sufficient capital for the order, it's rejected. By default, Option exercise orders are synchronous and fill immediately.

```
PY
ticket = self.ExerciseOption(contract_symbol, quantity)
```

You can provide a tag and order properties to the `ExerciseOption` method.

```
PY
self.ExerciseOption(symbol, quantity, tag=tag, orderProperties=order_properties)
```

Monitor Order Fills

To monitor the fills of your order, save a reference to the order ticket .

```
PY
ticket = self.ExerciseOption(contract_symbol, quantity)
self.Debug(f"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}")
```

For more information about how LEAN models Option exercise orders in backtests, see the Exercise Option model .

Synchronous Timeouts

Option exercise orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `Transactions.MarketOrderFillTimeout` property.

```
PY
 # Adjust the market fill-timeout to 30 seconds.
self.Transactions.MarketOrderFillTimeout = timedelta(seconds=30)
```

Place Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders, set the `asynchronous` argument to `True` .

```
ticket = self.ExerciseOption(contract_symbol, quantity, True)
```

Option Assignments

If you sell an Option in a backtest, LEAN can simulate an Option exercise order on behalf of the buyer. By default, LEAN scans your portfolio every hour. It considers exercising American-style Options if they are within 4 days of their expiration and it considers exercising European-style Options on their day of expiration. If you have sold an Option that's 5% in-the-money and the Option exercise order is profitable after the cost of fees, LEAN exercises the Option. For more information about how we simulate Option assignments, see the Assignment reality model.

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with Option exercise orders, set the brokerage model to a brokerage that supports them.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage)
```

To check if your brokerage has any special requirements for Option exercise orders, see the **Orders** section of the brokerage model documentation .

Requirements

Option exercise orders can only be submitted for option contracts with a long position. European-style options cannot be exercised before their expiration date.

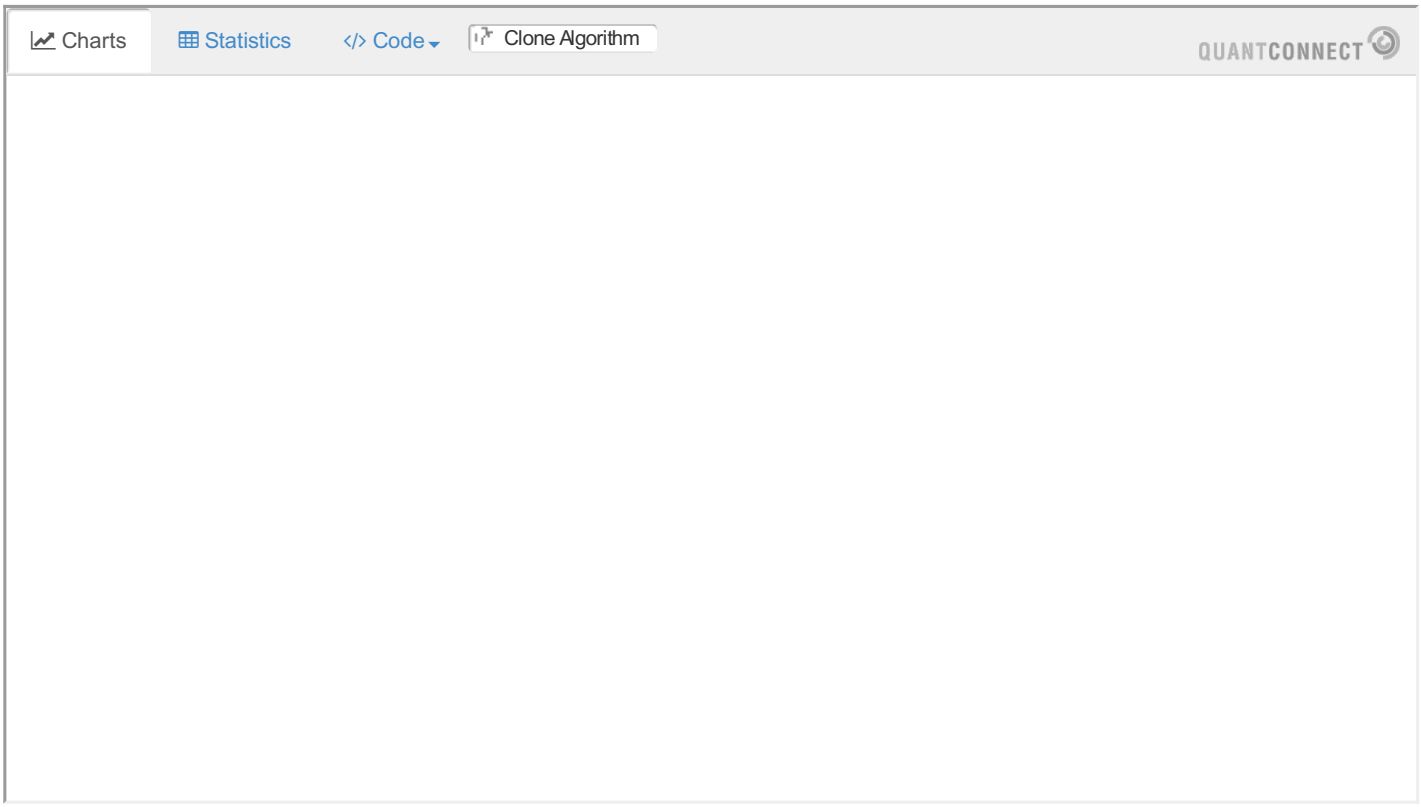
Example

The following backtest verifies the `ExerciseOption` behavior. The following table shows the first three trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	SPY 221216C00385000	345.30	1	Buy Market	Filled	34530.00	
2021-07-01T09:31:00Z	SPY 221216C00385000	0.00	-1	Sell Option Exercise	Filled	0.00	Automatic Exercise
2021-07-01T09:31:00Z	SPY	85.00	100	Sell Option Exercise	Filled	8500.00	Option Exercise

The algorithm first brought a deep ITM option based on the set option selection conditions by 345.30, *then exercise it actively*, *so* 100 *shares of SPY* (*in which* 1 *contract represents*) *was brought at its strike price at* 85.00, with the option discarded from the portfolio.

To reproduce these results, backtest the following algorithm:



Order Types

Other Order Types

Introduction

We are often asked to support other order types like one cancels the other, trailing stop, and multi-leg orders. Currently, LEAN doesn't support these order types, but we will add them over time. Part of the difficulty of implementing them is the incomplete brokerage support.

One Cancels the Other Orders

One cancels the other (OCO) orders are a set of orders that when one fills, it cancels the rest of the orders in the set. An example is to set a take-profit and a stop-loss order right after you enter a position. In this example, when either the take-profit or stop-loss order fills, you cancel the other order. OCO orders usually create an upper and lower bound on the exit price of a trade.

When you place OCO orders, their price levels are usually relative to the fill price of an entry trade. If your entry trade is a synchronous market order, you can immediately get the fill price from the order ticket. If your entry trade doesn't execute immediately, you can get the fill price in the OnOrderEvents event handler. Once you have the entry fill price, you can calculate the price levels for the OCO orders.

```py
# Get the fill price from the order ticket of a sync market order
self.ticket = self.MarketOrder("SPY", 1)
fill_price = self.ticket.AverageFillPrice

# Get the fill price from the OnOrderEvent event handler
def OnOrderEvent(self, orderEvent: OrderEvent) -> None:
    if orderEvent.Status == OrderStatus.Filled and self.ticket.OrderId == orderEvent.OrderId:
        fill_price = orderEvent.FillPrice
```

After you have the target price levels, to implement the OCO orders, you can place active orders or track the security price to simulate the orders.

Place Active Orders

To place active orders for the OCO orders, use a combination of limit orders and stop limit orders . Place these orders so that their price levels that are far enough apart from each other. If their price levels are too close, several of the orders can fill in a single time step. When one of the orders fills, in the `OnOrderEvent` event handler, cancel the other orders in the OCO order set.

```
self.stop_loss = None
self.take_profit = None

def OnOrderEvent(self, orderEvent: OrderEvent) -> None:
    if orderEvent.Status == OrderStatus.Filled:
        if orderEvent.OrderId == self.ticket.OrderId:
            self.stop_loss = self.StopMarketOrder(orderEvent.Symbol, -orderEvent.FillQuantity,
orderEvent.FillPrice*0.95)
            self.take_profit = self.LimitOrder(orderEvent.Symbol, -orderEvent.FillQuantity,
orderEvent.FillPrice*1.10)

        elif self.stop_loss is not None and orderEvent.OrderId == self.stop_loss.OrderId:
            self.take_profit.Cancel()

        elif self.take_profit is not None and orderEvent.OrderId == self.take_profit.OrderId:
            self.stop_loss.Cancel()
```

Simulate Orders

To simulate OCO orders, track the asset price in the `OnData` method and place market or limit orders when asset price reaches the take-profit or stop-loss level. The benefit of manually simulating the OCO orders is that both of the orders can't fill in the same time step.

```
def OnData(self, slice: Slice) -> None:
    if not self.Portfolio.Invested:
        ticket = self.MarketOrder("SPY", 1)
        self.entry_price = ticket.AverageFillPrice

    if slice.Bars.ContainsKey("SPY"):
        if slice.Bars["SPY"].Price >= self.entry_price * 1.10:
            self.Liquidate("SPY", -1, "take profit")

        elif slice.Bars["SPY"].Price <= self.entry_price * 0.95:
            self.Liquidate("SPY", -1, "stop loss")
```

Trailing Stop Loss Orders

A trailing stop loss order is a dynamic stop loss that moves towards the asset price as the asset trades away from the stop price. For example, if you set a trailing stop loss to 10%, the furthest away it will ever be from the asset price is 10%. If it's a sell trailing stop loss order that's below the asset price and the asset price increases such that the trailing stop is more than 10% away, the trailing stop loss moves up to be 10% below the asset price. If the asset price decreases, the trailing stop loss doesn't move.

To set a trailing stop loss order, see the Buy and Hold with a Trailing Stop Bootcamp lesson.

Multi-Leg Orders

Multi-leg orders are orders that contain multiple sub-orders. Examples of multi-leg orders include Option strategies like spreads , straddles , and strangles . You can manually implement other types of multi-leg orders with the built-in order types.

Trading and Orders

Position Sizing

Introduction

LEAN provides several methods to help you set specific portfolio weights for assets. These methods account for lot size and pre-calculated order fees.

Single Asset Targets

The `SetHoldings` method calculates the number of asset units to purchase based on the portfolio weight you provide and then submits market orders. This method provides a quick way to set up a portfolio with a set of weights for assets. If you already have holdings, you may want to liquidate the existing holdings first to free up buying power.

```py
 # Allocate 50% of buying power to IBM
self.SetHoldings("IBM", 0.5)

# Allocate 50% of portfolio value to IBM, but liquidate other holdings first
self.SetHoldings("IBM", 0.5, True)

# Provide a tag and order properties to the SetHoldings method
self.SetHoldings(symbol, weight, liquidate_existing_holdings, tag, order_properties)
```

If the percentage you provide translates to an order quantity of 0, the `SetHoldings` method doesn't place an order and doesn't log anything.

Multiple Asset Targets

When you trade a weighted basket of assets, sometimes you must intelligently scale down existing positions before increasing allocations to other assets. If you call the `SetHoldings` method with a list of `PortfolioTarget` objects, LEAN sorts the orders based on your position delta and then places the orders that reduce your position size in an asset before it places orders that increase your position size in an asset. When you call the `SetHoldings` method with a list of `PortfolioTarget` objects, the decimal you pass to the `PortfolioTarget` constructor represents the portfolio weight. In this situation, don't use the `PortfolioTarget.Percent` method.

```py
# Purchase a portfolio of targets, processing orders intelligently.
self.SetHoldings([PortfolioTarget("SPY", 0.8), PortfolioTarget("IBM", 0.2)])
```

Calculate Order Quantities

The `SetHoldings` method uses market order to reach the target portfolio weight you provide. If you want to use a different order type, you need to specify the quantity to trade. To calculate the number of units to trade based on a portfolio weight, call the `CalculateOrderQuantity` method. The method calculates the quantity based on the current price of the asset and adjusts it for the fee model of the security. The target weight you provide is an unleveraged value. For instance, if you have 2x leverage and request a 100% weight, the method calculates the quantity that uses

half of your available margin.

```py
 # Calculate the fee-adjusted quantity of shares with given buying power
quantity = self.CalculateOrderQuantity("IBM", 0.4)
```

Buying Power Buffer

If you place a market on open order near the market close, the market can gap overnight to a worse open price. If the gap is large enough against your trade direction, you may not have sufficient buying power at the open to fill your trade. To ensure a high probability of order fills through market gaps and discontinuities, the `SetHoldings` method assumes a 2.5% cash buffer. If LEAN rejects your orders due to buying power, widen the cash buffer through the algorithm `Settings` property.

```py
# Set the cash buffer to 5%
self.Settings.FreePortfolioValuePercentage = 0.05

# Set the cash buffer to $10,000
self.Settings.FreePortfolioValue = 10000
```

If you use `FreePortfolioValuePercentage` , you must set it in the `Initialize` or `PostInitialize` event handler. If you use `FreePortfolioValue` , you must set it after the `PostInitialize` event handler.

Trading and Orders

Liquidating Positions

Introduction

The `Liquidate` method lets you liquidate individual assets or your entire portfolio. The method creates market orders to close positions and returns the IDs of the liquidation orders. If you have pending open orders for the security when you call `Liquidate` , LEAN tries to cancel them. The `Liquidate` method works for all asset classes, except Crypto. To liquidate Crypto positions, see Crypto Trades .

Liquidate Individual Positions

To liquidate your holdings in an individual security, call the `Liquidate` method and provide a ticker or `Symbol` .

```
PY
# Liquidate all IBM in your portfolio
order_ids = self.Liquidate("IBM")
```

You can pass an order tag to the `Liquidate` method.

```
PY
self.Liquidate("AAPL", "Liquidated")
```

Liquidate All Positions

To liquidate all of the positions in your portfolio, call the `Liquidate` method without any ticker of `Symbol` arguments.

```
PY
// Liquidate your entire portfolio
order_ids = self.Liquidate()
```

You can pass an order tag to the `Liquidate` method.

```
PY
self.Liquidate(tag = "Liquidated")
```

Enable and Disable Liquidations

By default, the `Liquidate` method is functional. To enable and disable it, set the `Settings.LiquidateEnabled` property.

```
PY
# Disable liquidations
self.Settings.LiquidateEnabled = False

# Enable liquidations
self.Settings.LiquidateEnabled = True
```

Market Closed Considerations

If you liquidate your positions when the market is closed, LEAN converts the orders into market on open orders. If your brokerage doesn't support market on open orders , the order is invalid.

Trading and Orders

Crypto Trades

Introduction

All fiat and Crypto currencies are individual assets. When you buy a pair like BTCUSD, you trade USD for BTC. In this case, LEAN removes some USD from your portfolio cash book and adds some BTC. The virtual pair BTCUSD represents your position in the trade, but the virtual pair doesn't actually exist. It simply represents an open trade.

Place Trades

When you place Crypto trades, don't use the `CalculateOrderQuantity` or `SetHoldings` methods. Instead, calculate the order quantity based on the currency amounts in your cash book and place manual orders.

The following code snippet demonstrates how to allocate 90% of your portfolio to BTC.

```py
def OnData(self, data: Slice):
    self.set_crypto_holdings(self.symbol, .9)

def set_crypto_holdings(self, symbol, percentage):
    crypto = self.Securities[symbol]
    base_currency = crypto.BaseCurrency

    # Calculate the target quantity in the base currency
    target_quantity = percentage * (self.Portfolio.TotalPortfolioValue - self.Settings.FreePortfolioValue)
/ base_currency.ConversionRate
    quantity = target_quantity - base_currency.Amount

    # Round down to observe the lot size
    lot_size = crypto.SymbolProperties.LotSize
    quantity = round(quantity / lot_size) * lot_size

    if self.is_valid_order_size(crypto, quantity):
        self.MarketOrder(symbol, quantity)

# Brokerages have different order size rules
# Binance considers the minimum volume (price x quantity):
def is_valid_order_size(self, crypto, quantity):
    return abs(crypto.Price * quantity) > crypto.SymbolProperties.MinimumOrderSize
```

The preceding example doesn't take into account order fees. You can add a 0.1% buffer to accommodate it.

The following example demonstrates how to form an equal-weighted Crypto portfolio and stay within the cash buffer .

```py
def OnData(self, data: Slice):
    percentage = (1 - self.Settings.FreePortfolioValuePercentage) / len(self.symbols);
    for symbol in self.symbols:
        self.set_crypto_holdings(symbol, percentage)
```

You can replace the `self. Settings.FreePortfolioValuePercentage` for a class variable (e.g. `self.cash_buffer`).

When you place Crypto trades, ensure you have a sufficient balance of the base or quote currency before each trade. If you hold multiple assets and you want to put all of your capital into BTCUSD, you need to first convert all your non-

BTC assets into USD and then purchase BTCUSD.

For a full example of placing crypto trades, see the BasicTemplateCryptoAlgorithm .

Liquidate Positions

If you use the `Liquidate` method to liquidate a Crypto position, it only liquidates the quantity of the virtual pair. Since the virtual pair BTCUSD may not represent all of your BTC holdings, don't use the `Liquidate` method to liquidate Crypto positions. Instead, calculate the order quantity based on the currency amounts in your cash book and place manual orders. The following code snippet demonstrates how to liquidate a BTCUSD position.

```
PY
def OnData(self, data: Slice):
    self.liquidate_crypto(self.symbol)

def liquidate_crypto(self, symbol):
    crypto = self.Securities[symbol]
    base_currency = crypto.BaseCurrency

    # Avoid negative amount after liquidate
    quantity = min(crypto.Holdings.Quantity, base_currency.Amount)

    # Round down to observe the lot size
    lot_size = crypto.SymbolProperties.LotSize;
    quantity = (round(quantity / lot_size) - 1) * lot_size

    if self.IsValidOrderSize(crypto, quantity):
        self.MarketOrder(symbol, -quantity)
```

The order fees don't respect the lot size. When you try to liquidate a position, the absolute value of the base currency quantity can be less than the lot size and greater than zero. In this case, your algorithm holds a position that you can't liquidate and `self. Portfolio[symbol].Invested` is `True` . The following code snippet demonstrates how to determine if you can liquidate a position:

```
PY
def OnData(self, data: Slice):
    crypto = self.Securities[self.symbol]
    if abs(crypto.Holdings.Quantity) > crypto.SymbolProperties.LotSize:
        self.liquidate_crypto(self.symbol)
```

Bear Call Spread

Introduction

Bear call spread , also known as **short call spread** , consists of selling an ITM call and buying an OTM call. Both calls have the same underlying Equity and the same expiration date. The ITM call serves as a hedge for the OTM call. The bear call spread profits from a drop in underlying asset price.

Implementation

Follow these steps to implement the bear call spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
PY
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 3, 5)
    self.SetCash(500000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(self.UniverseFunc)

def UniverseFunc(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return universe.IncludeWeeklys().Strikes(-15, 15).Expiration(timedelta(0), timedelta(31))
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Get the furthest expiry date of the contracts
    expiry = sorted(chain, key = lambda x: x.Expiry, reverse=True)[0].Expiry

    # Select the call Option contracts with the furthest expiry
    calls = [i for i in chain if i.Expiry == expiry and i.Right == OptionRight.Call]
    if len(calls) == 0: return

    # Select the ITM and OTM contract strike prices from the remaining contracts
    call_strikes = sorted([x.Strike for x in calls])
    itm_strike = call_strikes[0]
    otm_strike = call_strikes[-1]
```

3. In the `OnData` method, call the `OptionStrategies.BearCallSpread` method and then submit the order.

```
PY
option_strategy = OptionStrategies.BearCallSpread(self.symbol, itm_strike, otm_strike, expiry)
self.Buy(option_strategy, 1)
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

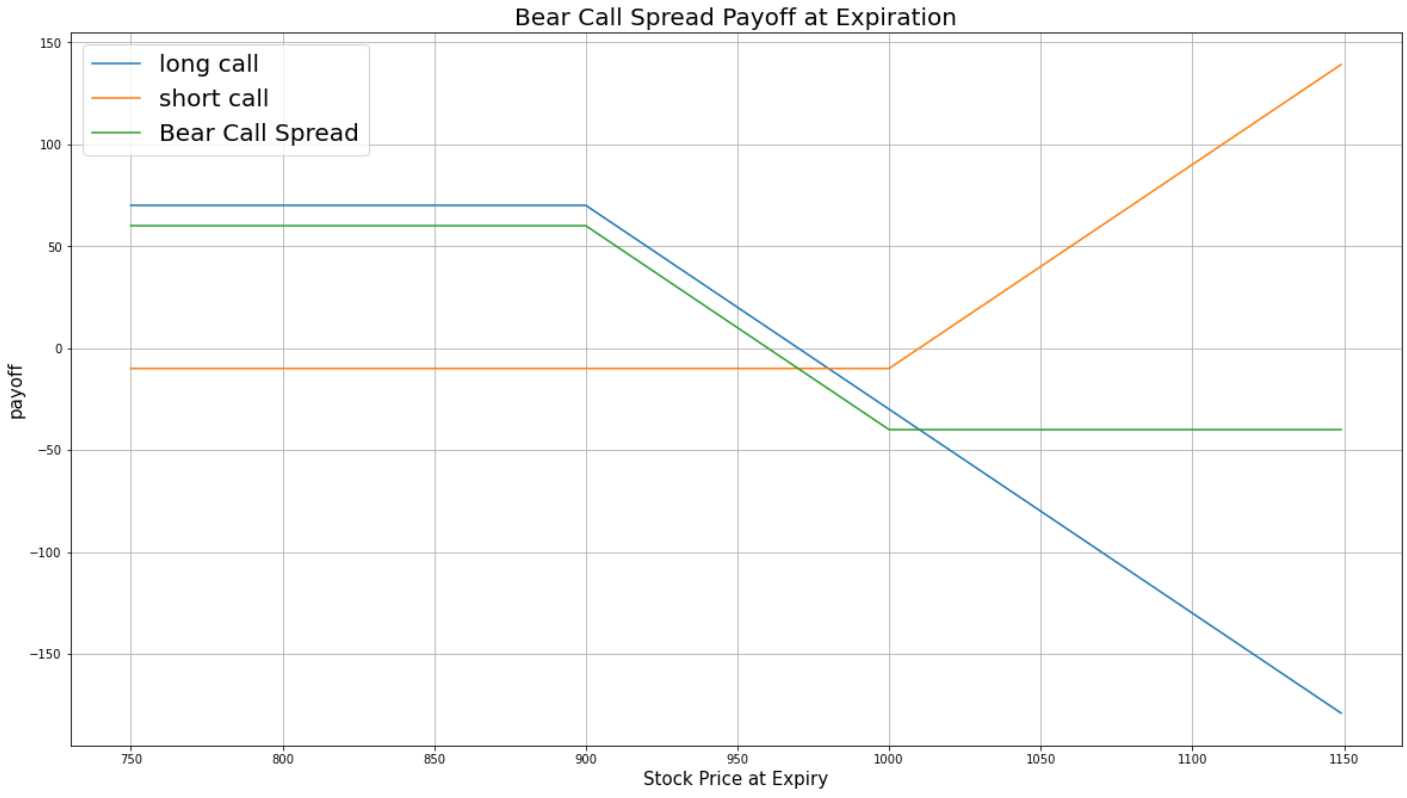
The bear call spread is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
P_T &= (C_T^{OTM} - C_T^{ITM} + C_0^{ITM} - C_0^{OTM}) \times m - fee
\end{aligned}
$$

where

C_T^{OTM}	=	OTM call value at time T
C_T^{ITM}	=	ITM call value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM call strike price
K^{ITM}	=	ITM call strike price
P_T	=	Payout total at time T
C_0^{ITM}	=	ITM call value at position opening (debit paid)
C_0^{OTM}	=	OTM call value at position opening (credit received)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is the net credit you receive from opening the trade, $C_0^{ITM} - C_0^{OTM}$. If the price declines, both calls

expire worthless.

The maximum loss is $K^{OTM} - K^{ITM} + C_0^{ITM} - C_0^{OTM}$, which occurs when the underlying price is above the strike prices of both call Option contracts.

If the Option is American Option, there is a risk of early assignment on the sold contract.

Example

The following table shows the price details of the assets in the algorithm:

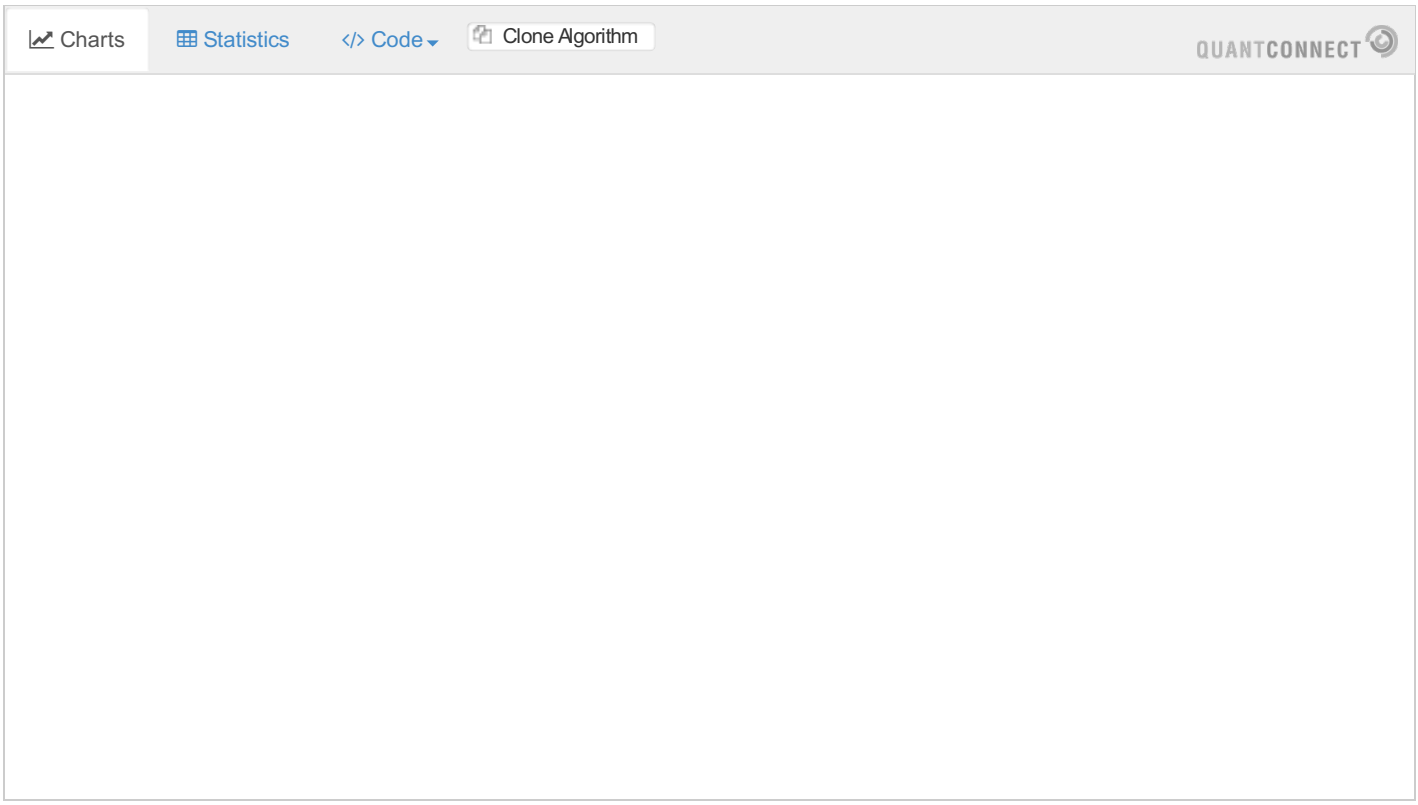
Asset	Price ($)	Strike ($)
OTM call	4.40	835.00
ITM call	36.80	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{aligned} C_T^{OTM} &= (S_T - K^{OTM})^+ \\ &= (829.08 - 835.00)^+ \\ &= 0 \\ C_T^{ITM} &= (S_T - K^{ITM})^+ \\ &= (829.08 - 767.50)^+ \\ &= 61.58 \\ P_T &= (C_T^{OTM} - C_T^{ITM} + C_0^{ITM} - C_0^{OTM}) \times m - fee \\ &= (0 - 61.58 + 36.80 - 4.40) \times 100 - 1.00 \times 2 \\ &= -2920 \end{aligned}$$

So, the strategy losses $2,920.

The following algorithm implements a bear call spread Option strategy:



Demonstration Algorithm
IndexOptionBearCallSpreadAlgorithm.py Python

Option Strategies

Bear Put Spread

Introduction

Bear put spread , also known as **short put spread** , consists of buying an ITM put and selling an OTM put. Both puts have the same underlying Equity and the same expiration date. The OTM put serves as a hedge for the ITM put. The bear put spread profits from a decline in underlying asset price.

Implementation

Follow these steps to implement the bear put spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 3, 5)
    self.SetCash(500000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(self.UniverseFunc)

def UniverseFunc(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return universe.IncludeWeeklys().Strikes(-15, 15).Expiration(timedelta(0), timedelta(31))
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Get the furthest expiry date of the contracts
    expiry = sorted(chain, key = lambda x: x.Expiry, reverse=True)[0].Expiry

    # Select the put Option contracts with the furthest expiry
    puts = [i for i in chain if i.Expiry == expiry and i.Right == OptionRight.Put]
    if len(puts) == 0: return

    # Select the ITM and OTM contract strike prices from the remaining contracts
    put_strikes = sorted([x.Strike for x in puts])
    otm_strike = put_strikes[0]
    itm_strike = put_strikes[-1]
```

3. In the `OnData` method, call the `OptionStrategies.BearPutSpread` method and then submit the order.

```
option_strategy = OptionStrategies.BearPutSpread(self.symbol, itm_strike, otm_strike, expiry)
self.Buy(option_strategy, 1)
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

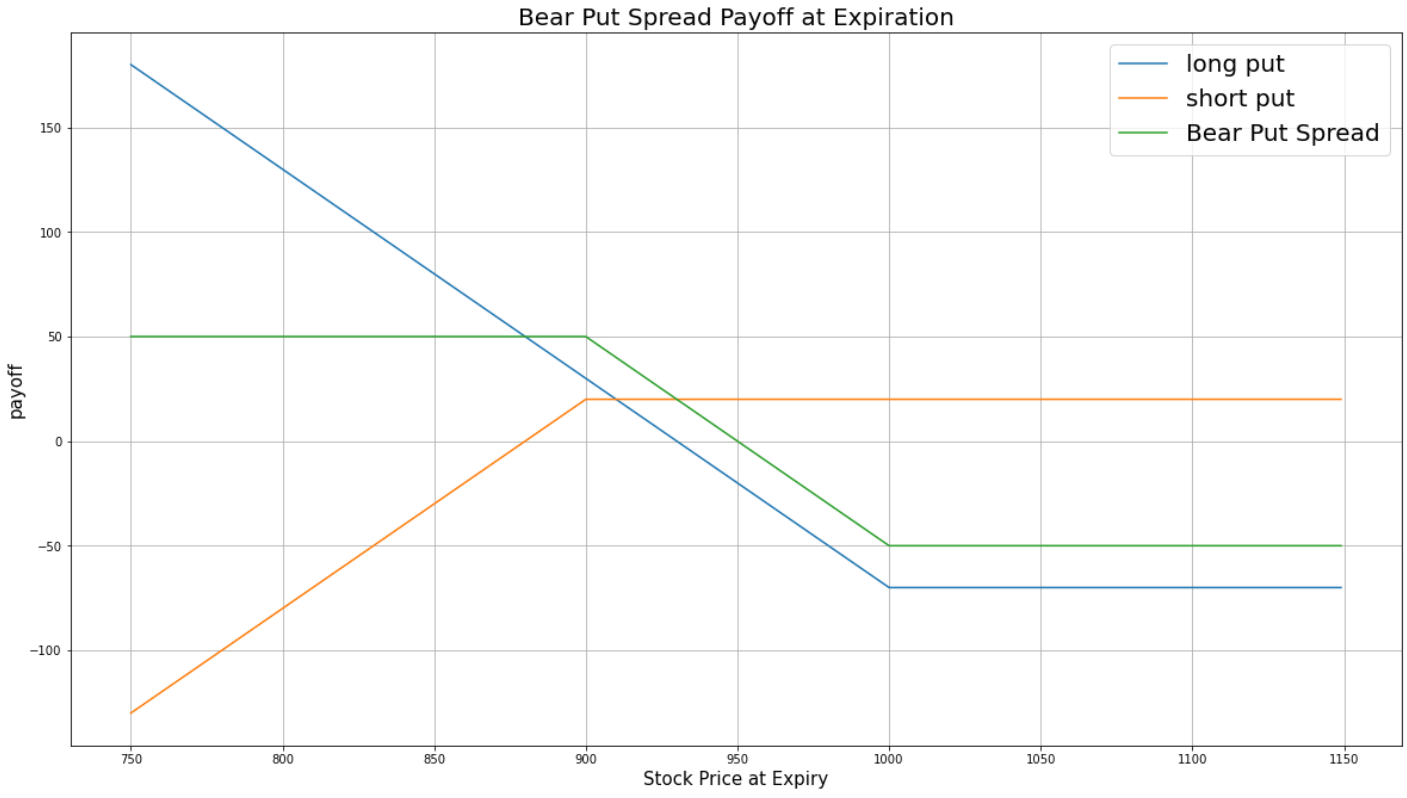
The bear put spread is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
P_T &= (P_T^{ITM} - P_T^{OTM} + P_0^{OTM} - P_0^{ITM}) \times m - fee
\end{aligned}
$$

where

P_T^{OTM}	=	OTM put value at time T
P_T^{ITM}	=	ITM put value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM put strike price
K^{ITM}	=	ITM put strike price
P_T	=	Payout total at time T
P_0^{ITM}	=	ITM put value at position opening (debit paid)
P_0^{OTM}	=	OTM put value at position opening (credit received)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is $K^{ITM} - K^{OTM} + P_0^{OTM} - P_0^{ITM}$. If the underlying price is below than the strike prices of both put

Option contracts, they are worth $(K - S_T)$ at expiration.

The maximum loss is the net debit you paid to open the position, $P_0^{OTM} - P_0^{ITM}$.

If the Option is American Option, there is a risk of early assignment on the sold contract.

Example

The following table shows the price details of the assets in the algorithm:

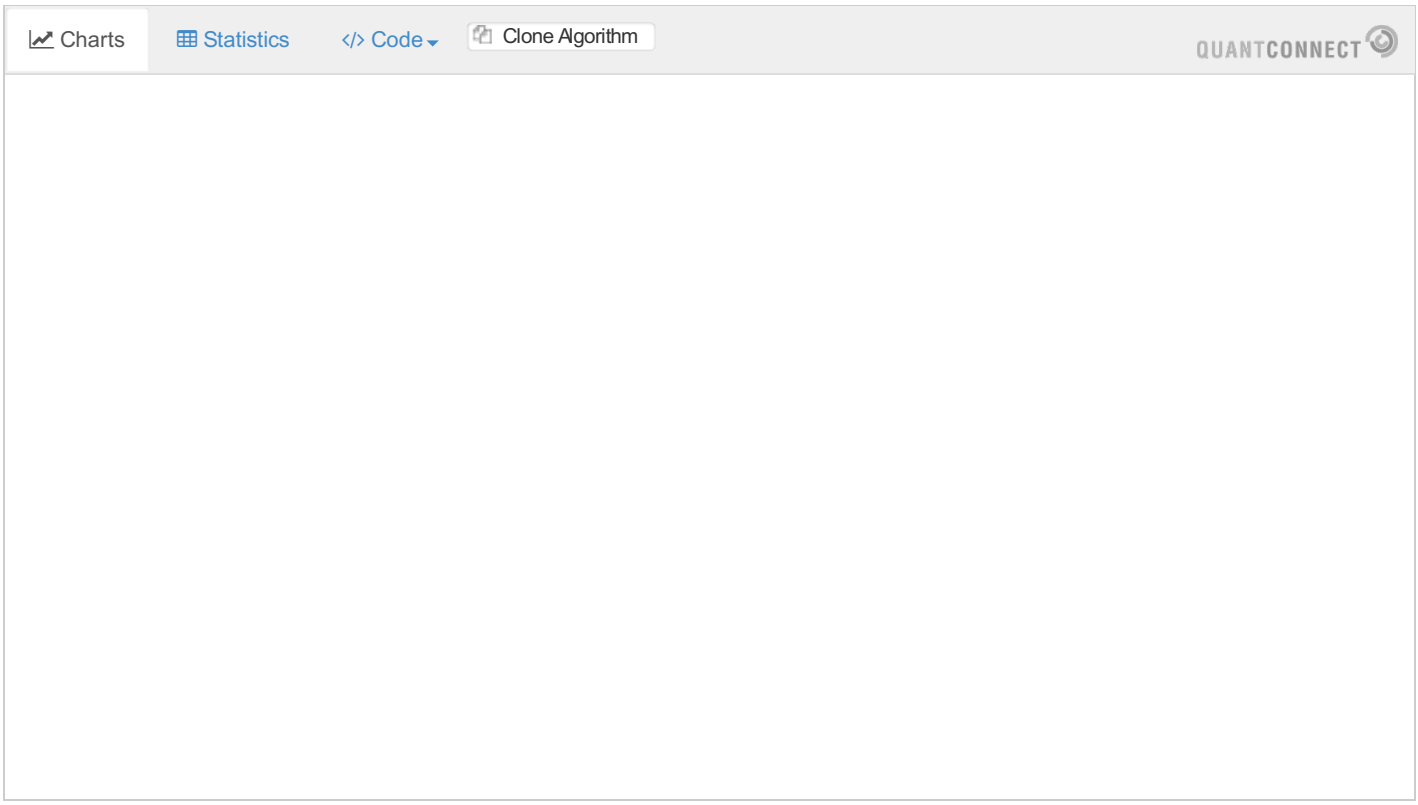
Asset	**Price ($)**	**Strike ($)**
OTM put	4.60	767.50
ITM put	40.00	835.00
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
&= (767.50 - 829.08)^+ \\
&= 0 \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
&= (835.00 - 829.08)^+ \\
&= 5.92 \\
P_T &= (P_T^{ITM} - P_T^{OTM} + P_0^{OTM} - P_0^{ITM}) \times m - fee \\
&= (5.92 - 0 + 4.60 - 40.00) \times 100 - 1.00 \times 2 \\
&= -2950
\end{aligned}
$$

So, the strategy losses $2,950.

The following algorithm implements a bear put spread strategy:



Demonstration Algorithm
IndexOptionBearPutSpreadAlgorithm.py Python

Option Strategies

Bull Call Spread

Introduction

Bull call spread , also known as **long call spread** , consists of buying an ITM call and selling an OTM call. Both calls have the same underlying Equity and the same expiration date. The OTM call serves as a hedge for the ITM call. The bull call spread profits from a rise in underlying asset price.

Implementation

Follow these steps to implement the bull call spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
PY
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 3, 5)
    self.SetCash(500000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(self.UniverseFunc)

def UniverseFunc(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return universe.IncludeWeeklys().Strikes(-15, 15).Expiration(timedelta(0), timedelta(31))
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Get the furthest expiration date of the contracts
    expiry = sorted(chain, key = lambda x: x.Expiry, reverse=True)[0].Expiry

    # Select the call Option contracts with the furthest expiry
    calls = [i for i in chain if i.Expiry == expiry and i.Right == OptionRight.Call]
    if len(calls) == 0: return

    # Select the ITM and OTM contract strike prices from the remaining contracts
    call_strikes = sorted([x.Strike for x in calls])
    itm_strike = call_strikes[0]
    otm_strike = call_strikes[-1]
```

3. In the `OnData` method, call the `OptionStrategies.BullCallSpread` method and then submit the order.

```
PY
option_strategy = OptionStrategies.BullCallSpread(self.symbol, itm_strike, otm_strike, expiry)
self.Buy(option_strategy, 1)
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

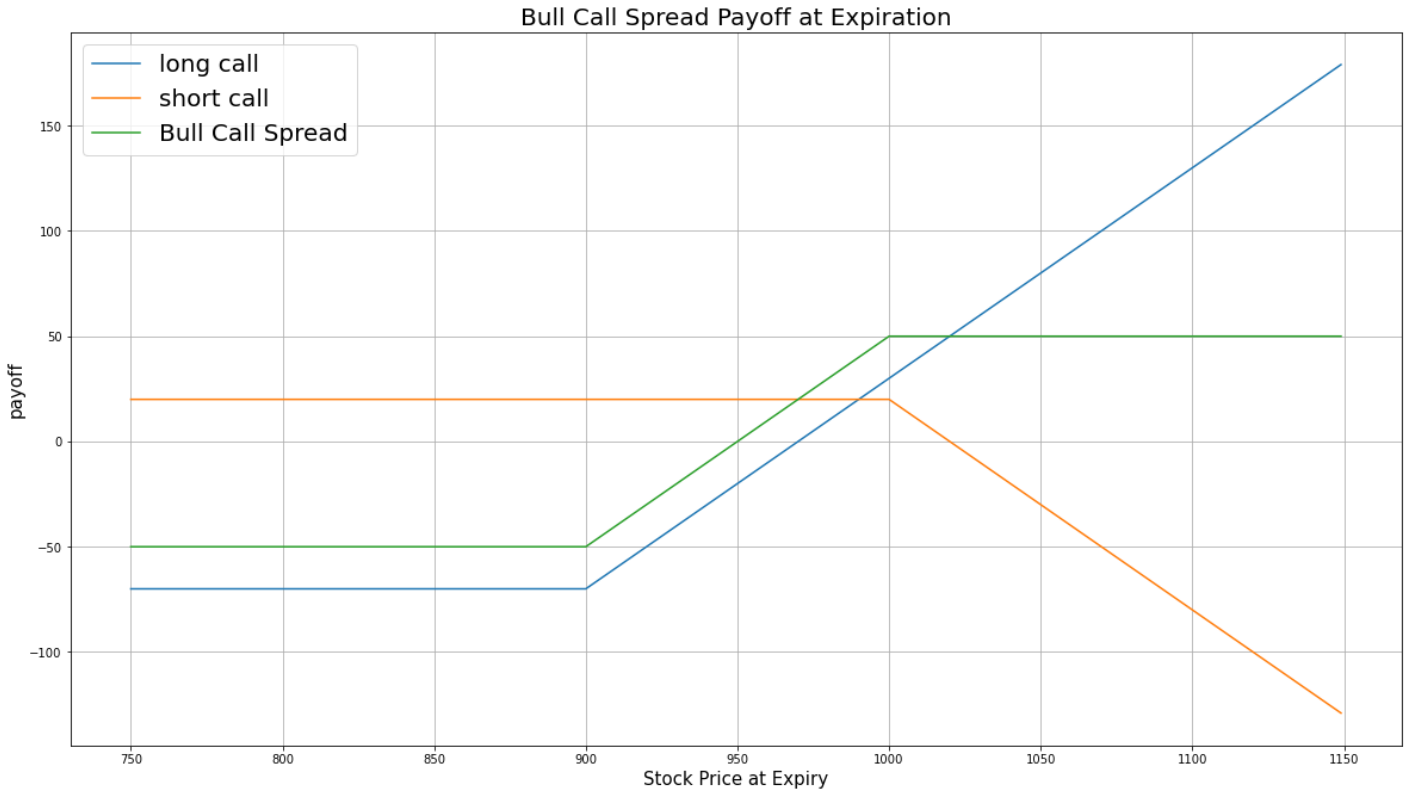
The bull call spread is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
P_T &= (C_T^{ITM} - C_T^{OTM} + C_0^{OTM} - C_0^{ITM}) \times m - fee
\end{aligned}
$$

where

C_T^{OTM}	=	OTM call value at time T
C_T^{ITM}	=	ITM call value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM call strike price
K^{ITM}	=	ITM call strike price
P_T	=	Payout total at time T
C_0^{ITM}	=	ITM call value at position opening (debit paid)
C_0^{OTM}	=	OTM call value at position opening (credit received)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is $K^{OTM} - K^{ITM} + C_0^{OTM} - C_0^{ITM}$. If the underlying price increases to exceed both strikes at expiration,

both calls are worth ($S_T - K$) at expiration.

The maximum loss is the net debit you paid to open the position, $C_0^{OTM} - C_0^{ITM}$.

If the Option is American Option, there is a risk of early assignment on the sold contract.

Example

The following table shows the price details of the assets in the algorithm:

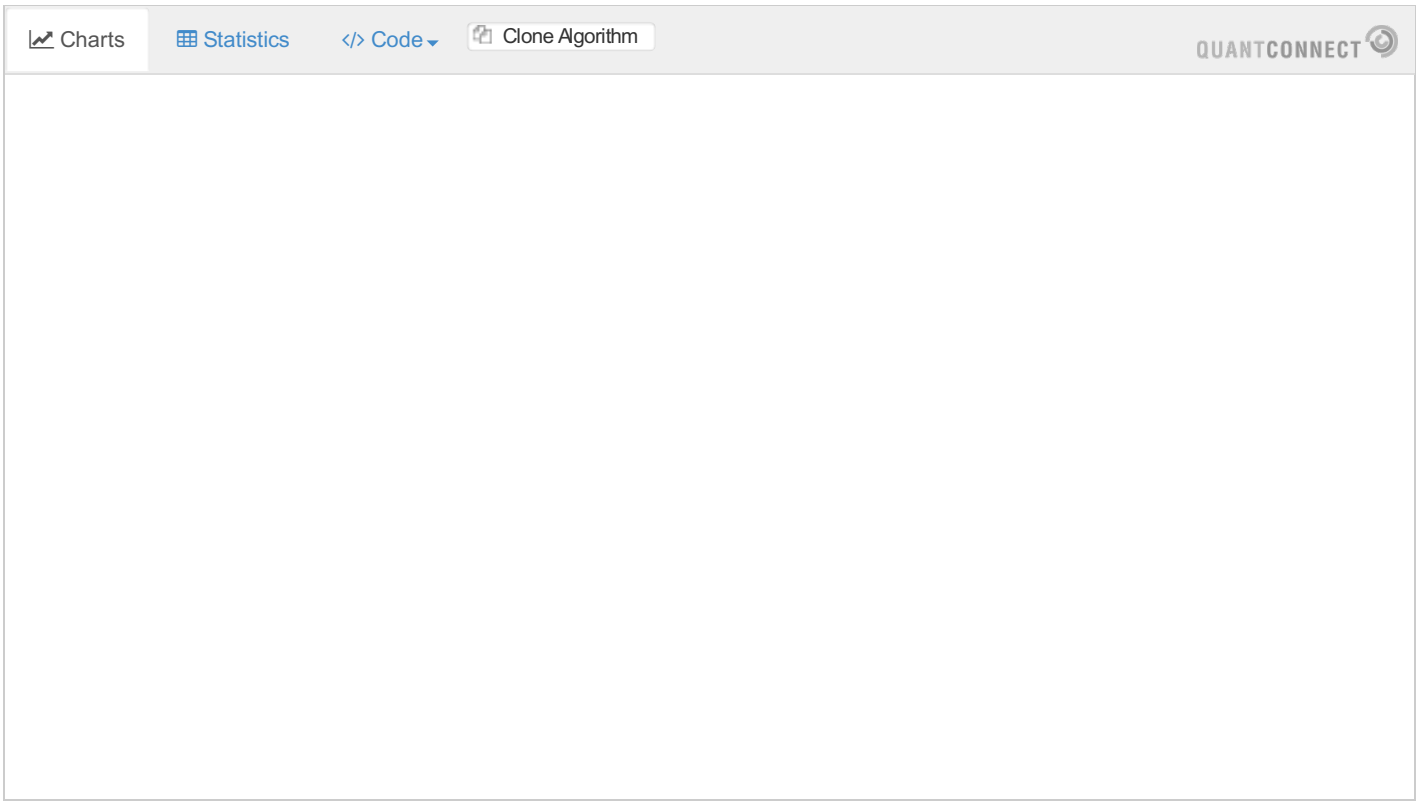
Asset	**Price ($)**	**Strike ($)**
OTM call	3.00	835.00
ITM call	41.00	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
&= (829.08 - 835.00)^+ \\
&= 0 \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
&= (829.08 - 767.50)^+ \\
&= 61.58 \\
P_T &= (C_T^{ITM} - C_T^{OTM} + C_0^{OTM} - C_0^{ITM}) \times m - fee \\
&= (61.58 - 0 + 3.00 - 41.00) \times 100 - 1.00 \times 2 \\
&= 2356
\end{aligned}
$$

So, the strategy profits $2,356.

The following algorithm implements a bull call spread strategy:



Demonstration Algorithm
IndexOptionBullCallSpreadAlgorithm.py Python

Option Strategies

Bull Put Spread

Introduction

Bull put spread , also known as **long put spread** , consists of buying an OTM put and selling an ITM put. Both puts have the same underlying Equity and the same expiration date. The OTM put serves as a hedge for the ITM put. The bull put spread profits from a rise in underlying asset price.

Implementation

Follow these steps to implement the bull put spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
PY
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 3, 5)
    self.SetCash(500000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(self.UniverseFunc)

def UniverseFunc(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return universe.IncludeWeeklys().Strikes(-15, 15).Expiration(timedelta(0), timedelta(31))
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Get the furthest expiration date of the contracts
    expiry = sorted(chain, key = lambda x: x.Expiry, reverse=True)[0].Expiry

    # Select the put Option contracts with the furthest expiry
    puts = [i for i in chain if i.Expiry == expiry and i.Right == OptionRight.Put]
    if len(puts) == 0: return

    # Select the ITM and OTM contract strikes from the remaining contracts
    put_strikes = sorted([x.Strike for x in puts])
    otm_strike = put_strikes[0]
    itm_strike = put_strikes[-1]
```

3. In the `OnData` method, call the `OptionStrategies.BullPutSpread` method and then submit the order.

```
PY
option_strategy = OptionStrategies.BullPutSpread(self.symbol, itm_strike, otm_strike, expiry)
self.Buy(option_strategy, 1)
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

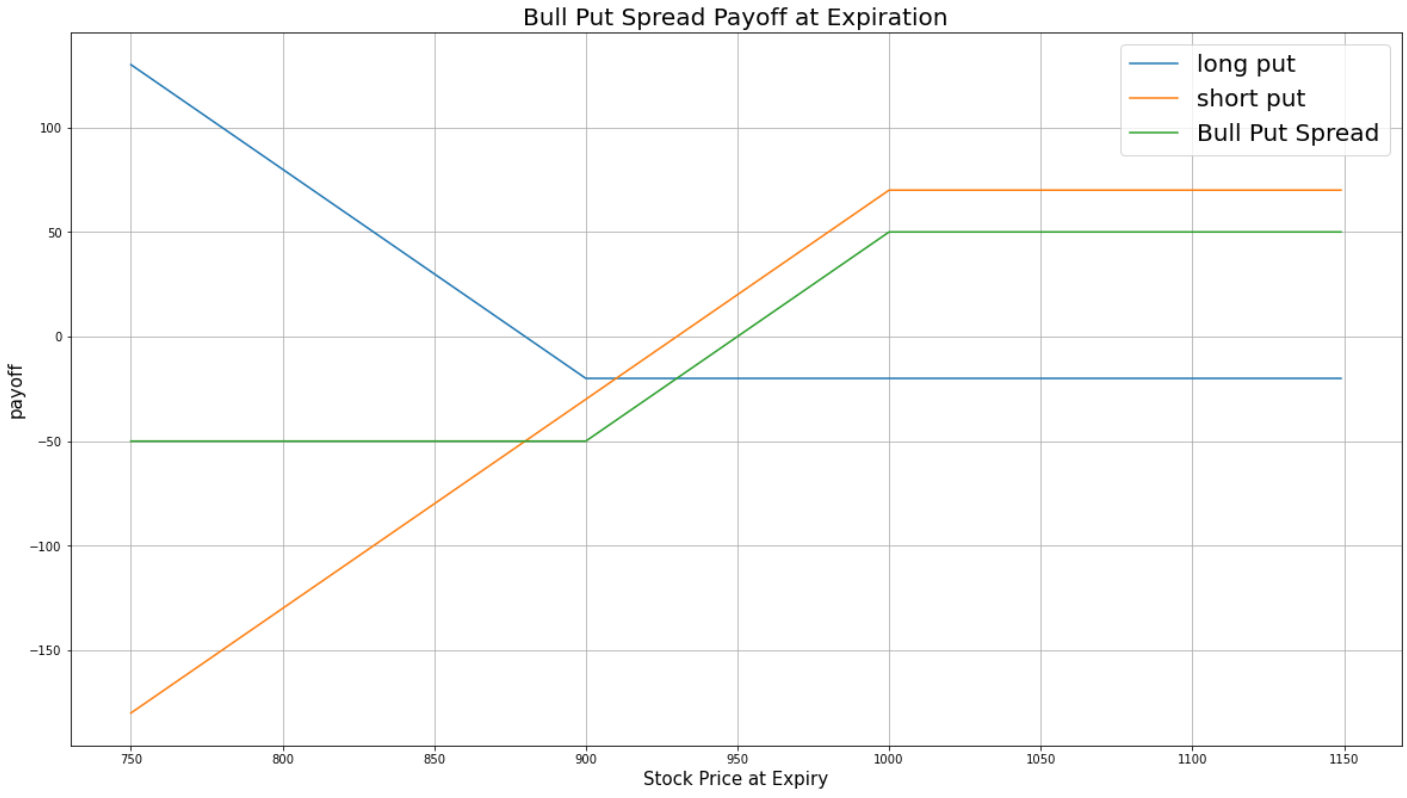
This is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
P_T &= (P_T^{OTM} - P_T^{ITM} + P_0^{ITM} - P_0^{OTM}) \times m - fee
\end{aligned}
$$

where

P_T^{OTM}	=	OTM put value at time T
P_T^{ITM}	=	ITM put value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM put strike price
K^{ITM}	=	ITM put strike price
P_T	=	Payout total at time T
P_0^{ITM}	=	ITM put value at position opening (credit received)
P_0^{OTM}	=	OTM put value at position opening (debit paid)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is the net credit you received when opening the position, $P_0^{ITM} - P_0^{OTM}$. If the underlying price is

higher than the strike prices of both put contracts at expiration, both puts expire worthless.

The maximum loss is $K^{ITM} - K^{OTM} + P_0^{ITM} - P_0^{OTM}$.

If the Option is American Option, there is a risk of early assignment on the sold contract.

Example

The following table shows the price details of the assets in the algorithm:

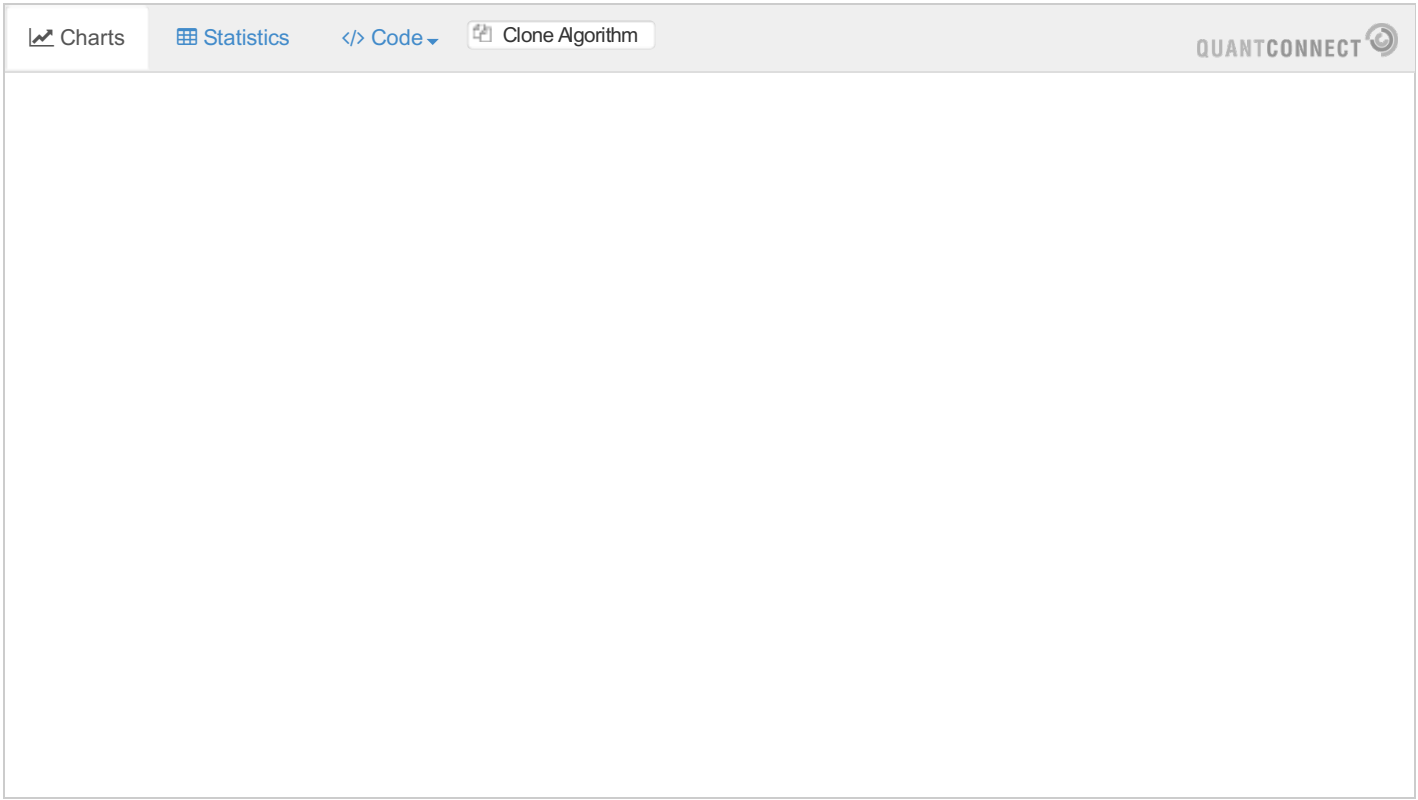
Asset	Price ($)	Strike ($)
OTM put	5.70	767.50
ITM put	35.50	835.00
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ & = & (767.50-829.08)^{+}\\ & = & 0\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ & = & (835.00-829.08)^{+}\\ & = & 5.92\\ P_T & = & (P^{OTM}_T - P^{ITM}_T + P^{ITM}_0 - P^{OTM}_0)\times m - fee\\ & = & (0-5.92+35.50-5.70)\times100-1.00\times2\\ & = & 2386\\ \end{array}$$

So, the strategy profits $2,386.

The following algorithm implements a bull put spread strategy:



Demonstration Algorithm
IndexOptionBullPutSpreadAlgorithm.py Python

Option Strategies

Call Butterfly

Introduction

The **call butterfly** strategy is the combination of a bull call spread and a bear call spread . In the call butterfly, all of the calls should have the same underlying Equity, the same expiration date, and the same strike price distance between the ITM-ATM and OTM-ATM call pairs. The call butterfly can be long or short.

Long Call Butterfly

The long call butterfly consists of a long ITM call, a long OTM call, and 2 short ATM calls. This strategy profits from low volatility in the underlying Equity price.

Short Call Butterfly

The short call butterfly consists of a short ITM call, a short OTM call, and 2 long ATM calls. This strategy profits from high volatility in the underlying Equity price.

Implementation

Follow these steps to implement the call butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 3, 5)
    self.SetCash(500000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(self.UniverseFunc)

def UniverseFunc(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return universe.IncludeWeeklys().Strikes(-15, 15).Expiration(timedelta(0), timedelta(31))
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Get the furthest expiry date of the contracts
    expiry = sorted(chain, key = lambda x: x.Expiry, reverse=True)[0].Expiry

    # Select the call Option contracts with the furthest expiry
    calls = [i for i in chain if i.Expiry == expiry and i.Right == OptionRight.Call]
    if len(calls) == 0: return

    # Get the strike prices of the all the call Option contracts
    call_strikes = sorted([x.Strike for x in calls])

    # Get the ATM strike price
    atm_strike = sorted(calls, key=lambda x: abs(x.Strike - chain.Underlying.Price))[0].Strike

    # Get the strike prices for the contracts not ATM
    spread = min(abs(call_strikes[0] - atm_strike), abs(call_strikes[-1] - atm_strike))
    itm_strike = atm_strike - spread
    otm_strike = atm_strike + spread
```

3. In the `OnData` method, call the `OptionStrategies.CallButterfly` method and then submit the order.

```
option_strategy = OptionStrategies.CallButterfly(self.symbol, otm_strike, atm_strike, itm_strike,
expiry)
self.Buy(option_strategy, 1)    # if long call butterfly
self.Sell(option_strategy, 1)   # if short call butterfly
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` and `Sell` methods.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
self.Sell(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

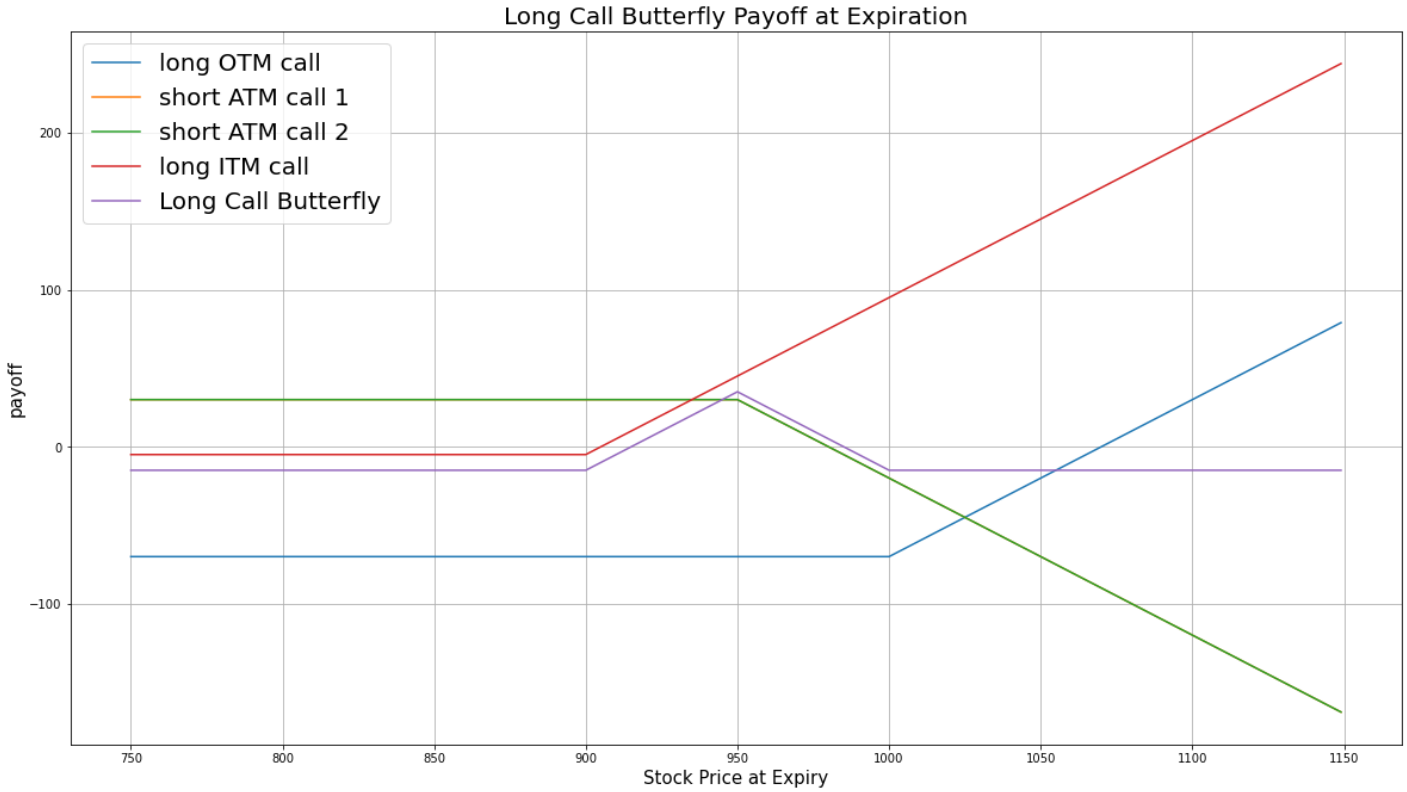
The call butterfly can be long or short.

Long Call Butterfly

The long call butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ C^{ATM}_T & = & (S_T - K^{ATM})^{+}\\ P_T & = & (C^{OTM}_T + C^{ITM}_T - 2\times C^{ATM}_T + 2\times C^{ATM}_0 - C^{ITM}_0 - C^{OTM}_0)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ITM}_T & = & \textrm{ITM call value at time T}\\ & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM call strike price}\\ & K^{ITM} & = & \textrm{ITM call strike price}\\ & K^{ATM} & = & \textrm{ATM call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ITM}_0 & = & \textrm{ITM call value at position opening (debit paid)}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ & C^{ATM}_0 & = & \textrm{OTM call value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K^{ATM} - K^{ITM} + 2\times C^{ATM}_0 - C^{ITM}_0 - C^{OTM}_0$. It occurs when the underlying price is the same price at expiration as it was when opening the position and the payouts of the bull and bear call spreads are at their maximum.

The maximum loss is the net debit paid: $2\times C^{ATM}_0 - C^{ITM}_0 - C^{OTM}_0$. It occurs when the underlying price is less than ITM strike or greater than OTM strike at expiration.

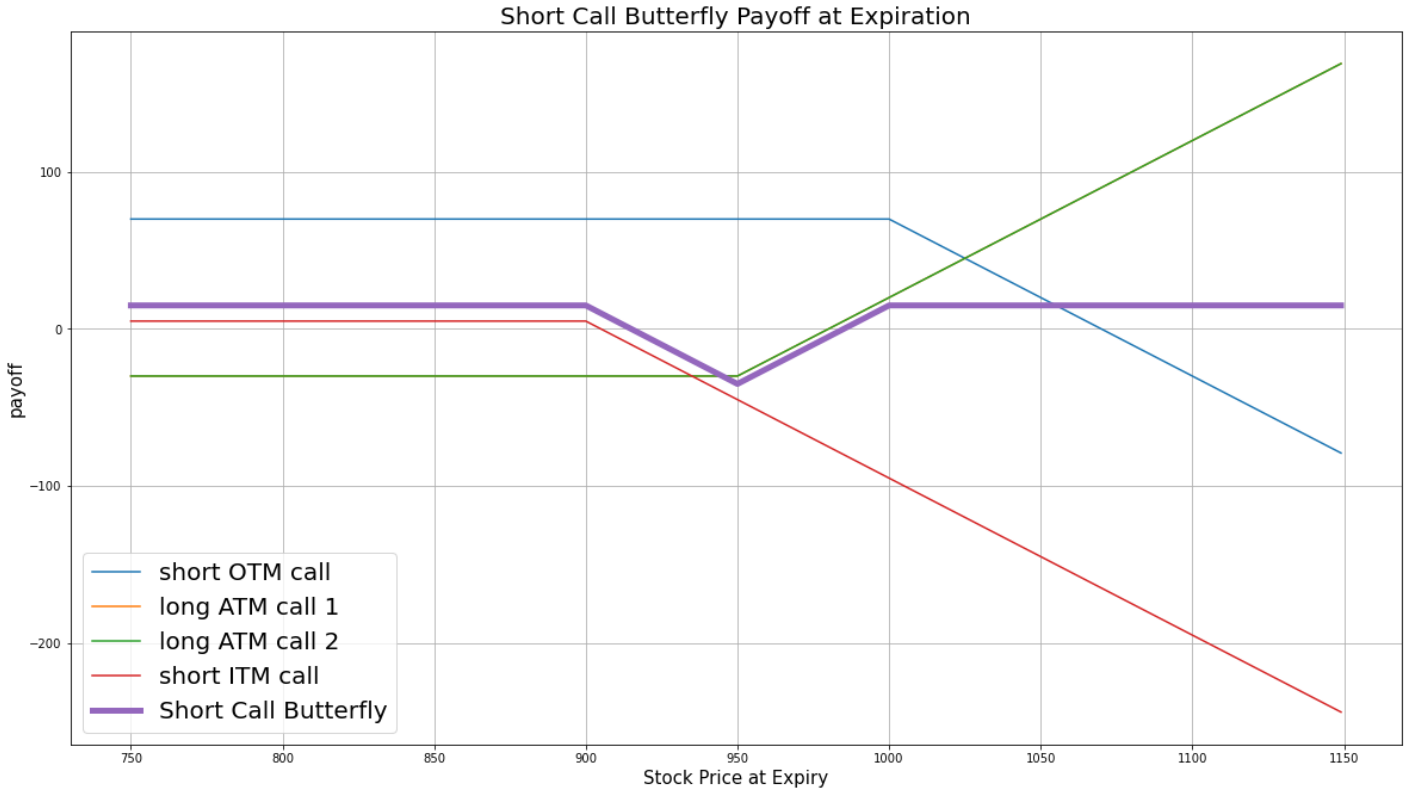
If the Option is an American Option, there is a risk of early assignment on the sold contracts.

Short Call Butterfly

The short call butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ C^{ATM}_T & = & (S_T - K^{ATM})^{+}\\ P_T & = & (2\times C^{ATM}_T - C^{OTM}_T - C^{ITM}_T - 2\times C^{ATM}_0 + C^{ITM}_0 + C^{OTM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ITM}_T & = & \textrm{ITM call value at time T}\\ & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM call strike price}\\ & K^{ITM} & = & \textrm{ITM call strike price}\\ & K^{ATM} & = & \textrm{ATM call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ITM}_0 & = & \textrm{ITM call value at position opening (credit received)}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (credit received)}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is the net credit received: $C^{ITM}_0 + C^{OTM}_0 - 2\times C^{ATM}_0$. It occurs when the underlying price is less than ITM strike or greater than OTM strike at expiration.

The maximum loss is $K^{ATM} - K^{ITM} + C^{ITM}_0 + C^{OTM}_0 - 2\times C^{ATM}_0$. It occurs when the underlying price is at the same level as when you opened the trade.

If the Option is an American Option, there is a risk of early assignment on the sold contracts.

Example

The following table shows the price details of the assets in the long version of the algorithm:

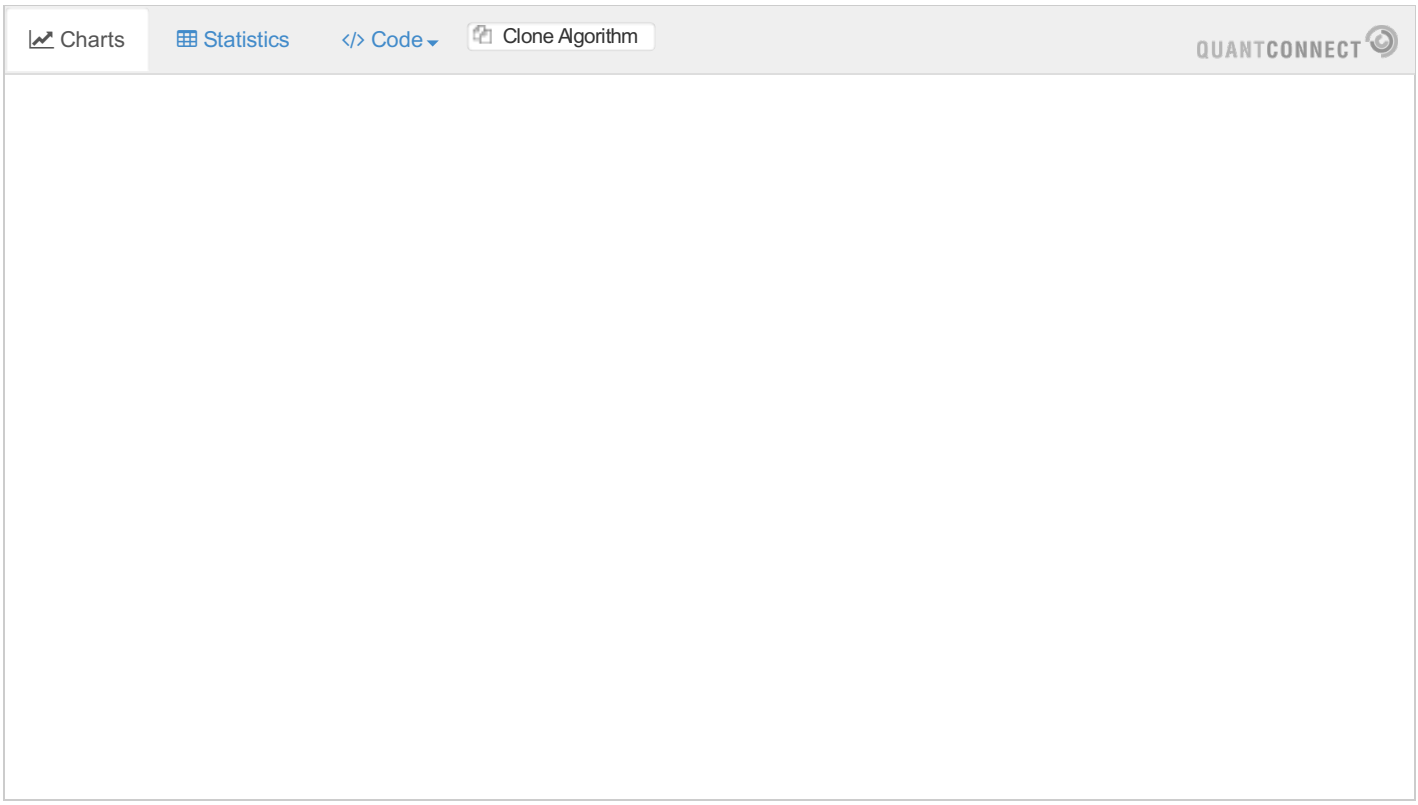
Asset	**Price ($)**	**Strike ($)**
OTM call	4.90	767.50
ATM call	15.00	800.00
ITM call	41.00	832.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{OTM})^{+}\\ & = & (767.50-829.08)^{+}\\ & = & 0\\ C^{ITM}_T & = & (S_T - K^{ITM})^{+}\\ & = & (832.50-829.08)^{+}\\ & = & 3.42\\ C^{ATM}_T & = & (S_T - K^{ATM})^{+}\\ & = & (800.00-829.08)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T + C^{ITM}_T - 2\times C^{ATM}_T + 2\times C^{ATM}_0 - C^{ITM}_0 - C^{OTM}_0)\times m - fee\\ & = & (0+3.42-0\times2-4.90-41.00+15.00\times2)\times100-1.00\times4\\ & = & -1252 \end{array}$$

So, the strategy losses $1,252.

The following algorithm implements a long call butterfly Option strategy:



Demonstration Algorithm
IndexOptionCallButterflyAlgorithm.py Python

Option Strategies

Put Butterfly

Introduction

Put butterfly is the combination of a bull put spread and a bear put spread . In this strategy, all the puts have the same underlying stock, the same expiration date, and the strike price distance of ITM-ATM and OTM-ATM put pairs are the same. The put butterfly strategy can be long or short.

Long Put Butterfly

The long put butterfly strategy consists of buying an ITM put, buying an OTM put, and selling 2 ATM puts. This strategy profits from low volatility.

Short Put Butterfly

The short put butterfly strategy consists of selling an ITM put, selling an OTM put, and buying 2 ATM puts. This strategy profits from a drastic change in underlying price.

Implementation

Follow these steps to implement the put butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```py
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 3, 5)
    self.SetCash(500000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(self.UniverseFunc)

def UniverseFunc(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return universe.IncludeWeeklys().Strikes(-15, 15).Expiration(timedelta(0), timedelta(31))
```

2. In the `OnData` method, select strikes and expiration date of the contracts in the strategy legs.

```
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Select an expiry date
    expiry = sorted(chain, key = lambda x: x.Expiry, reverse=True)[0].Expiry

    # Select the put contracts that expire on the selected date
    puts = [i for i in chain if i.Expiry == expiry and i.Right == OptionRight.Put]
    if len(puts) == 0: return

    # Sort the put contracts by their strike prices
    put_strikes = sorted([x.Strike for x in puts])

    # Get the ATM strike price
    atm_strike = sorted(puts, key=lambda x: abs(x.Strike - chain.Underlying.Price))[0].Strike

    # Get the distance between lowest strike price and ATM strike, and highest strike price and ATM
strike.
    # Get the lower value as the spread distance as equidistance is needed for both sides
    spread = min(abs(put_strikes[0] - atm_strike), abs(put_strikes[-1] - atm_strike))

    # Select the strike prices of the strategy legs
    itm_strike = atm_strike + spread
    otm_strike = atm_strike - spread
```

3. In the `OnData` method, call the `OptionStrategies.PutButterfly` method and then submit the order.

```
option_strategy = OptionStrategies.PutButterfly(self.symbol, itm_strike, atm_strike, otm_strike,
expiry)
self.Buy(option_strategy, 1)    # if long put butterfly
self.Sell(option_strategy, 1)   # if short put butterfly
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` and `Sell` methods.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
self.Sell(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

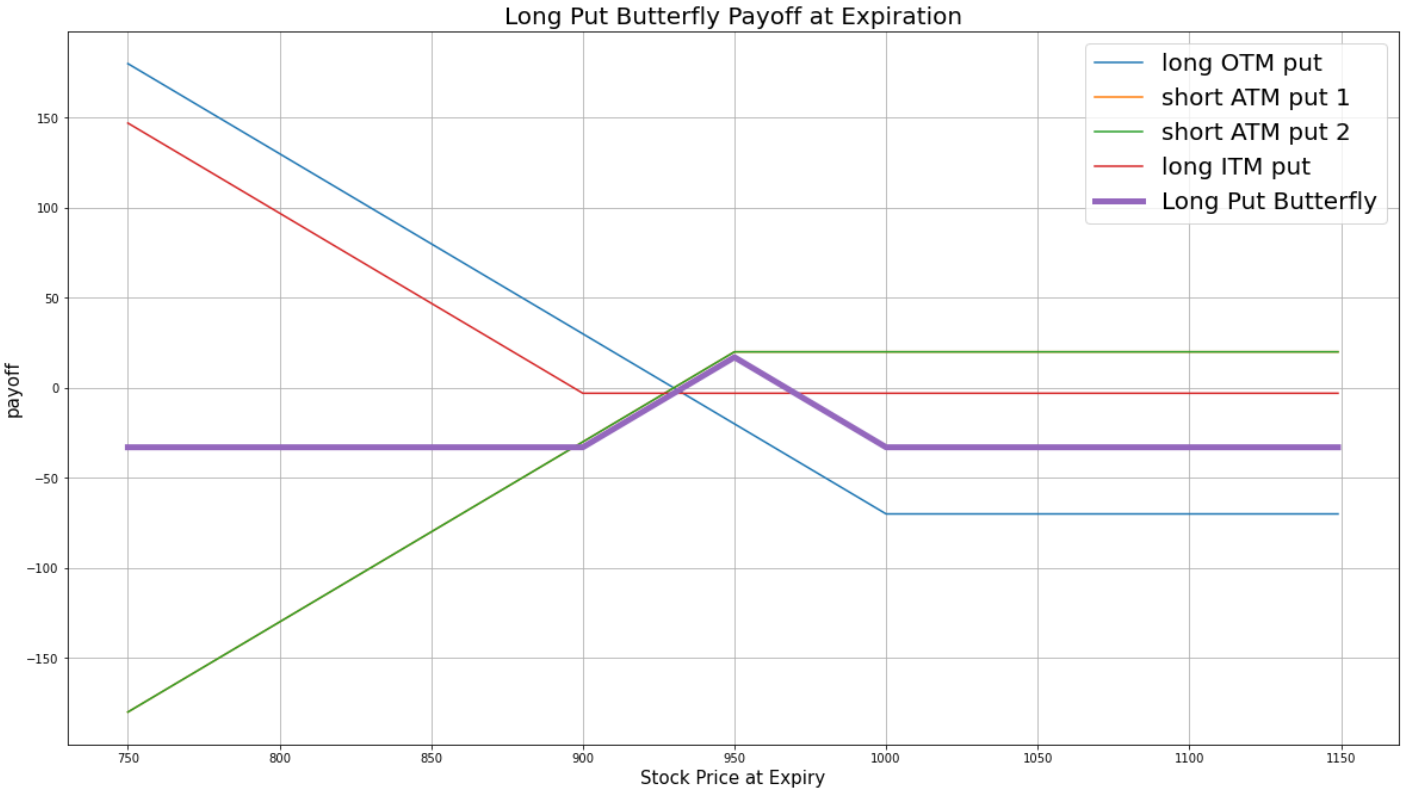
The put butterfly can be long or short.

Long Put Butterfly

The long put butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{OTM}_T &=& (K^{OTM} - S_T)^{+}\\ P^{ITM}_T &=& (K^{ITM} - S_T)^{+}\\ P^{ATM}_T &=& (K^{ATM} - S_T)^{+}\\ P_T &=& (P^{OTM}_T + P^{ITM}_T - 2\times P^{ATM}_T + 2\times P^{ATM}_0 - P^{ITM}_0 - P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & P^{OTM}_T &=& \textrm{OTM put value at time T}\\ & P^{ITM}_T &=& \textrm{ITM put value at time T}\\ & P^{ATM}_T &=& \textrm{ATM put value at time T}\\ & S_T &=& \textrm{Underlying asset price at time T}\\ & K^{OTM} &=& \textrm{OTM put strike price}\\ & K^{ITM} &=& \textrm{ITM put strike price}\\ & K^{ATM} &=& \textrm{ATM put strike price}\\ & P_T &=& \textrm{Payout total at time T}\\ & P^{ITM}_0 &=& \textrm{ITM put value at position opening (debit paid)}\\ & P^{OTM}_0 &=& \textrm{OTM put value at position opening (debit paid)}\\ & P^{ATM}_0 &=& \textrm{ATM put value at position opening (credit received)}\\ & m &=& \textrm{Contract multiplier}\\ & T &=& \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K^{ATM} - K^{OTM} + 2\times P^{ATM}_0 - P^{ITM}_0 - P^{OTM}_0$. It occurs when the underlying price is the same at expiration as it was when you open the trade. In this case, the payout of the combined bull put and bear put spreads are at their maximum.

The maximum loss is the net debit paid, $2\times P^{ATM}_0 - P^{ITM}_0 - P^{OTM}_0$. It occurs when the underlying price is below the ITM strike price or above the OTM strike price at expiration.

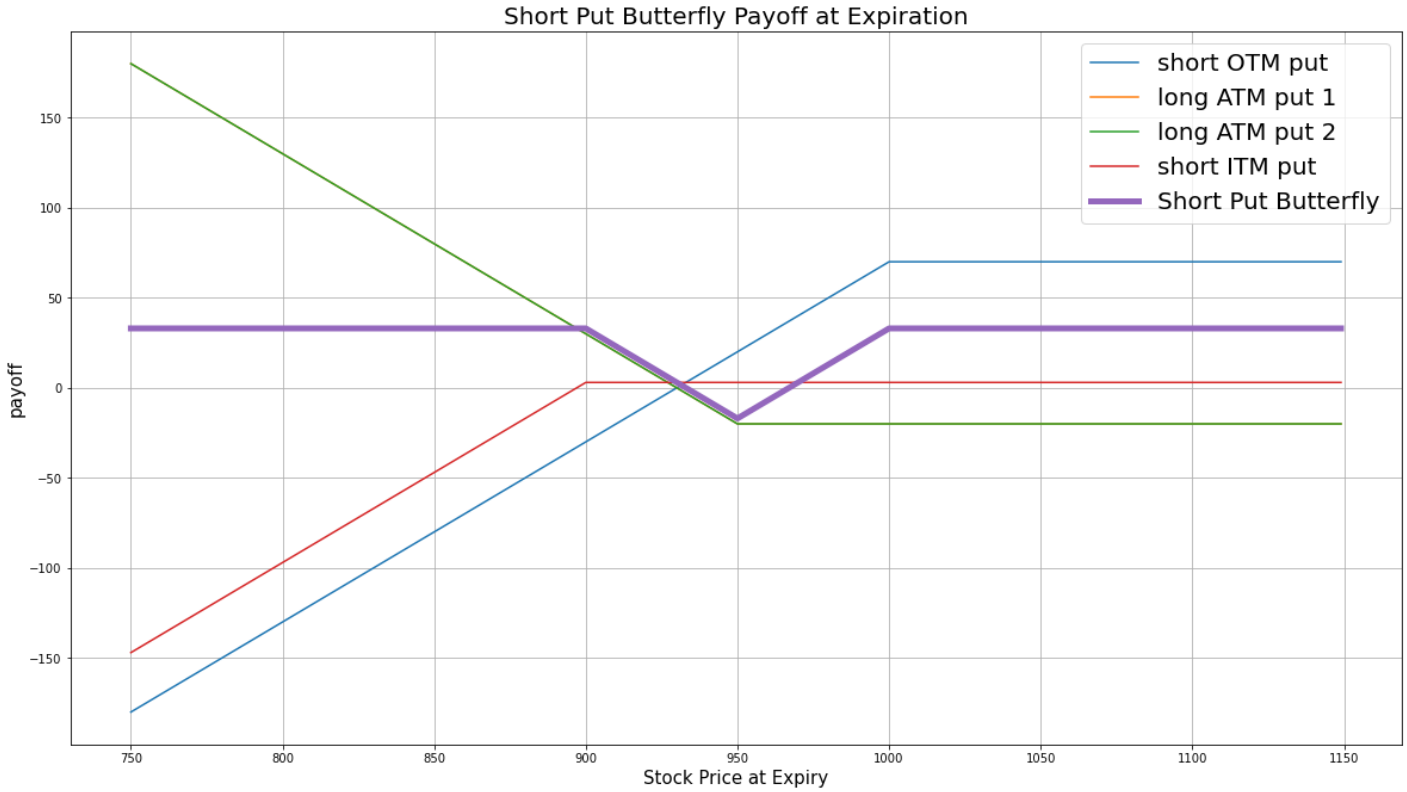
If the Option is American Option, there is risk of early assignment on the sold contracts.

Short Put Butterfly

The short put butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ P^{ATM}_T & = & (K^{ATM} - S_T)^{+}\\ P_T & = & (2\times P^{ATM}_T - P^{OTM}_T - P^{ITM}_T - 2\times P^{ATM}_0 + P^{ITM}_0 + P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ITM}_T & = & \textrm{ITM put value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{OTM} & = & \textrm{OTM put strike price}\\ & K^{ITM} & = & \textrm{ITM put strike price}\\ & K^{ATM} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{ITM}_0 & = & \textrm{ITM put value at position opening (credit received)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (credit received)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, $P^{ITM}_0 + P^{OTM}_0 - 2\times P^{ATM}_0$. It occurs when the underlying price is below the ITM strike or above the OTM strike at expiration.

The maximum loss is $K^{ATM} - K^{OTM} - 2\times P^{ATM}_0 + P^{ITM}_0 + P^{OTM}_0$. It occurs when the underlying price at expiration is at the same price as when you opened the trade.

If the Option is American Option, there is risk of early assignment on the sold contracts.

Example

The following table shows the price details of the assets in the long put butterfly algorithm:

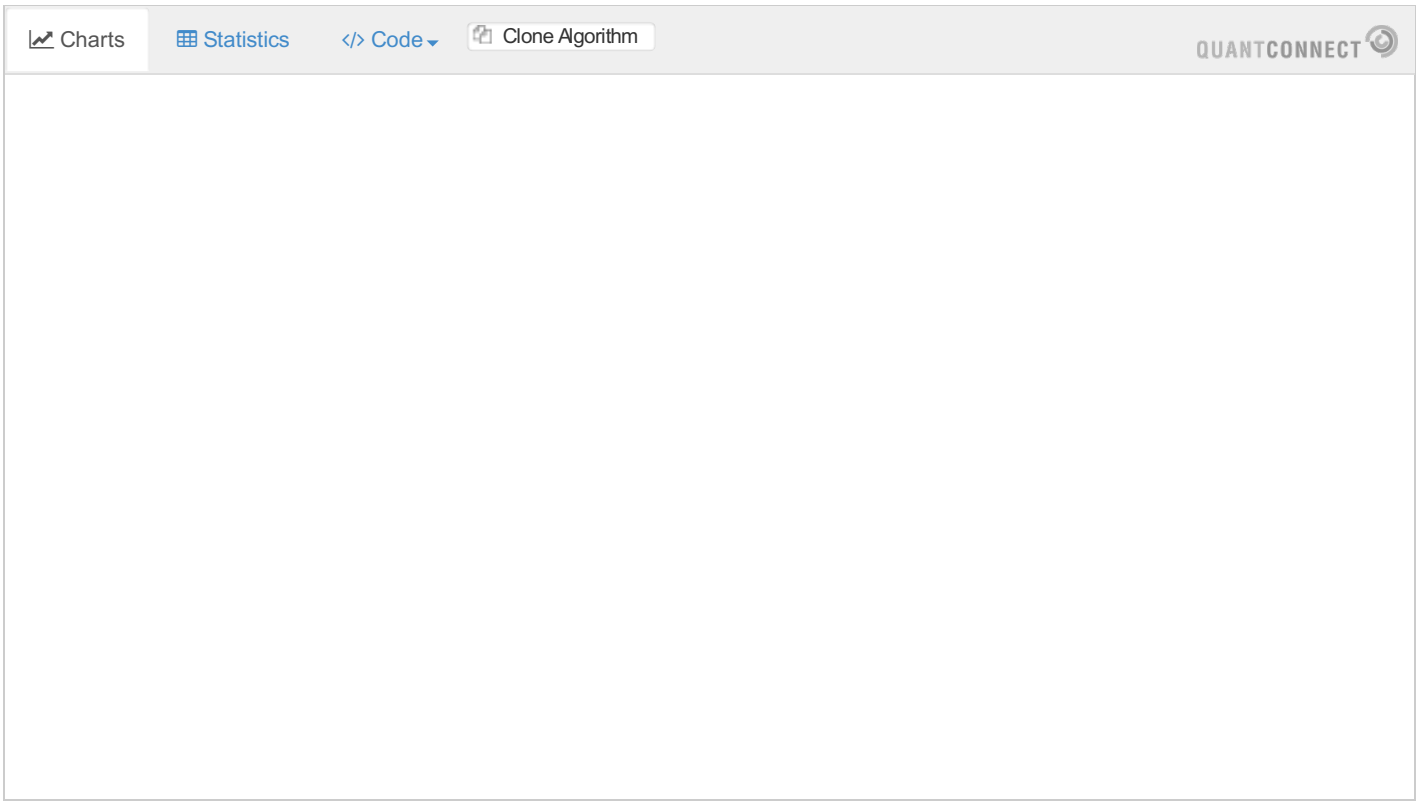
Asset	**Price ($)**	**Strike ($)**
ITM put	37.80	832.50
ATM put	14.70	800.00
OTM put	5.70	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{OTM}_T & = & (K^{OTM} - S_T)^{+}\\ & = & (829.08-832.50)^{+}\\ & = & 0\\ P^{ITM}_T & = & (K^{ITM} - S_T)^{+}\\ & = & (829.08-767.50)^{+}\\ & = & 61.58\\ P^{ATM}_T & = & (K^{ATM} - S_T)^{+}\\ & = & (829.08-800.00)^{+}\\ & = & 29.08\\ P_T & = & (P^{OTM}_T + P^{ITM}_T - 2\times P^{ATM}_T + 2\times P^{ATM}_0 - P^{ITM}_0 - P^{OTM}_0)\times m - fee\\ & = & (61.58+0-29.08\times2-5.70-37.80+14.70\times2)\times100-1.00\times4\\ & = & -1072 \end{array}$$

So, the strategy losses $1,072.

The following algorithm implements a long put butterfly Option strategy:



Demonstration Algorithm
IndexOptionPutButterflyAlgorithm.py Python

Option Strategies

Call Calendar Spread

Introduction

Call calendar spread , also known as **call horizontal spread** , is a combination of a longer-term (far-leg/front-month) call and a shorter-term (near-leg/back-month) call, where all calls have the same underlying stock and the same strike price. The call calendar spread can be long or short.

Long Call Calendar Spread

The long call calendar spread consists of buying a longer-term call and selling a shorter-term call. This strategy profits from a decrease in the underlying price. It also profits from the time decay value because the theta θ (the Option price decay by 1 day closer to maturity) of the shorter-term call is larger than longer-term call.

Short Call Calendar Spread

The short call calendar spread consists of selling a longer-term call and buying a shorter-term call. The strategy profits from from an increase in the underlying price.

Implementation

Follow these steps to implement the call calendar spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 2, 19)
    self.SetCash(500000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(self.UniverseFunc)

def UniverseFunc(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return universe.Strikes(-1, 1).Expiration(timedelta(0), timedelta(62))
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```py
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Get the ATM strike
    atm_strike = sorted(chain, key=lambda x: abs(x.Strike - chain.Underlying.Price))[0].Strike

    # Select the ATM call Option contracts
    calls = [i for i in chain if i.Strike == atm_strike and i.Right == OptionRight.Call]
    if len(calls) == 0: return

    # Select the near and far expiry dates
    expiries = sorted([x.Expiry for x in calls])
    near_expiry = expiries[0]
    far_expiry = expiries[-1]
```

3. In the `OnData` method, call the `OptionStrategies.CallCalendarSpread` method and then submit the order.

```py
option_strategy = OptionStrategies.CallCalendarSpread(self.symbol, atm_strike, near_expiry,
far_expiry)
self.Buy(option_strategy, 1)    # if long call calendar spread
self.Sell(option_strategy, 1)   # if short call calendar spread
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` and `Sell` methods.

```py
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
self.Sell(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

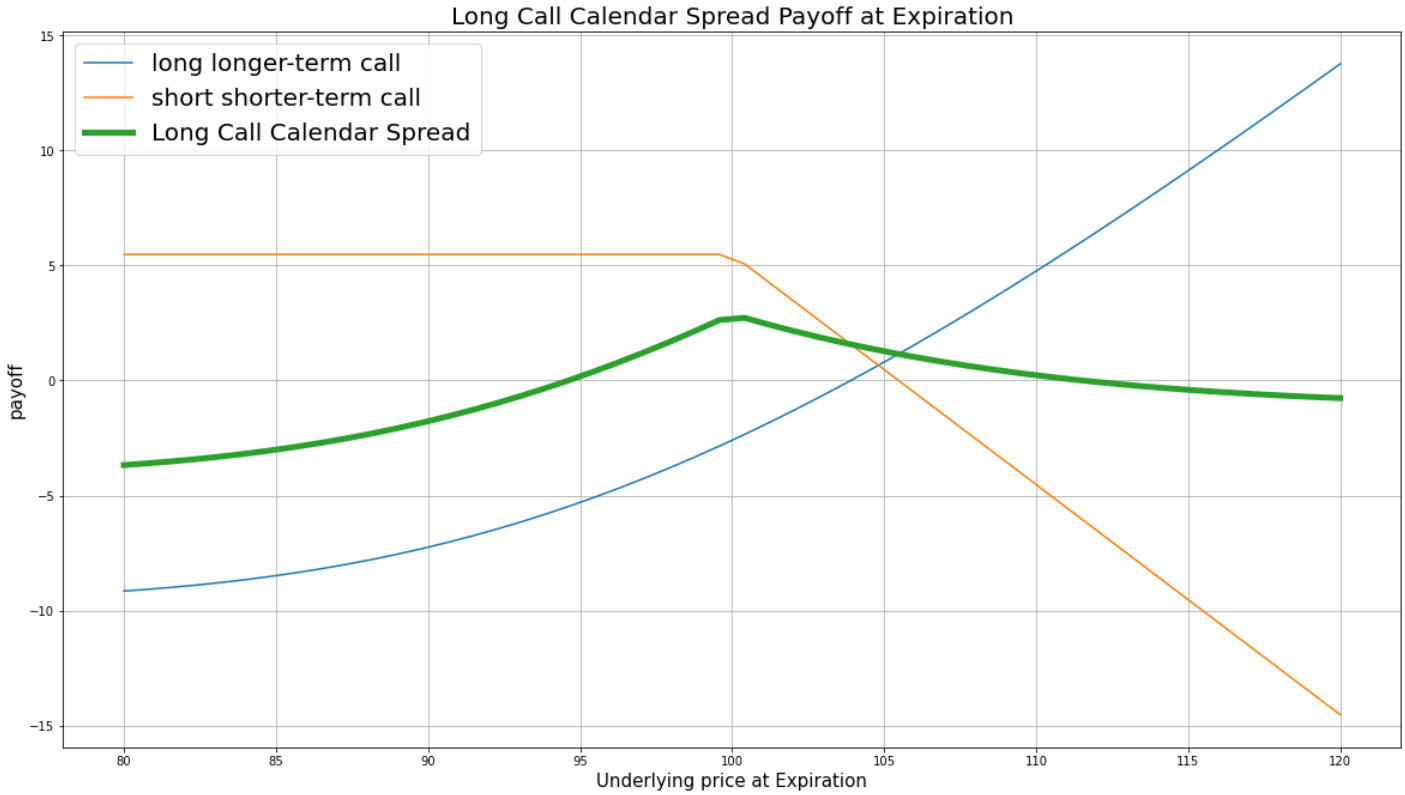
The call calendar spread can be long or short.

Long Call Calendar Spread

The long call calendar spread is a limited-reward-limited-risk strategy. The payoff at the shorter-term expiration is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ P_T & = & (C^{\textrm{long-term}}_T - C^{\textrm{short-term}}_T + C^{\textrm{short-term}}_0 - C^{\textrm{long-term}}_0)\times m - fee\\ \end{array}$$
$$\begin{array}{rcll} \textrm{where} & C^{\textrm{short-term}}_T & = & \textrm{Shorter term call value at time T}\\ & C^{\textrm{long-term}}_T & = & \textrm{Longer term call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{\textrm{short-term}}_0 & = & \textrm{Shorter term call value at position opening (credit received)}\\ & C^{\textrm{long-term}}_0 & = & \textrm{Longer term call value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of shorter term call expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the calls are at their maximum.

The maximum loss is the net debit paid, $C^{\textrm{short-term}}_0 - C^{\textrm{long-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both calls are close to zero.

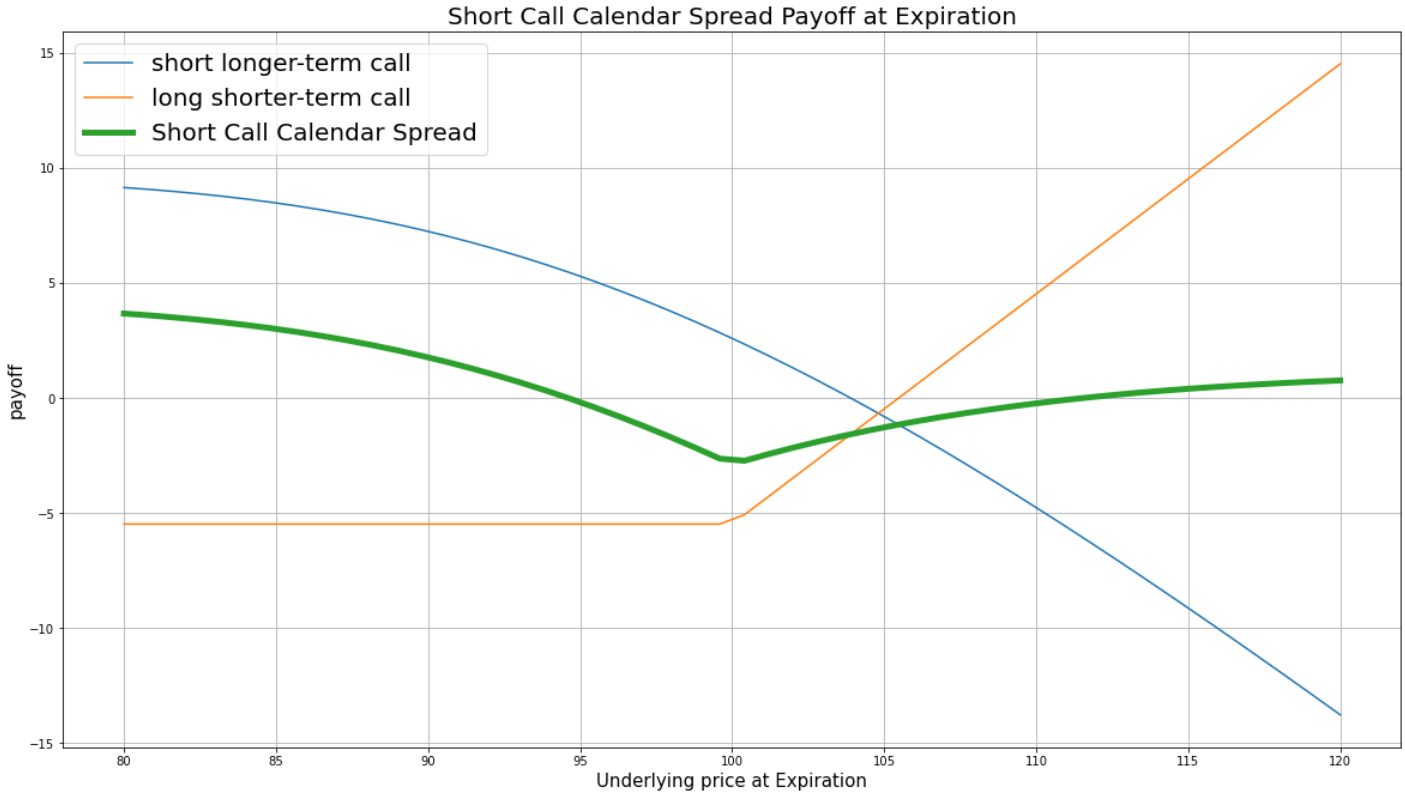
If the Option is American Option, there is risk of early assignment on the sold contract. If the buyer exercises the call you sell, you could lose all the debit you received if you don't close the long call and the underlying price drops below the long call strike price.

Short Call Calendar Spread

The short call calendar spread is a limited-reward-limited-risk strategy. The payoff at the shorter-term expiration is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ P_T & = & (C^{\textrm{short-term}}_T - C^{\textrm{long-term}}_T + C^{\textrm{long-term}}_0 - C^{\textrm{short-term}}_0)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & C^{\textrm{short-term}}_T & = & \textrm{Shorter term call value at time T}\\ & C^{\textrm{long-term}}_T & = & \textrm{Longer term call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{\textrm{short-term}}_0 & = & \textrm{Shorter term call value at position opening (debit paid)}\\ & C^{\textrm{long-term}}_0 & = & \textrm{Longer term call value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of shorter term call expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, C^{\textrm{long-term}}_0 - C^{\textrm{short-term}}_0. It occurs when the underlying price moves very deep ITM or OTM so the values of both calls are close to zero.

The maximum loss is undetermined because it depends on the underlying volatility. It occurs when S_T = S_0 and the spread of the 2 calls are at their maximum.

If the Option is American Option, there is risk of early assignment on the sold contract. If you don't close the call positions together, the naked short call will have unlimited drawdown risk after the long call expires.

Example

The following table shows the price details of the assets in the long version algorithm:

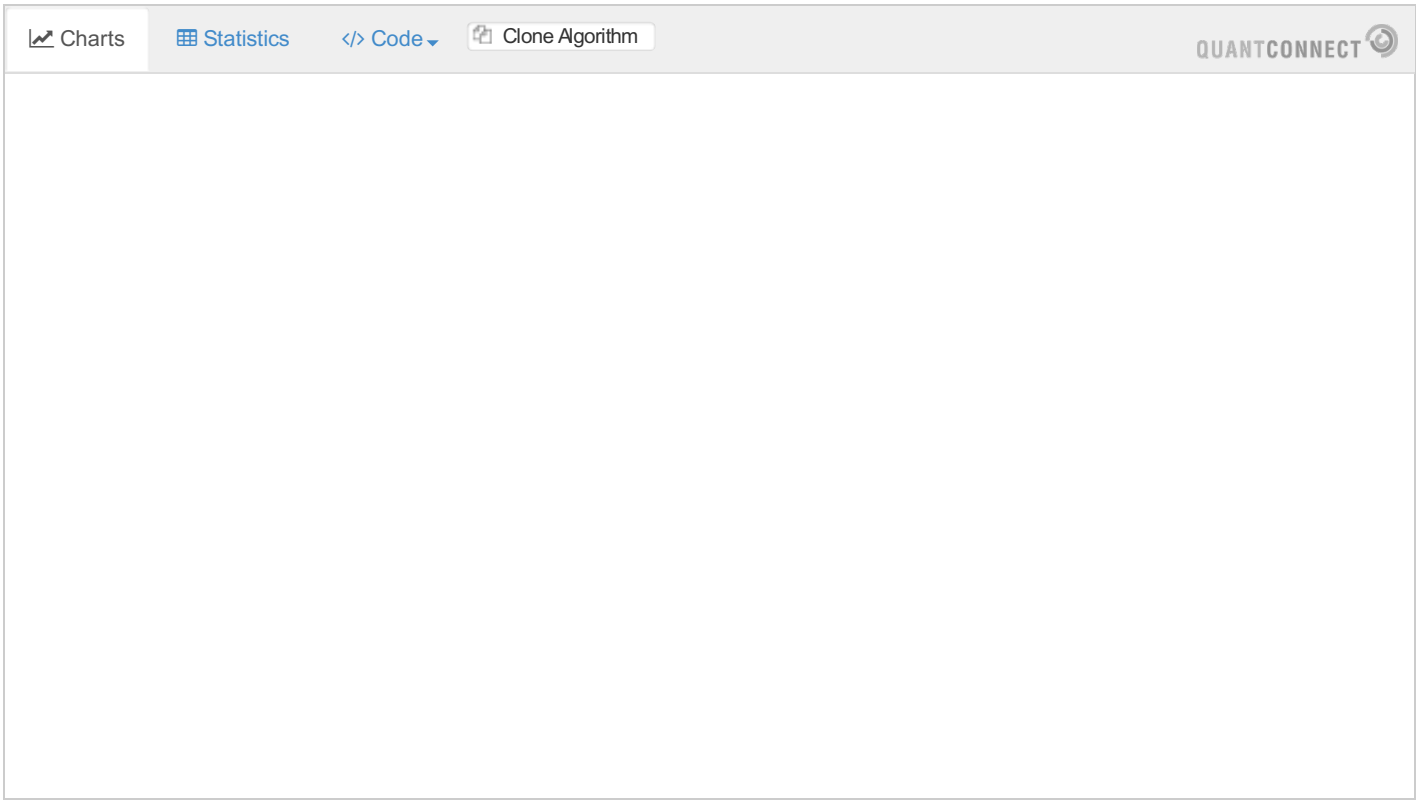
Asset	**Price ($)**	**Strike ($)**
Longer-term call at the start of the trade	4.40	835.00
Shorter-term call at the start of the trade	36.80	767.50
Longer-term call at time T	31.35	835.00
Underlying Equity at time T	829.08	-

Therefore, the payoff at time T (the expiration of the short-term call) is

\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ & = & (828.07-800.00)^{+}\\ & = & 28.07\\ P_T & = & (C^{\textrm{long-term}}_T - C^{\textrm{short-term}}_T + C^{\textrm{short-term}}_0 - C^{\textrm{long-term}}_0)\times m - fee\\ & = & (31.35-28.07+11.30-20.00)\times100-1.00\times2\\ & = & -544 \end{array}

So, the strategy losses $544.

The following algorithm implements a long call calendar spread Option strategy:



Demonstration Algorithm
IndexOptionCallCalendarSpreadAlgorithm.py Python

Option Strategies

Put Calendar Spread

Introduction

Put calendar spread , also known as **put horizontal spread** , is a combination of a longer-term (far-leg/front-month) put and a shorter-term (near-leg/back-month) put, where both puts have the same underlying stock and the same strike price. The put calendar spread strategy can be long or short.

Long Put Calendar Spread

The long put calendar spread consists of buying a longer-term put and selling a shorter-term put. This strategy profits from a decrease in price movement. The strategy also profits from the time decay value because the theta θ (the Option price decay by 1 day closer to maturity) of the shorter-term put is larger than the longer-term put.

Short Put Calendar Spread

The short put calendar spread consists of selling a longer-term put and buying a shorter-term put. This strategy profits from an increase in price movement.

Implementation

Follow these steps to implement the put calendar spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 2, 19)
    self.SetCash(500000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(self.UniverseFunc)

def UniverseFunc(self, universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return universe.Strikes(-1, 1).Expiration(timedelta(0), timedelta(62))
```

2. In the `OnData` method, select the strike price and expiration dates of the contracts in the strategy legs.

```py
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Get the ATM strike price
    atm_strike = sorted(chain, key=lambda x: abs(x.Strike - chain.Underlying.Price))[0].Strike

    # Select the ATM put contracts
    puts = [i for i in chain if i.Strike == atm_strike and i.Right == OptionRight.Put]
    if len(puts) == 0: return

    # Select the near and far expiration dates
    expiries = sorted([x.Expiry for x in puts], key = lambda x: x)
    near_expiry = expiries[0]
    far_expiry = expiries[-1]
```

3. In the `OnData` method, call the `OptionStrategies.PutCalendarSpread` method and then submit the order.

```py
option_strategy = OptionStrategies.PutCalendarSpread(self.symbol, atm_strike, near_expiry,
far_expiry)
self.Buy(option_strategy, 1)    # if long put calendar spread
self.Sell(option_strategy, 1)   # if short put calendar spread
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` and `Sell` methods.

```py
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
self.Sell(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

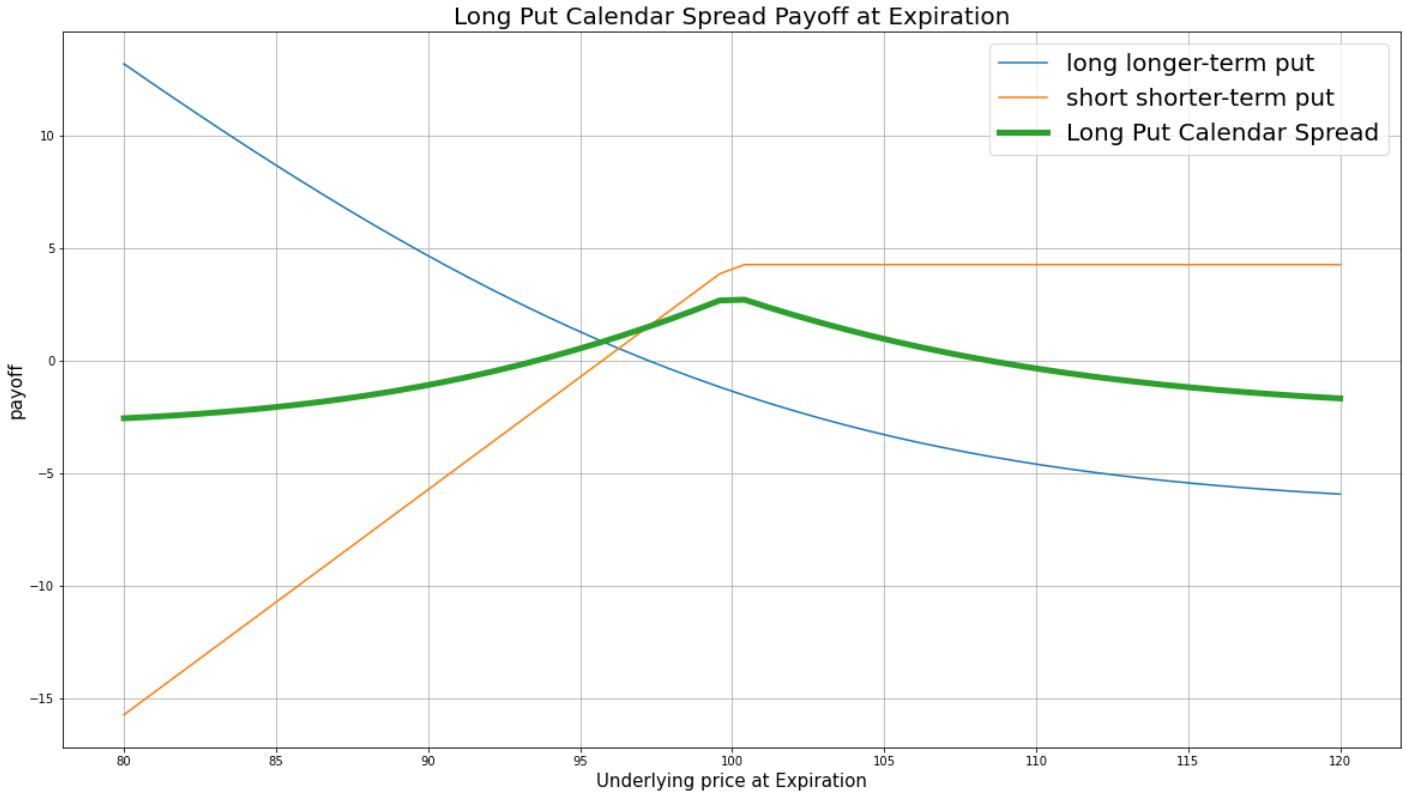
The put calendar spread can be long or short.

Long Put Calendar Spread

The long put calendar spread is a limited-reward-limited-risk strategy. The payoff is taken at the shorter-term expiration. The payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ P_T & = & (P^{\textrm{long-term}}_T - P^{\textrm{short-term}}_T + P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & P^{\textrm{short-term}}_T & = & \textrm{Shorter term put value at time T}\\ & P^{\textrm{long-term}}_T & = & \textrm{Longer term put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{\textrm{short-term}}_0 & = & \textrm{Shorter term put value at position opening (credit received)}\\ & P^{\textrm{long-term}}_0 & = & \textrm{Longer term put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of shorter term put expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the puts are at their maximum.

The maximum loss is the net debit paid, $P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both puts are close to zero.

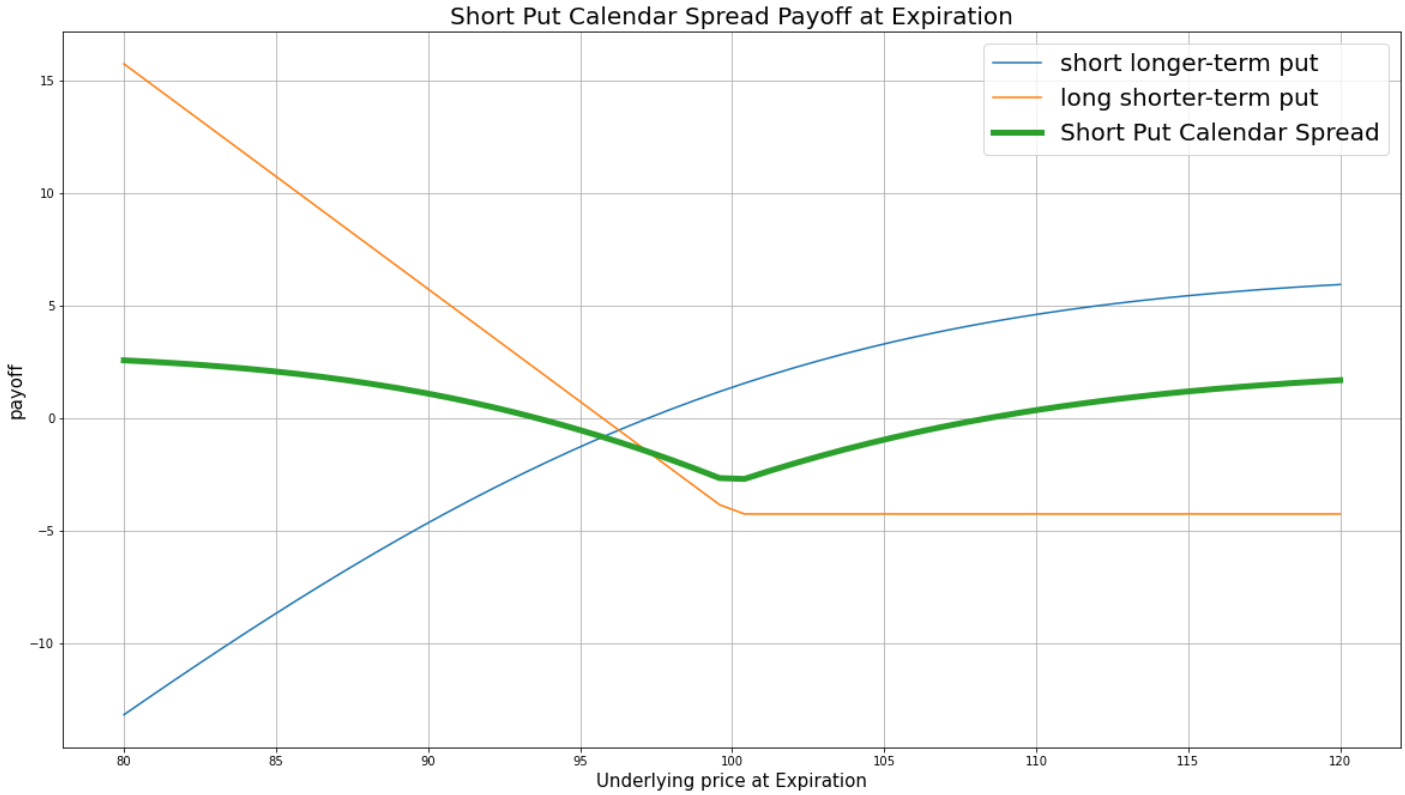
If the Option is American Option, there is risk of early assignment on the sold contract. Naked long puts pose risk of losing all the debit paid if you don't close the position with short put together and the price drops below its strike.

Short Put Calendar Spread

The short put calendar spread is a limited-reward-limited-risk strategy. The payoff is taken at the shorter-term expiration. The payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ P_T & = & (P^{\textrm{short-term}}_T - P^{\textrm{long-term}}_T + P^{\textrm{long-term}}_0 - P^{\textrm{short-term}}_0)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & P^{\textrm{short-term}}_T & = & \textrm{Shorter term put value at time T}\\ & P^{\textrm{long-term}}_T & = & \textrm{Longer term put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{\textrm{short-term}}_0 & = & \textrm{Shorter term put value at position opening (debit paid)}\\ & P^{\textrm{long-term}}_0 & = & \textrm{Longer term put value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of shorter term put expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, $P^{\textrm{long-term}}_0 - P^{\textrm{short-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both puts are close to zero.

The maximum loss is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the 2 puts are at their maximum.

If the Option is American Option, there is risk of early assignment on the sold contract. Additionally, if you don't close the put positions together, the naked short put will have unlimited drawdown risk after the long put expires.

Example

The following table shows the price details of the assets in the long put calendar spread algorithm:

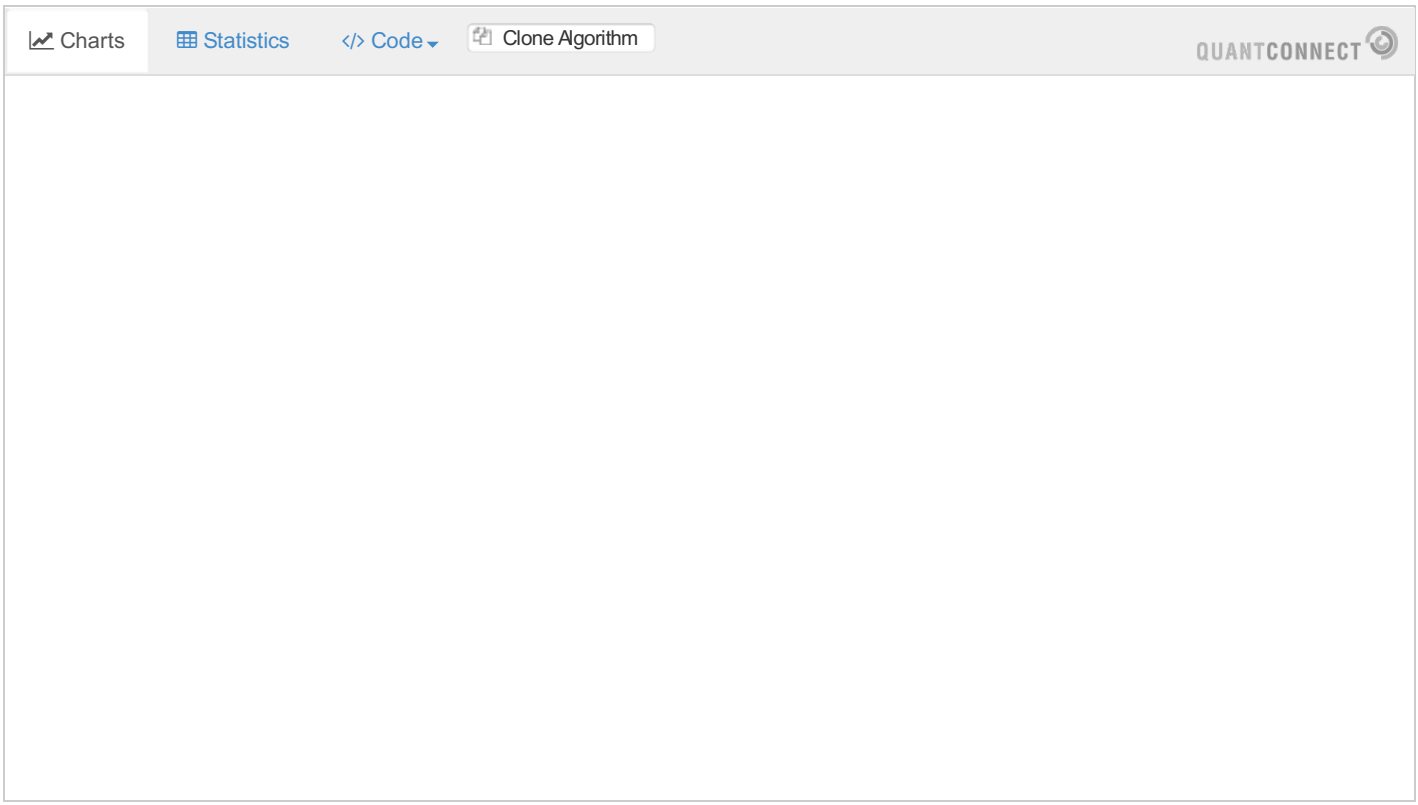
Asset	**Price ($)**	**Strike ($)**
Shorter-term put at position opening	11.30	800.00
Longer-term put at position opening	19.30	800.00
Longer-term put at shorter-term expiration	3.50	800.00
Underlying Equity at shorter-term expiration	828.07	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ & = & (800.00-828.07)^{+}\\ & = & 0\\ P_T & = & (P^{\textrm{long-term}}_T - P^{\textrm{short-term}}_T + P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0)\times m - fee\\ & = & (3.50-0+11.30-19.30)\times100-1.00\times2\\ & = & -452\\ \end{array}$$

So, the strategy losses $452.

The following algorithm implements a long put calendar spread Option strategy:



Demonstration Algorithm
IndexOptionPutCalendarSpreadAlgorithm.py Python

Option Strategies

Covered Call

Introduction

A **Covered Call** consists of a long position in a stock and a short position in call Options for the same amount of stock. Covered calls aim to profit from the Option premium by selling calls written on the stock you already own. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, you keep the premium and still maintain the underlying Equity position. If the underlying price moves above the strike, the Option buyer can exercise the Options contract , which means you sell your stock at the strike price and keep the premium. Another risk of a covered call comes from the long stock position, which can drop in value.

Implementation

Follow these steps to implement the covered call strategy:

1. In the `Initialize` method, set the start date, end date, starting cash, and Options universe .

```
PY
def Initialize(self) -> None:
    self.SetStartDate(2014, 1, 1)
    self.SetEndDate(2014, 3, 1)
    self.SetCash(100000)

    option = self.AddOption("IBM")
    self.symbol = option.Symbol
    self.call = None

    option.SetFilter(-3, 3, 0, 31)
```

2. In the `OnData` method, select the Option contract.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.call and self.Portfolio[self.call].Invested:
        return

    chain = slice.OptionChains.get(self.symbol)
    if not chain:
        return

    # Find ATM call with the farthest expiry
    expiry = max([x.Expiry for x in chain])
    call_contracts = sorted([x for x in chain
        if x.Right == OptionRight.Call and x.Expiry == expiry],
        key=lambda x: abs(chain.Underlying.Price - x.Strike))

    if not call_contracts:
        return

    atm_call = call_contracts[0]
```

3. In the `OnData` method, call the `OptionStrategies.CoveredCall` method and then submit the order.

```
covered_call = OptionStrategies.CoveredCall(self.symbol, atm_call.Strike, expiry)
self.Buy(covered_call, 1)

self.call = atm_call.Symbol
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

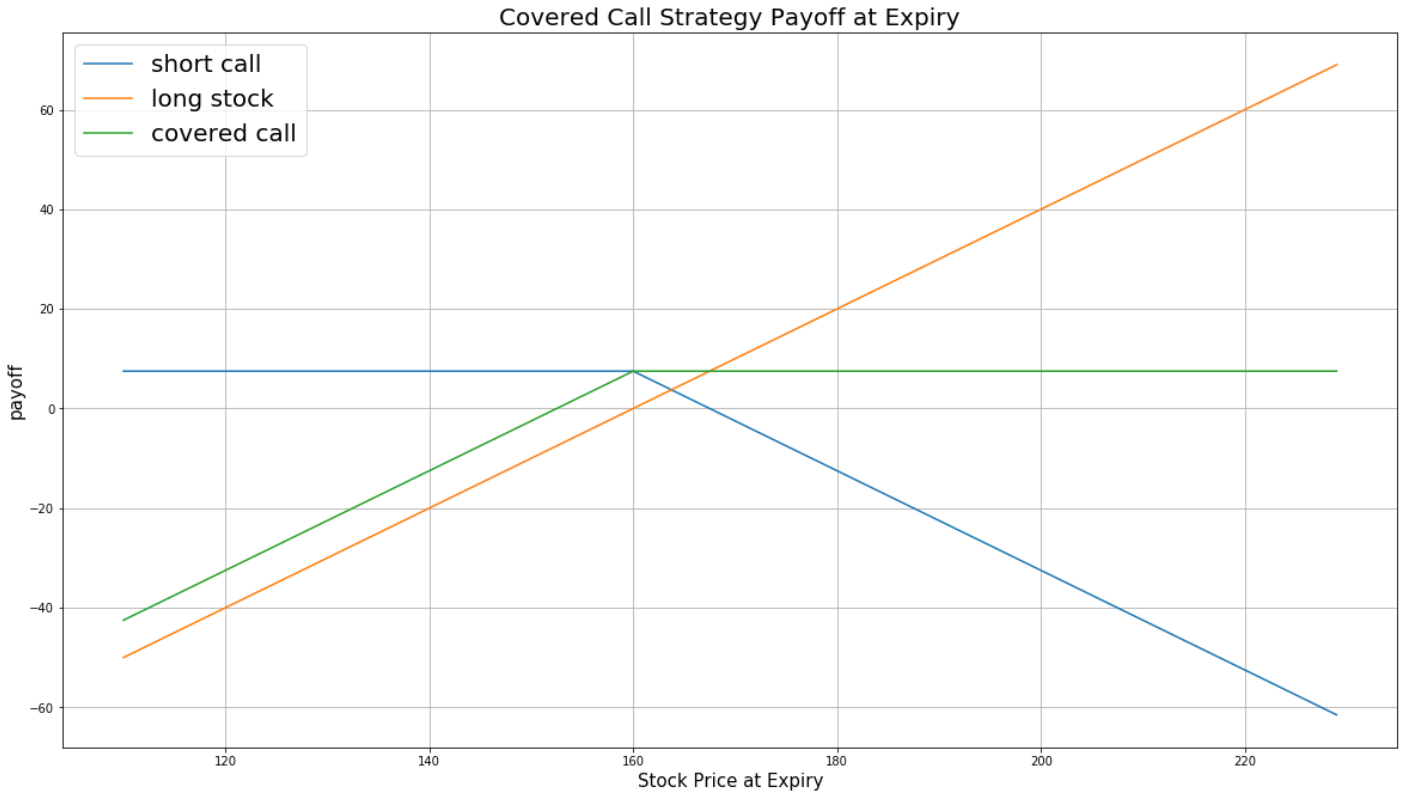
```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ P_T & = & (S_T - S_0 + C^{K}_0 - C^{K}_T)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & C^{K}_T & = & \textrm{Call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C^{K}_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K - S_T + C^{K}_0$, which occurs when the underlying price is at or above the strike price of the call at expiration.

The maximum loss is $S_0 - C^{K}_0$, which ocurrs when the underlying price drops.

If the Option is American Option, there is risk of early assignment on the sold contract.

Example

The following table shows the price details of the assets in the algorithm:

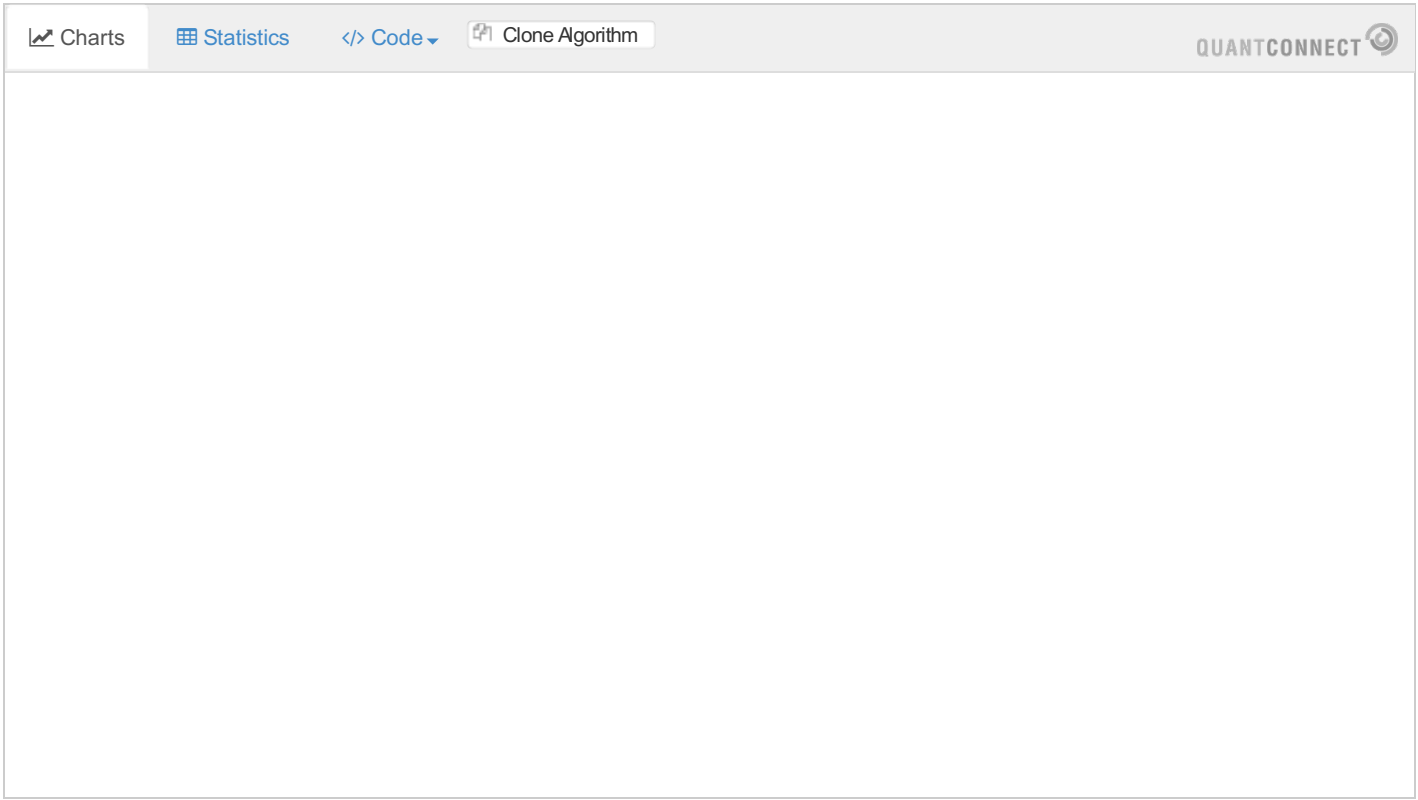
Asset	Price ($)	Strike ($)
Call	3.35	185.00
Underlying Equity at start of the trade	187.07	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ & = & (190.01 - 185)^{+}\\ & = & 5.01\\ P_T & = & (S_T - S_0 + C^{K}_0 - C^{K}_T)\times m - fee\\ & = & (190.01 - 187.07 + 3.35 - 5.01)\times m - fee\\ & = & 1.28 \times 100 - 2\\ & = & 126 \end{array}$$

So, the strategy gains $126.

The following algorithm implements a covered call strategy:



Option Strategies

Covered Put

Introduction

A **Covered Put** consists of a short position in a stock and a short position in put Options for the same amount of stock. Covered puts aim to profit from the Option premium by selling puts written on the stock you already shorted. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, you keep the premium and still maintain the underlying Equity position. If the underlying price moves above the strike, the Option buyer can exercise the Options contract , which mean you buy the stock at the strike price but you will still keep the premium. Another risk of a covered put comes from the short stock position, which can drop in value.

Implementation

Follow these steps to implement the covered put strategy:

1. In the `Initialize` method, set the start date, end date, starting cash, and Options universe .

```
PY
def Initialize(self) -> None:
    self.SetStartDate(2014, 1, 1)
    self.SetEndDate(2014, 3, 1)
    self.SetCash(100000)

    option = self.AddOption("IBM")
    self.symbol = option.Symbol
    self.put = None

    option.SetFilter(-3, 3, 0, 31)
```

2. In the `OnData` method, select the Option contract.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.put and self.Portfolio[self.put].Invested:
        return

    chain = slice.OptionChains.get(self.symbol)
    if not chain:
        return

    # Find ATM put with the farthest expiry
    expiry = max([x.Expiry for x in chain])
    put_contracts = sorted([x for x in chain
        if x.Right == OptionRight.Put and x.Expiry == expiry],
        key=lambda x: abs(chain.Underlying.Price - x.Strike))

    if not put_contracts:
        return

    atm_put = put_contracts[0]
```

3. In the `OnData` method, put the `OptionStrategies.CoveredPut` method and then submit the order.

```
covered_put = OptionStrategies.CoveredPut(self.symbol, atm_put.Strike, expiry)
self.Buy(covered_put, 1)

self.put = atm_put.Symbol
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ P_T & = & (S_0 - S_T + P^{K}_0 - P^{K}_T)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & P^{K}_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & P^{K}_0 & = & \textrm{Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:

The maximum profit is $S_T - K + P^{K}_0$. It occurs when the underlying price is at or below the strike price of the put at expiration.

If the underlying price increase, the maximum loss is unlimited.

If the Option is American Option, there is risk of early assignment on the sold contract.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Put	1.37	185.00
Underlying Equity at start of the trade	186.94	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ & = & (185 - 190.01)^{+}\\ & = & 0\\ P_T & = & (S_0 - S_T + P^{K}_0 - P^{K}_T)\times m - fee\\ & = & (186.94 - 190.01 + 1.37 - 0)\times m - fee\\ & = & -1.70 \times 100 - 2\\ & = & -172 \end{array}$$

So, the strategy loses $172.

QUANTCONNECT

Option Strategies

Iron Butterfly

Introduction

Warning: There is currently no `OptionStrategies` method for Iron Butterfly orders, so this tutorial manually orders the individual legs in the strategy. If you manually place multi-leg orders one at a time while there is no liquidity at a strike price, you can get stuck in an unhedged position.

The **Iron Butterfly** is an option strategy which involves four Option contracts. All the contracts have the same underlying stock and expiration, but the order of strike prices for the four contracts is A>B>C. The following table describes the strike price of each contract:

Position	Strike
1 OTM call	A
1 ATM call	B
1 ATM put	B
1 OTM put	C=B-(A-B)

The iron butterfly can be long or short.

Long Iron Butterfly

The long iron butterfly consists of selling an OTM call, selling an OTM put, buying an ATM call, and buying an ATM put. This strategy profits from a decrease in price movement (implied volatility).

Short Call Butterfly

The short call butterfly consists of buying an OTM call, buying an OTM put, selling an ATM call, and selling an ATM put. This strategy profits from an increase in price movement (implied volatility) and from time decay value since ATM options decay sharper.

Implementation

Follow these steps to implement the short iron butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
def Initialize(self) -> None:
    self.SetStartDate(2017, 4, 1)
    self.SetEndDate(2017, 5, 10)
    self.SetCash(100000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(-10, 10, timedelta(0), timedelta(30))
```

2. In the `OnData` method, select the contracts in the strategy legs.

```
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Separate the call and put contracts
    call = [i for i in chain if i.Right == 0]
    put = [i for i in chain if i.Right == 1]
    if len(call) == 0 or len(put) == 0 : return

    # Select the OTM contracts
    call_contracts = sorted(call, key = lambda x: x.Strike)
    put_contracts = sorted(put, key = lambda x: x.Strike)
    otm_call = call_contracts[-1]
    otm_put = put_contracts[0]

    # Select the ATM contracts
    atm_put = sorted(put_contracts, key = lambda x: abs(chain.Underlying.Price - x.Strike))[0]
    atm_call = sorted(call_contracts, key = lambda x: abs(chain.Underlying.Price - x.Strike))[0]
```

3. In the `OnData` method, submit the orders.

```
self.Sell(atm_put.Symbol, 1)
self.Sell(atm_call.Symbol, 1)
self.Buy(otm_call.Symbol, 1)
self.Buy(otm_put.Symbol, 1)
```

Strategy Payoff

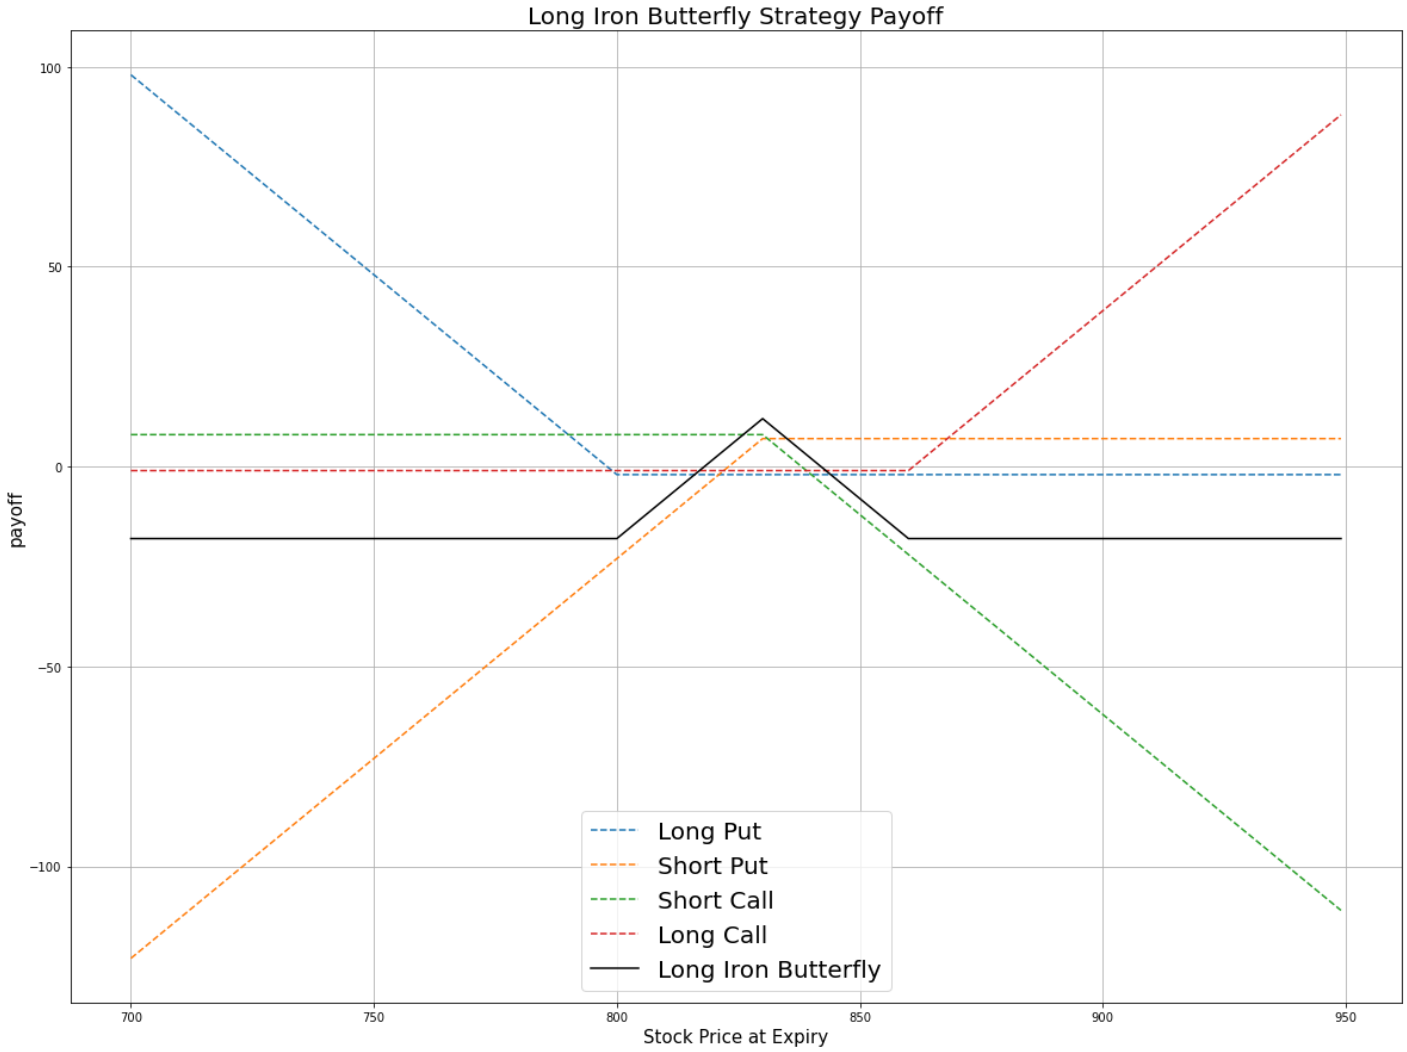
The iron butterfly can be long or short.

Long Iron Butterfly

The long iron butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{OTM}_T - P^{OTM}_T - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{OTM} & = & \textrm{OTM call strike price}\\ & K^C_{ATM} & = & \textrm{ATM call strike price}\\ & K^P_{OTM} & = & \textrm{OTM put strike price}\\ & K^P_{ATM} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (credit received)}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (credit received)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is K^C_{OTM} - K^C_{ATM} - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0. It occurs when the underlying price is below the OTM put strike price or above the OTM call strike price at expiration.

The maximum loss is the net debit paid, C^{OTM}_0 + P^{OTM}_0 - C^{ATM}_0 - P^{ATM}_0. It occurs when the underlying price stays the same as when you opened the trade.

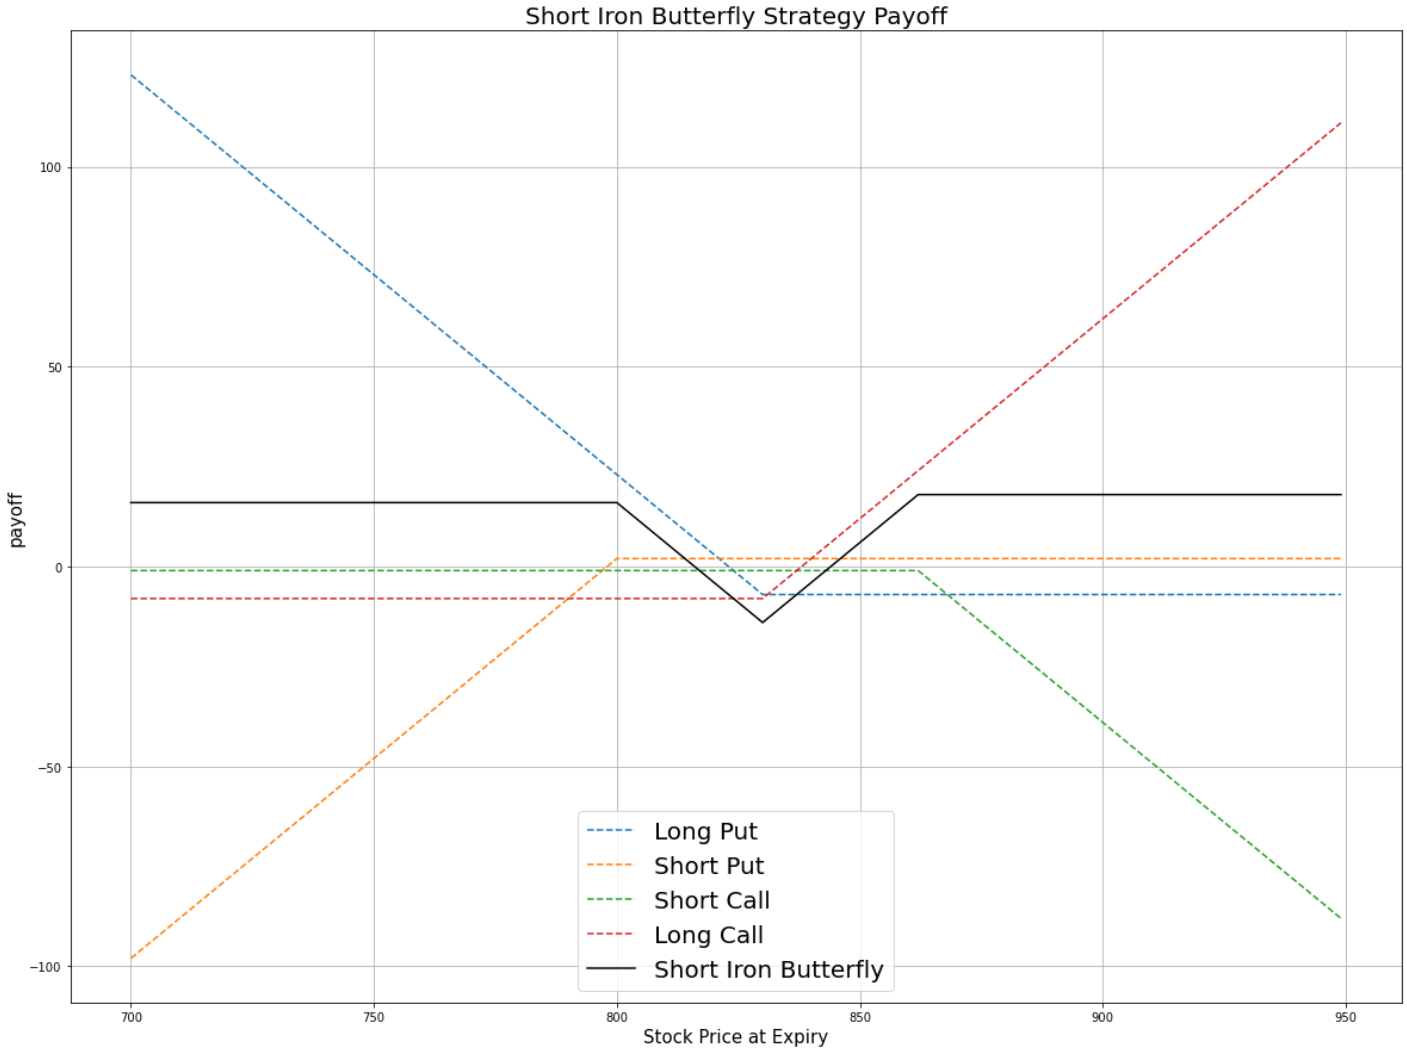
If the Option is American Option, there is a risk of early assignment on the sold contracts.

Short Call Butterfly

The short call butterfly is a limited-reward-limited-risk strategy. The payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{ATM}_T - P^{ATM}_T - C^{OTM}_0 - P^{OTM}_0 + C^{ATM}_0 + P^{ATM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{OTM} & = & \textrm{OTM call strike price}\\ & K^C_{ATM} & = & \textrm{ATM call strike price}\\ & K^P_{OTM} & = & \textrm{OTM put strike price}\\ & K^P_{ATM} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (credit received)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, C^{ATM}_0 + P^{ATM}_0 - C^{OTM}_0 - P^{OTM}_0. It occurs when the underlying price stays the same as when you opened the trade.

The maximum loss is K^C_{OTM} - K^C_{ATM} - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0. It occurs when the underlying price is below the OTM put strike price or above the OTM call strike price at expiration.

If the Option is American Option, there is a risk of early assignment on the sold contracts.

Example

The following table shows the price details of the assets in the algorithm:

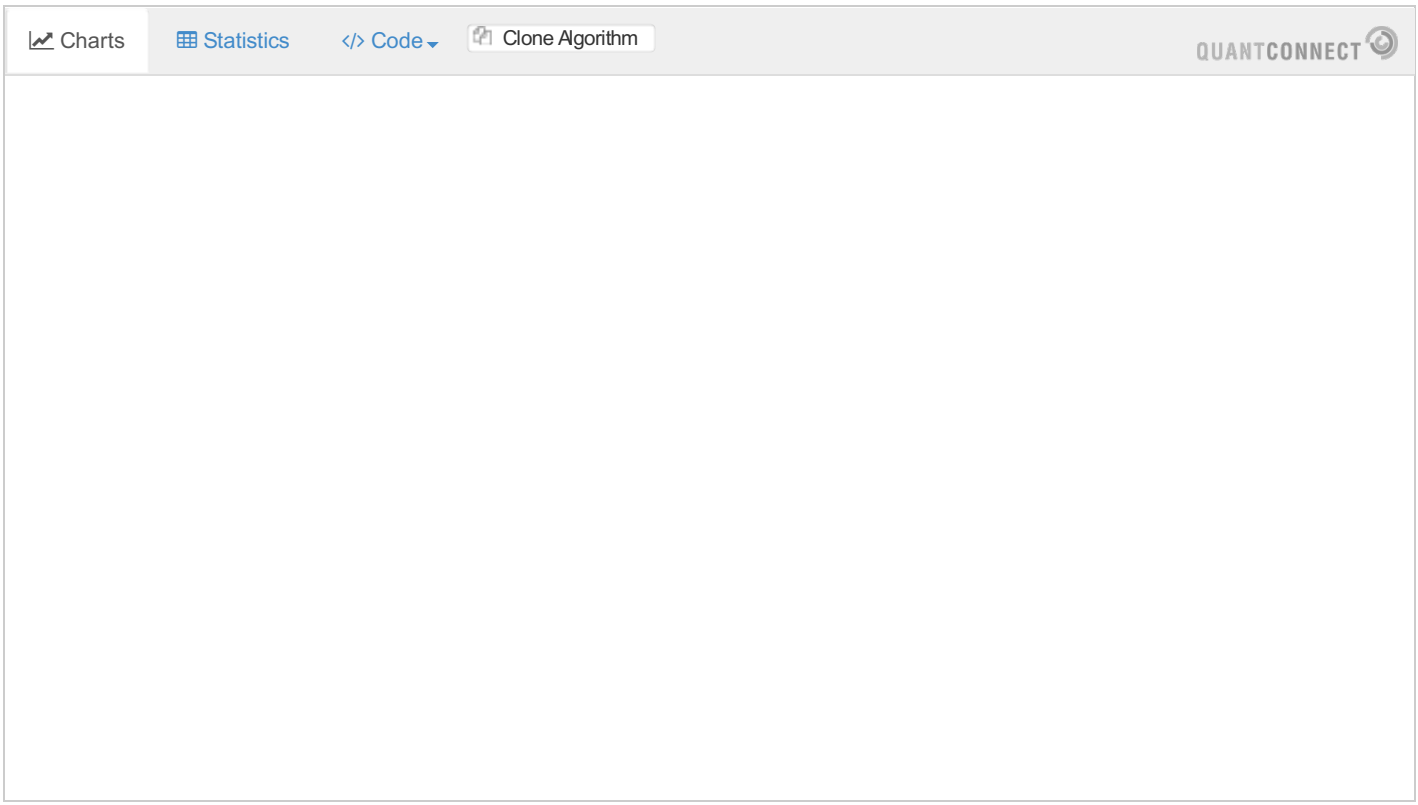
Asset	**Price ($)**	**Strike ($)**
OTM call	1.85	857.50
OTM put	2.75	810.00
ATM call	8.10	832.00
ATM put	7.40	832.00
Underlying Equity at expiration	851.20	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ & = & (851.20-857.50)^{+}\\ & = & 0\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ & = & (851.20-832.00)^{+}\\ & = & 19.20\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ & = & (832.00-851.20)^{+}\\ & = & 0\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ & = & (810.00-851.20)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{ATM}_T - P^{ATM}_T - C^{OTM}_0 - P^{OTM}_0 + C^{ATM}_0 + P^{ATM}_0)\times m - fee\\ & = & (0+0-19.20-0+8.10+7.40-1.85-2.75)\times100-1\times4\\ & = & -834 \end{array}$$

So, the strategy losses $834.

The following algorithm implements a short iron butterfly Option strategy:



Option Strategies

Iron Condor

Introduction

The **Iron Condor** is an Option strategy that consists of four contracts. All the contracts have the same underlying Equity and expiration, but the order of strike prices is A>B>C>D. The following table describes the strike prices of each contract:

Position	Strike
1 far-OTM call	A
1 near-OTM call	B, where B > underlying\ price
1 near-OTM put	C, where C < underlying\ price
1 far-OTM put	D, where C-D = A-B

The iron condor can be long or short.

Long Iron Condor

The long iron condor consists of selling a far OTM call, selling a far OTM put, buying a near OTM call, and buying a near OTM put. This strategy profits from a increase in price movement (implied volatility).

Short Iron Condor

The short iron condor consists of buying a far OTM call, buying a far OTM put, selling a near ATM call, and selling a near ATM put. This strategy profits from an decrease in price movement (implied volatility) and time decay since ATM options decay sharper.

Implementation

Follow these steps to implement the long iron condor strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
def Initialize(self) -> None:
    self.SetStartDate(2017, 2, 1)
    self.SetEndDate(2017, 3, 1)
    self.SetCash(500000)

    option = self.AddOption("GOOG")
    self.symbol = option.Symbol
    option.SetFilter(lambda universe:
        universe.IncludeWeeklys().Strikes(-15, 15).Expiration(0, 40))
```

2. In the `OnData` method, select the contracts in the strategy legs.

```
def OnData(self, slice: Slice) -> None:
    if self.Portfolio[self.symbol.Underlying].Invested:
        self.Liquidate()

    if self.Portfolio.Invested or not self.IsMarketOpen(self.symbol):
        return

    chain = slice.OptionChains.get(self.symbol)
    if not chain:
        return

    # Find put and call contracts with the farthest expiry
    expiry = max([x.Expiry for x in chain])
    chain = sorted([x for x in chain if x.Expiry == expiry], key = lambda x: x.Strike)

    put_contracts = [x for x in chain if x.Right == OptionRight.Put]
    call_contracts = [x for x in chain if x.Right == OptionRight.Call]

    if len(call_contracts) < 10 or len(put_contracts) < 10:
        return

    # Select the strikes in the strategy legs
    far_put = put_contracts[0].Strike
    near_put = put_contracts[10].Strike
    near_call = call_contracts[-10].Strike
    far_call = call_contracts[-1].Strike
```

3. In the `OnData` method, call the `OptionStrategies.IronCondor` method and then submit the order.

```
iron_condor = OptionStrategies.IronCondor(
    self.symbol,
    far_put,
    near_put,
    near_call,
    far_call,
    expiry)

self.Buy(iron_condor, 2)
```

Strategy Payoff

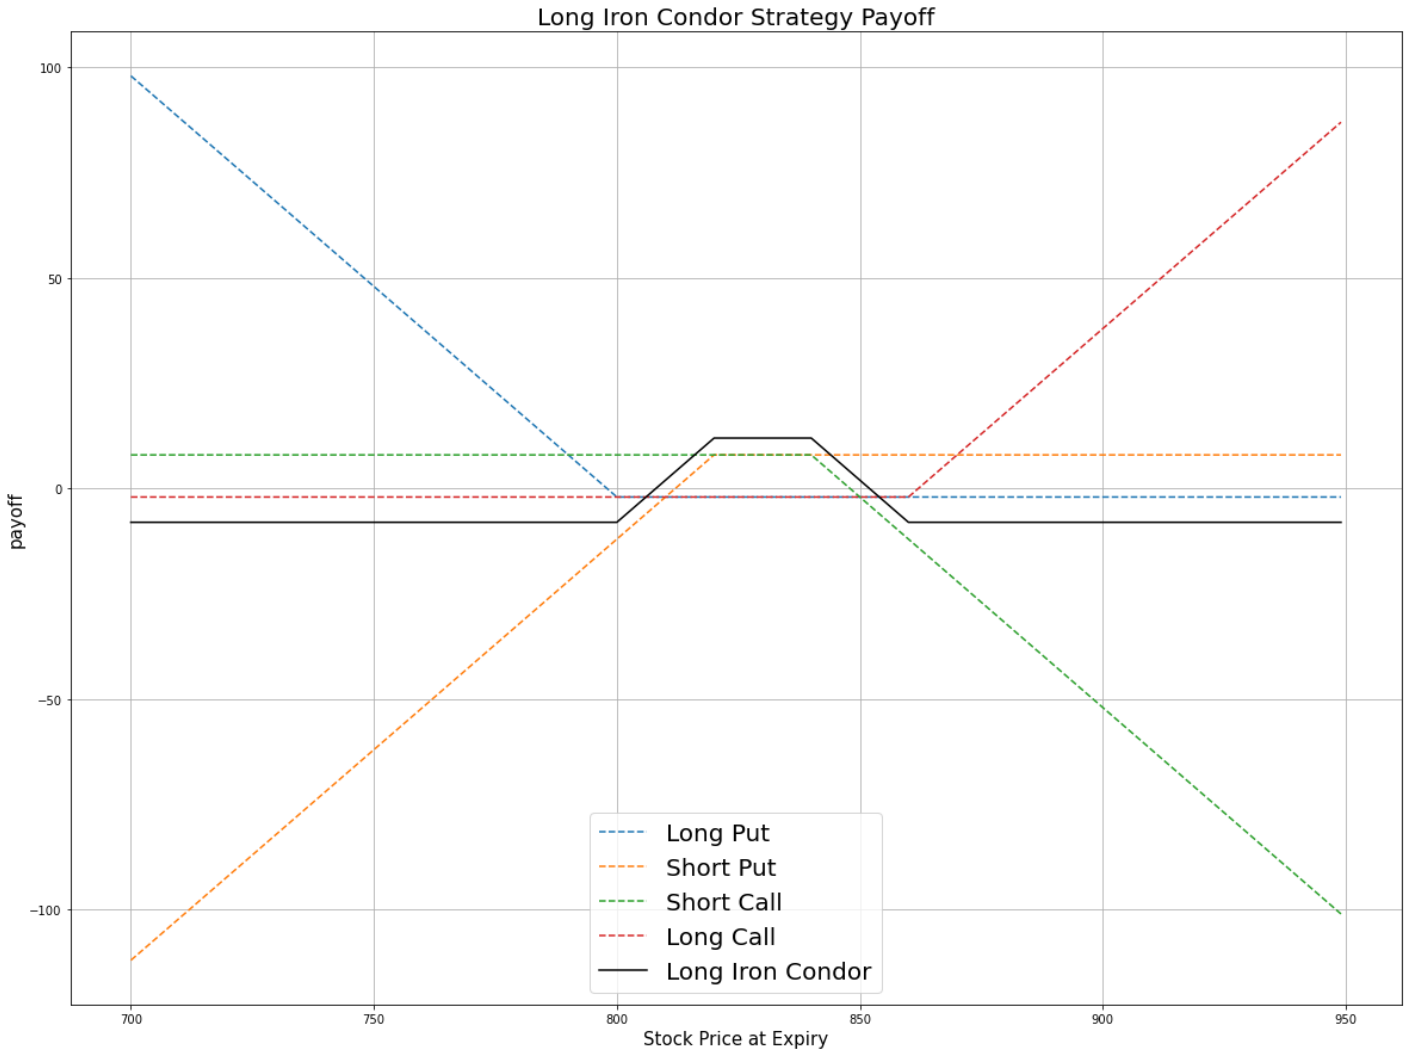
The iron condor can be long or short.

Long Iron Condor

This is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ P_T & = & (C^{near}_T + P^{near}_T - C^{far}_T - P^{far}_T - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & & & \\ C^{far}_T & = & \textrm{Far OTM call value at time T}\\ C^{near}_T & = & \textrm{Near OTM call value at time T}\\ P^{far}_T & = & \textrm{Far OTM put value at time T}\\ P^{near}_T & = & \textrm{Near ATM put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^C_{far} & = & \textrm{Far OTM call strike price}\\ K^C_{near} & = & \textrm{Near OTM call strike price}\\ K^P_{far} & = & \textrm{Far OTM put strike price}\\ K^P_{near} & = & \textrm{Near OTM put strike price}\\ P_T & = & \textrm{Payout total at time T}\\ C^{far}_0 & = & \textrm{Far OTM call value at position opening (credit received)}\\ C^{near}_0 & = & \textrm{Near OTM call value at position opening (debit paid)}\\ P^{far}_0 & = & \textrm{Far OTM put value at position opening (credit received)}\\ P^{near}_0 & = & \textrm{Near OTM put value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is K^C_{far} - K^C_{near} - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0, where K^P_{OTM} > S_T or S_T > K^C_{OTM}.

The maximum loss is the net debit paid: C^{far}_0 + P^{far}_0 - C^{near}_0 - P^{near}_0, where K^P_{OTM} < S_T < K^C_{OTM}.

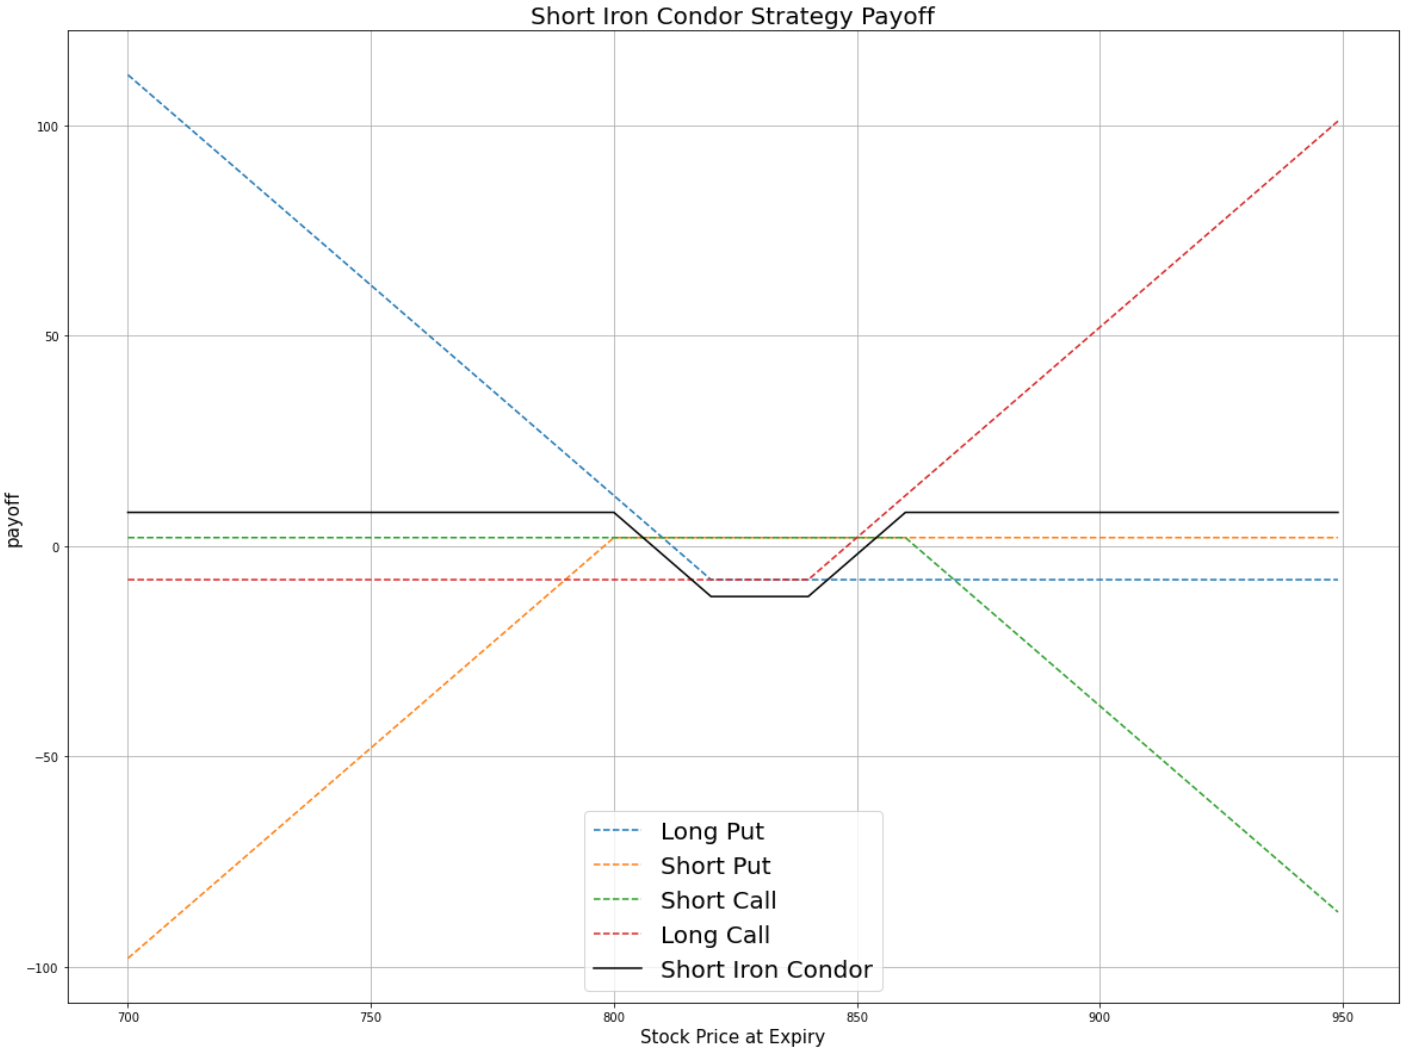
If the Option is American Option, there is a risk of early assignment on the sold contracts.

Short Iron Condor

This is a limited-reward-limited-risk strategy. The payoff is

\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ P_T & = & (C^{far}_T + P^{far}_T - C^{near}_T - P^{near}_T - C^{far}_0 - P^{far}_0 + C^{near}_0 + P^{near}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{far}_T & = & \textrm{Far OTM call value at time T}\\ & C^{near}_T & = & \textrm{Near OTM call value at time T}\\ & P^{far}_T & = & \textrm{Far OTM put value at time T}\\ & P^{near}_T & = & \textrm{Near ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{far} & = & \textrm{Far OTM call strike price}\\ & K^C_{near} & = & \textrm{Near OTM call strike price}\\ & K^P_{far} & = & \textrm{Far OTM put strike price}\\ & K^P_{near} & = & \textrm{Near OTM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{far}_0 & = & \textrm{Far OTM call value at position opening (credit received)}\\ & C^{near}_0 & = & \textrm{Near OTM call value at position opening (debit paid)}\\ & P^{far}_0 & = & \textrm{Far OTM put value at position opening (credit received)}\\ & P^{near}_0 & = & \textrm{Near OTM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}

The following chart shows the payoff at expiration:



The maximum profit is the net credit received after commission when opening the trade, where K^P_{OTM} < S_T < K^C_{OTM}.

The maximum loss is K^C_{far} - K^C_{near} + C^{near}_0 + P^{near}_0 - C^{far}_0 - P^{far}_0, where K^P_{OTM} > S_T or S_T > K^C_{OTM}.

If the Option is American Option, there is risk of early assignment on the sold contracts.

Example

The following table shows the price details of the assets in the algorithm:

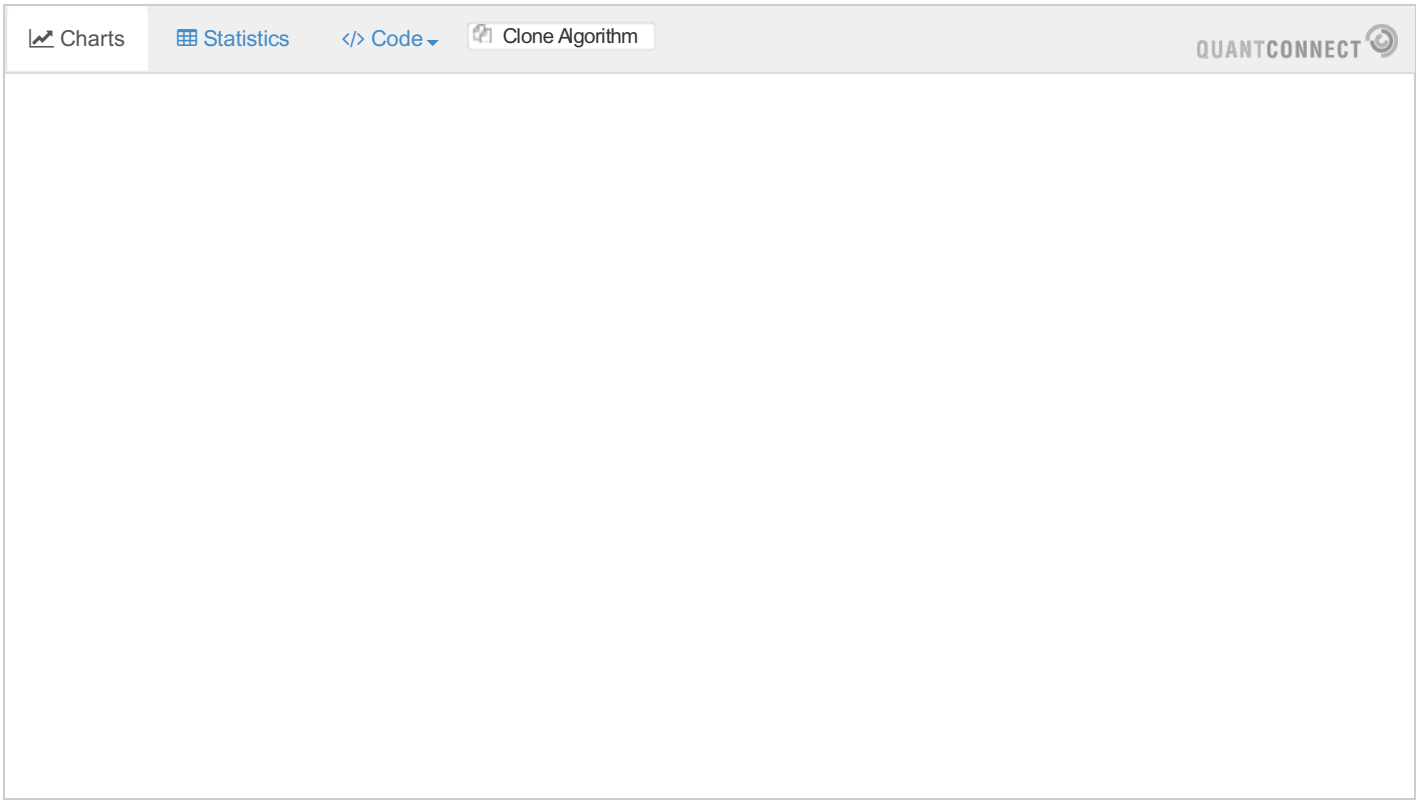
Asset	**Price ($)**	**Strike ($)**
Far-OTM call	1.85	857.50
Far-OTM put	2.75	810.00
Near-OTM call	1.35	855.00
Near-OTM put	2.15	815.00
Underlying Equity at expiration	851.20	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ & = & (851.20-857.50)^{+}\\ & = & 0\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ & = & (851.20-855.00)^{+}\\ & = & 0\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ & = & (815.00-851.20)^{+}\\ & = & 0\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ & = & (810.00-851.20)^{+}\\ & = & 0\\ P_T & = & (C^{near}_T + P^{near}_T - C^{far}_T - P^{far}_T - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0)\times m - fee\\ & = & (0+0-0-0+1.35+2.15-1.85-2.75)\times100-1\times4\\ & = & -114 \end{array}$$

So, the strategy losses $114.

The following algorithm implements a long iron condor Option strategy:



Demonstration Algorithm
IndexOptionIronCondorAlgorithm.py Python

Option Strategies

Protective Call

Introduction

A **Protective Call** consists of a short position in a stock and a long position in a call Option for the same amount of stock. Protective calls aim to hedge the short position of a stock with a long ATM or slightly OTM call Option. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, the Option contract becomes worthless but the short position acquires an unrealized gain. If the underlying price moves above the strike, you can exercise the Options contract and receive the underlying Equity, which closes your short position.

Implementation

Follow these steps to implement the protective call strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Options universe .

```
def Initialize(self) -> None:
    self.SetStartDate(2014, 1, 1)
    self.SetEndDate(2014, 3, 1)
    self.SetCash(100000)

    option = self.AddOption("IBM")
    self.symbol = option.Symbol
    self.call = None

    option.SetFilter(-3, 3, 0, 31)
```

2. In the `OnData` method, select the Option contract.

```
def OnData(self, slice: Slice) -> None:
    if self.call and self.Portfolio[self.call].Invested:
        return

    chain = slice.OptionChains.get(self.symbol)
    if not chain:
        return

    # Find ATM call with the farthest expiry
    expiry = max([x.Expiry for x in chain])
    call_contracts = sorted([x for x in chain
        if x.Right == OptionRight.Call and x.Expiry == expiry],
        key=lambda x: abs(chain.Underlying.Price - x.Strike))

    if not call_contracts:
        return

    atm_call = call_contracts[0]
```

3. In the `OnData` method, call the `OptionStrategies.ProtectiveCall` method and then submit the order.

```
protective_call = OptionStrategies.ProtectiveCall(self.symbol, atm_call.Strike, expiry)
self.Buy(protective_call, 1)

self.call = atm_call.Symbol
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False`. You can also provide a tag and order properties to the `Buy` method.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ P_T & = & (S_0 - S_T + C^{K}_T - C^{K}_0)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & C^{K}_T & = & \textrm{Call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C^{K}_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:

The maximum profit is $S_0 - C^{K}_0$, which occurs when the underlying price is 0.

The maximum loss is $S_0 - K - C^{K}_0$, which occurs when the underlying price is above the strike price.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	3.50	185.00
Underlying Equity at start of the trade	186.94	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ & = & (190.01 - 185)^{+}\\ & = & 5.01\\ P_T & = & (S_0 - S_T + C^{K}_T - C^{K}_0)\times m - fee\\ & = & (186.94 - 190.01 + 5.01 - 3.50)\times m - fee\\ & = & -1.56 \times 100 - 2\\ & = & -158 \end{array}$$

So, the strategy losses $158.

Option Strategies

Protective Put

Introduction

A **Protective Put** consists of buying a long position in a stock and a long position in put Options for the same amount of stock. Protective puts aim to hedge the long position of a stock with a long ATM or slightly OTM put Option. At any time for American Options or at expiration for European Options, if the stock moves above the strike price, the Option contract becomes worthless but the long stock position acquires an unrealized gain. If the underlying price moves below the strike, you can exercise the Options contract , which sells your underlying position at the put Option strike price.

Implementation

Follow these steps to implement the protective put strategy:

1. In the `Initialize` method, set the start date, end date, starting cash, and Options universe .

```
PY
def Initialize(self) -> None:
    self.SetStartDate(2014, 1, 1)
    self.SetEndDate(2014, 3, 1)
    self.SetCash(100000)

    option = self.AddOption("IBM")
    self.symbol = option.Symbol
    self.put = None

    option.SetFilter(-3, 3, 0, 31)
```

2. In the `OnData` method, select the Option contract.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.put and self.Portfolio[self.put].Invested:
        return

    chain = slice.OptionChains.get(self.symbol)
    if not chain:
        return

    # Find ATM put with the farthest expiry
    expiry = max([x.Expiry for x in chain])
    put_contracts = sorted([x for x in chain
        if x.Right == OptionRight.Put and x.Expiry == expiry],
        key=lambda x: abs(chain.Underlying.Price - x.Strike))

    if not put_contracts:
        return

    atm_put = put_contracts[0]
```

3. In the `OnData` method, call the `OptionStrategies.ProtectivePut` method and then submit the order.

```
protective_put = OptionStrategies.ProtectivePut(self.symbol, atm_put.Strike, expiry)
self.Buy(protective_put, 1)

self.put = atm_put.Symbol
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ P_T & = & (S_T - S_0 + P^{K}_T - P^{K}_0)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & P^{K}_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & P^{K}_0 & = & \textrm{Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:

The maximum profit is $S_T - S_0 - P^{K}_0$, which occurs when the underlying price is above the $S_0 + P^{K}_0$.

The maximum loss is P^{K}_0, which occurs when the underlying price drops.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Put	1.53	185.00
Underlying Equity at start of the trade	187.07	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ & = & (185 - 190.1)^{+}\\ & = & 0\\ P_T & = & (S_T - S_0 + P^{K}_T - P^{K}_0)\times m - fee\\ & = & (190.01 - 187.07 + 0 - 1.53)\times m - fee\\ & = & 1.41 \times 100 - 2\\ & = & 139 \end{array}$$

So, the strategy gains $139.

The following algorithm implements a protective put Option strategy:

Code
Clone Algorithm
QUANTCONNECT

Option Strategies

Protective Collar

Introduction

A **Protective Collar** is an Options strategy that consists of a covered call and a long put (protective put) with a lower strike price than the short call contract. In contrast to the covered call, the protective put component limits the drawdown of the strategy when the underlying price decreases too much.

Implementation

Follow these steps to implement the protective collar strategy:

1. In the `Initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```
PY
def Initialize(self) -> None:
    self.SetStartDate(2017, 4, 1)
    self.SetEndDate(2017, 4, 30)
    self.SetCash(100000)

    self.equity_symbol = self.AddEquity("GOOG").Symbol
    option = self.AddOption("GOOG", Resolution.Minute)
    self.option_symbol = option.Symbol
    option.SetFilter(-10, +10, timedelta(0), timedelta(30))
```

2. In the `OnData` method, select the Option contracts.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Select an expiry date
    expiry = sorted(chain, key = lambda x: x.Expiry)[-1].Expiry

    # Select the call and put contracts that expire on the selected date
    calls = [x for x in chain if x.Right == OptionRight.Call and x.Expiry == expiry]
    puts = [x for x in chain if x.Right == OptionRight.Put and x.Expiry == expiry]
    if not calls or not puts: return

    # Select the OTM contracts
    call = sorted(calls, key = lambda x: x.Strike)[-1]
    put = sorted(puts, key = lambda x: x.Strike)[0]
```

3. In the `OnData` method, submit the orders.

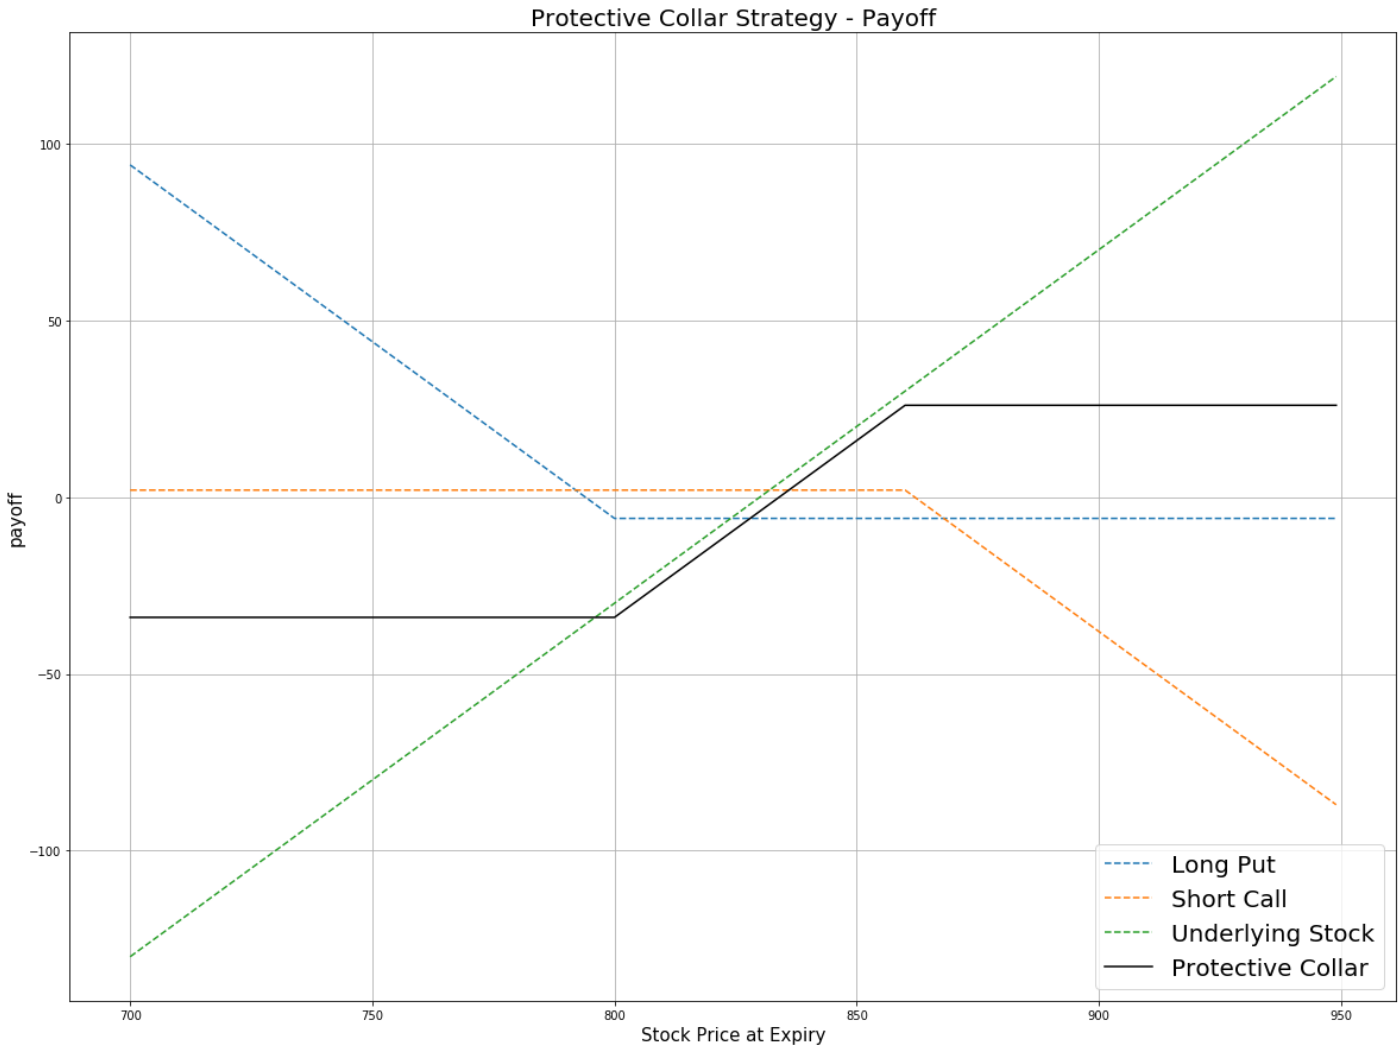
```
PY
self.Sell(call.Symbol, 1)          # Sell the OTM call
self.Buy(put.Symbol, 1)            # Buy the OTM put
self.Buy(self.equity_symbol, 100)  # Buy 100 shares of the underlying stock
```

Strategy Payoff

This is a limited-profit-limited-loss strategy. The payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K^{C})^{+}\\ P_T & = & (K^{P} - S_T)^{+}\\ Payoff_T & = & (S_T - S_0 - C_T + P_T + C_0 - P_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C_T & = & \textrm{Call value at time T}\\ & P_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{Call strike price}\\ & K^{P} & = & \textrm{Put strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & P_0 & = & \textrm{Put price when the trade opened (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K^{C} - S_T + C_0 - P_0$. It occurs when the underlying price is at or above the strike price of the call at expiration.

The maximum profit is $S_T - K^{P} + C_0 - P_0$. It occurs when the underlying price is at or below the strike price of the put at expiration.

If the Option is American Option, there is risk of early assignment on the sold contract.

Example

The following table shows the price details of the assets in the algorithm:

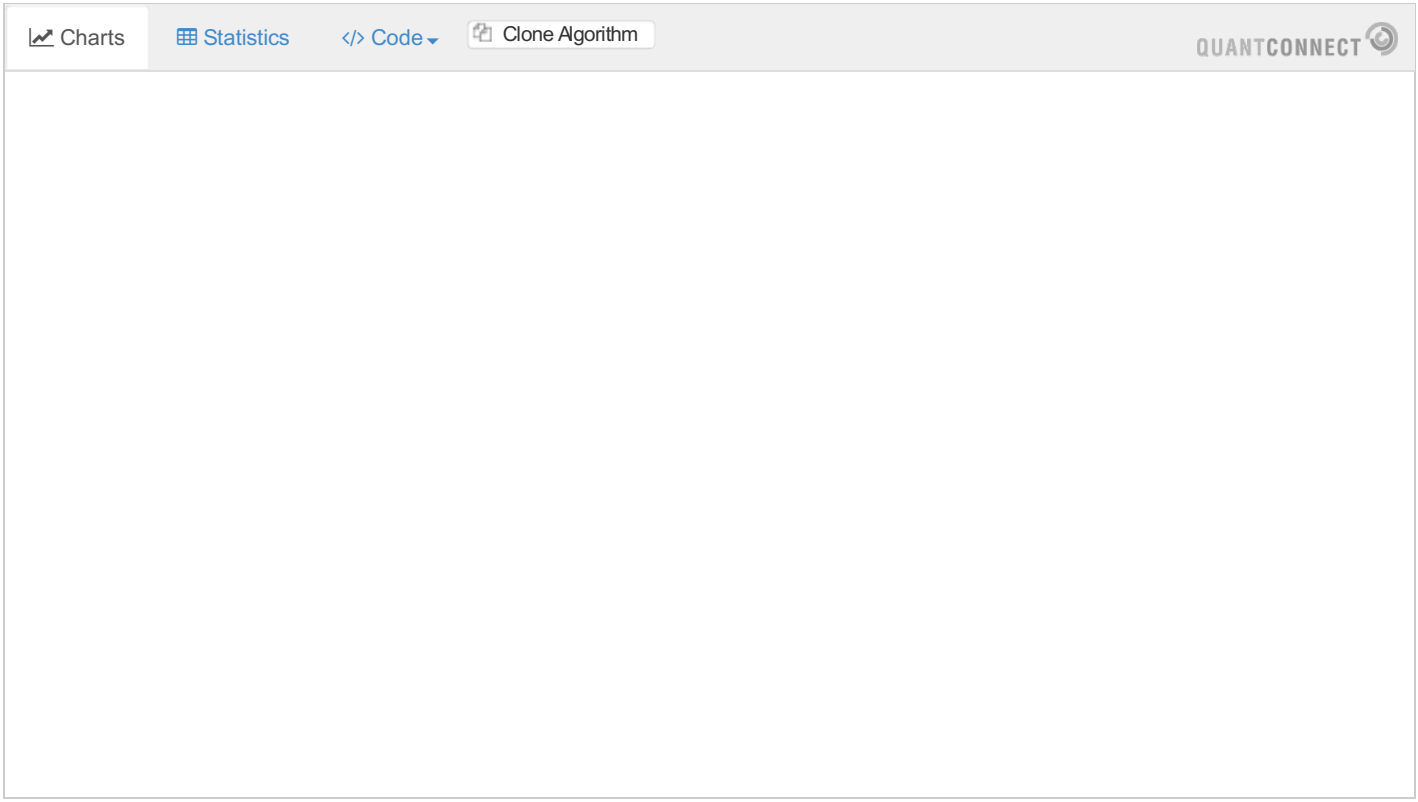
Asset	Price ($)	Strike ($)
Call	2.85	845.00
Put	6.00	822.50
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K^{C})^{+}\\ & = & (843.19-845.00)^{+}\\ & = & 0\\ P_T & = & (K^{P} - S_T)^{+}\\ & = & (822.50-843.19)^{+}\\ & = & 0\\ Payoff_T & = & (S_T - S_0 - C_T + P_T + C_0 - P_0)\times m - fee\\ & = & (843.19-833.17+0-0+2.85-6.00)\times100-1.00\times3\\ & = & 684\\ \end{array}$$

So, the strategy gains $684.

The following algorithm implements a protective collar Option strategy:



Option Strategies

Straddle

Introduction

Long Straddle is an Options trading strategy that consists of buying an ATM call and an ATM put, where both contracts have the same underlying asset, strike price, and expiration date. This strategy aims to profit from volatile movements in the underlying stock, either positive or negative.

Implementation

Follow these steps to implement the long straddle strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
PY
def Initialize(self) -> None:
    self.SetStartDate(2017, 4, 1)
    self.SetEndDate(2017, 6, 30)
    self.SetCash(100000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(-1, 1, timedelta(30), timedelta(60))
```

2. In the `OnData` method, select the expiration date and strike price of the contracts in the strategy legs.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Select an expiration date
    expiry = sorted(chain, key=lambda contract: contract.Expiry, reverse=True)[0].Expiry

    # Select the ATM strike price
    strikes = [contract.Strike for contract in chain if contract.Expiry == expiry]
    strike = sorted(strikes, key=lambda strike: abs(strike - chain.Underlying.Price))[0]
```

3. In the `OnData` method, call the `OptionStrategies.Straddle` method and then submit the order.

```
PY
option_strategy = OptionStrategies.Straddle(self.symbol, strike, expiry)
self.Buy(option_strategy, 1)
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

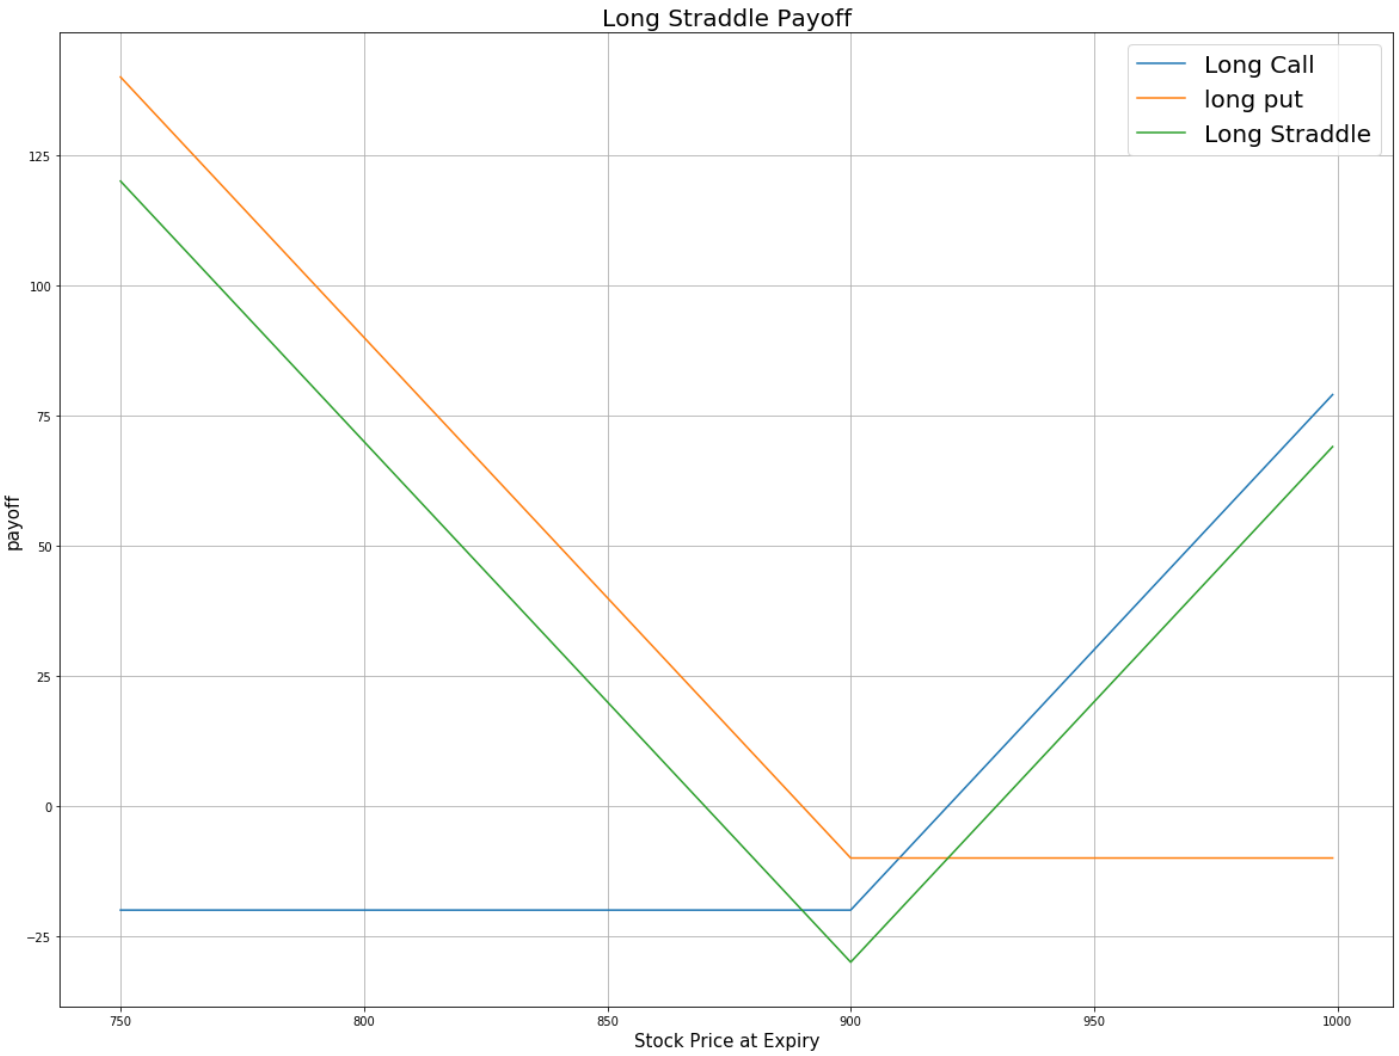
```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{ATM}_0 - P^{ATM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{ATM call strike price}\\ & K^{P} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is unlimited if the underlying price rises to infinity at expiration.

The maximum loss is the net debit paid, $C^{ATM}_0 + P^{ATM}_0$. It occurs when the underlying price is the same at expiration as it was when you opened the trade. In this case, both Options expire worthless.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (2017-05-20):

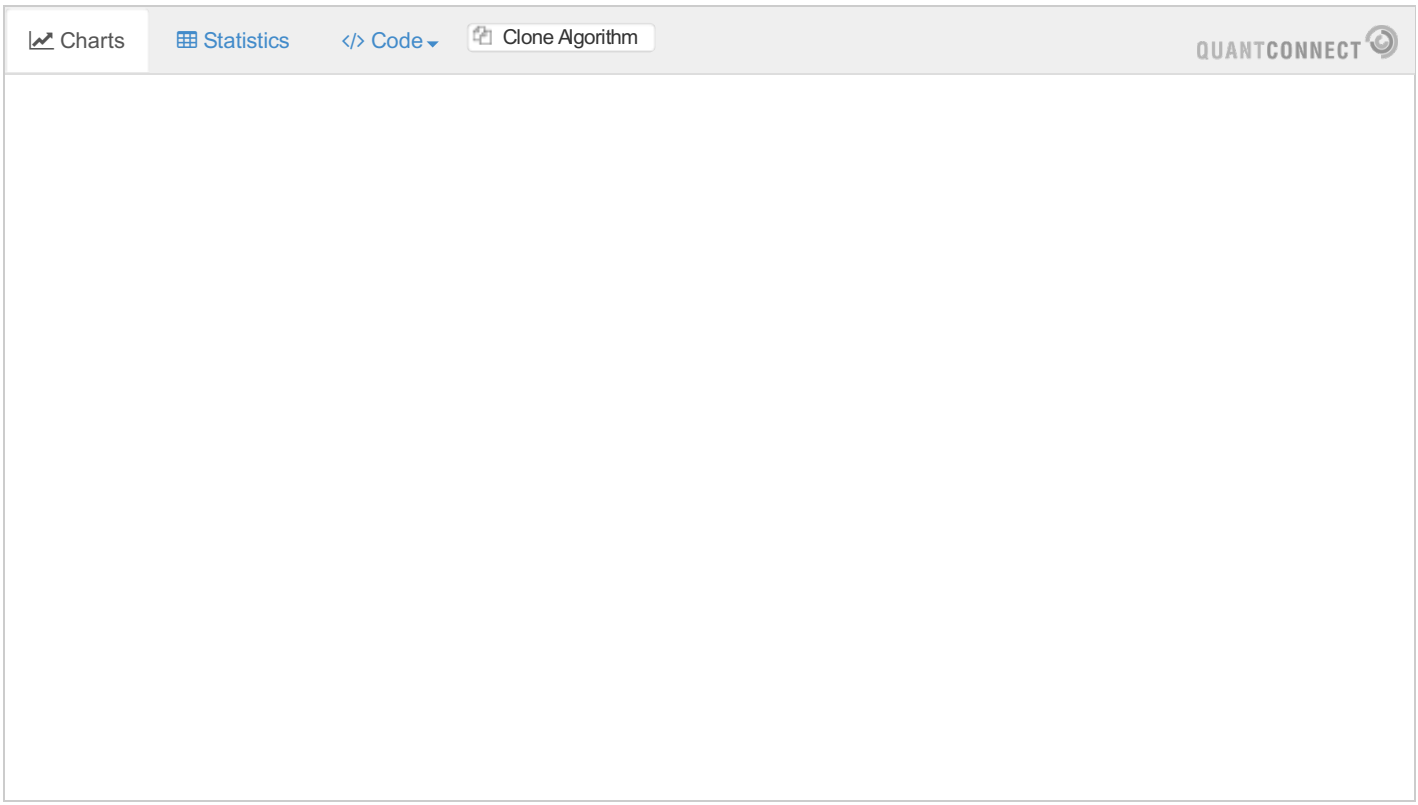
Asset	Price ($)	Strike ($)
Call	22.30	835.00
Put	23.90	835.00
Underlying Equity at expiration	934.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ & = & (934.01-835.00)^{+}\\ & = & 98.99\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ & = & (835.00-934.01)^{+}\\ & = & 0\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{ATM}_0 - P^{ATM}_0)\times m - fee\\ & = & (98.99+0-22.3-23.9)\times100-1.00\times2\\ & = & 5277 \end{array}$$

So, the strategy gains $5,277.

The following algorithm implements a long straddle Option strategy:



Option Strategies

Strangle

Introduction

Long Strangle is an Options trading strategy that consists of simultaneously buying an OTM put and an OTM call, where both contracts have the same underlying asset and expiration date. This strategy aims to profit from volatile movements in the underlying stock, either positive or negative.

Compared to a long straddle , the net debit of a long strangle is lower since OTM Options are cheaper. Additionally, the losing range of a long straddle is wider and the strike spread is wider.

Implementation

Follow these steps to implement the long strangle strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```py
def Initialize(self) -> None:
    self.SetStartDate(2017, 4, 1)
    self.SetEndDate(2017, 4, 30)
    self.SetCash(100000)

    option = self.AddOption("GOOG", Resolution.Minute)
    self.symbol = option.Symbol
    option.SetFilter(-5, 5, timedelta(0), timedelta(30))
```

2. In the `OnData` method, select the expiration date and strike prices of the contracts in the strategy legs.

```py
def OnData(self, slice: Slice) -> None:
    if self.Portfolio.Invested: return

    # Get the OptionChain
    chain = slice.OptionChains.get(self.symbol, None)
    if not chain: return

    # Select an expiration date
    expiry = sorted(chain, key=lambda contract: contract.Expiry, reverse=True)[0].Expiry

    # Select the OTM call strike
    strikes = [contract.Strike for contract in chain if contract.Expiry == expiry]
    call_strikes = [contract.Strike for contract in chain
        if contract.Expiry == expiry
        and contract.Right == OptionRight.Call
        and contract.Strike > chain.Underlying.Price]
    if len(call_strikes) == 0: return
    call_strike = min(call_strikes)

    # Select the OTM put strike
    put_strikes = [contract.Strike for contract in chain
        if contract.Expiry == expiry
        and contract.Right == OptionRight.Put
        and contract.Strike < chain.Underlying.Price]
    if len(put_strikes) == 0: return
    put_strike = max(put_strikes)
```

3. In the `OnData` method, call the `OptionStrategies.Strangle` method and then submit the order.

```
option_strategy = OptionStrategies.Strangle(self.symbol, call_strike, put_strike, expiry)
self.Buy(option_strategy, 1)
```

Option strategies synchronously execute by default. To asynchronously execute Option strategies, set the `asynchronous` argument to `False` . You can also provide a tag and order properties to the `Buy` method.

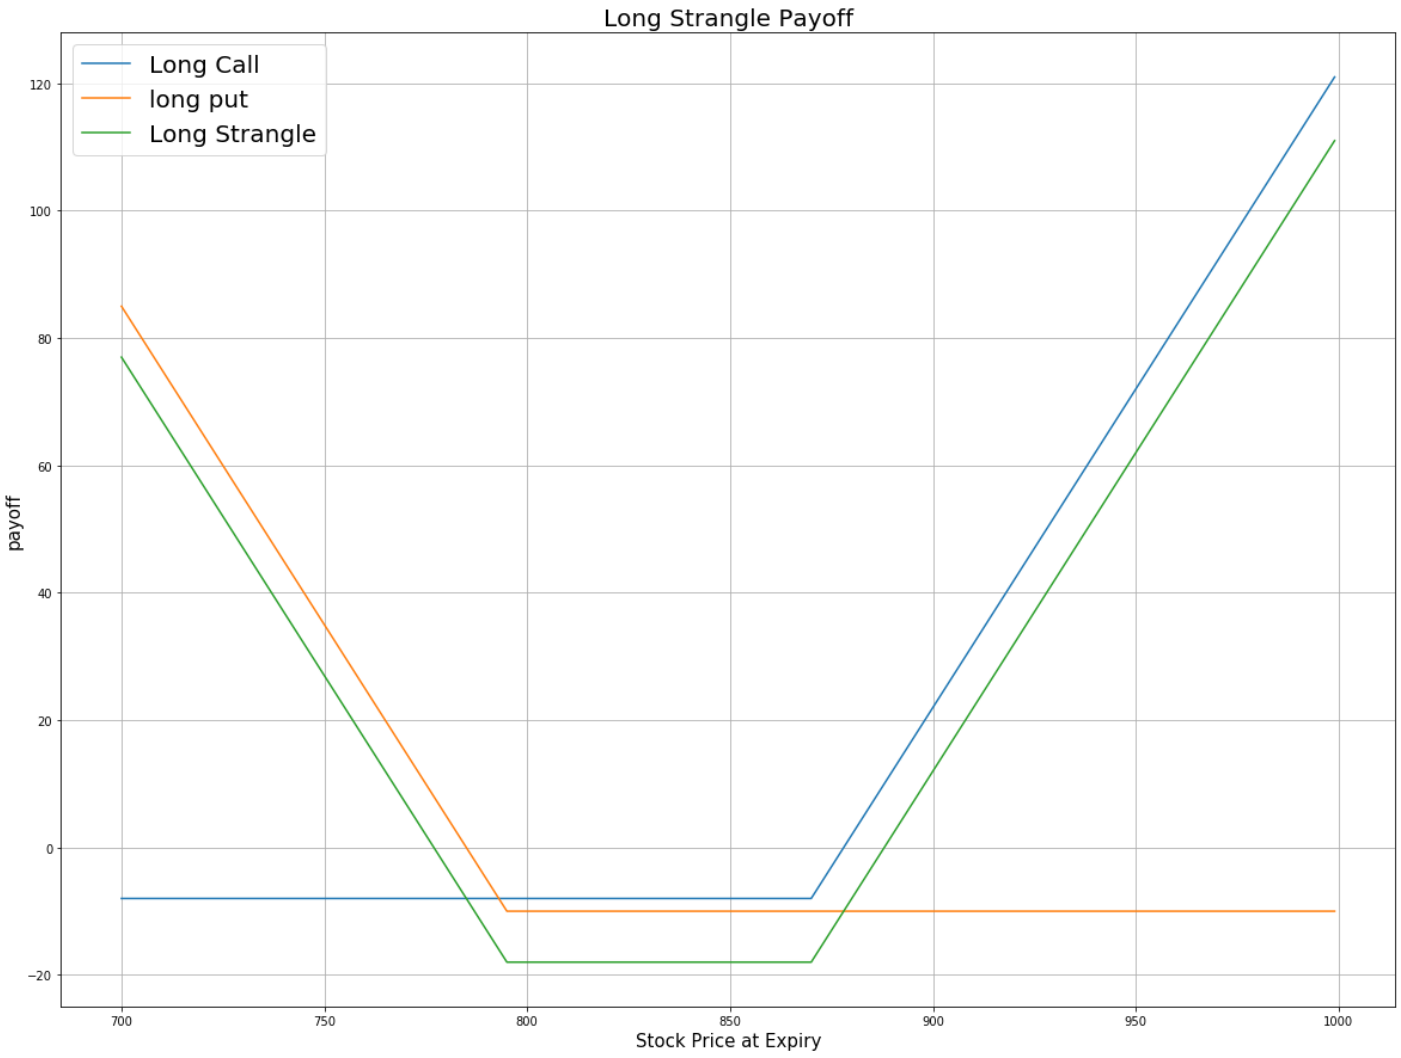
```
self.Buy(option_strategy, quantity, asynchronous, tag, order_properties)
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{OTM}_0 - P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{OTM call strike price}\\ & K^{P} & = & \textrm{OTM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is unlimited if the underlying price rises to infinity at expiration.

The maximum loss is the net debit paid, $C^{OTM}_0 + P^{OTM}_0$. It occurs when the underlying price at expiration is the same as when you opened the trade. In this case, both Options expire worthless.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (2017-04-22):

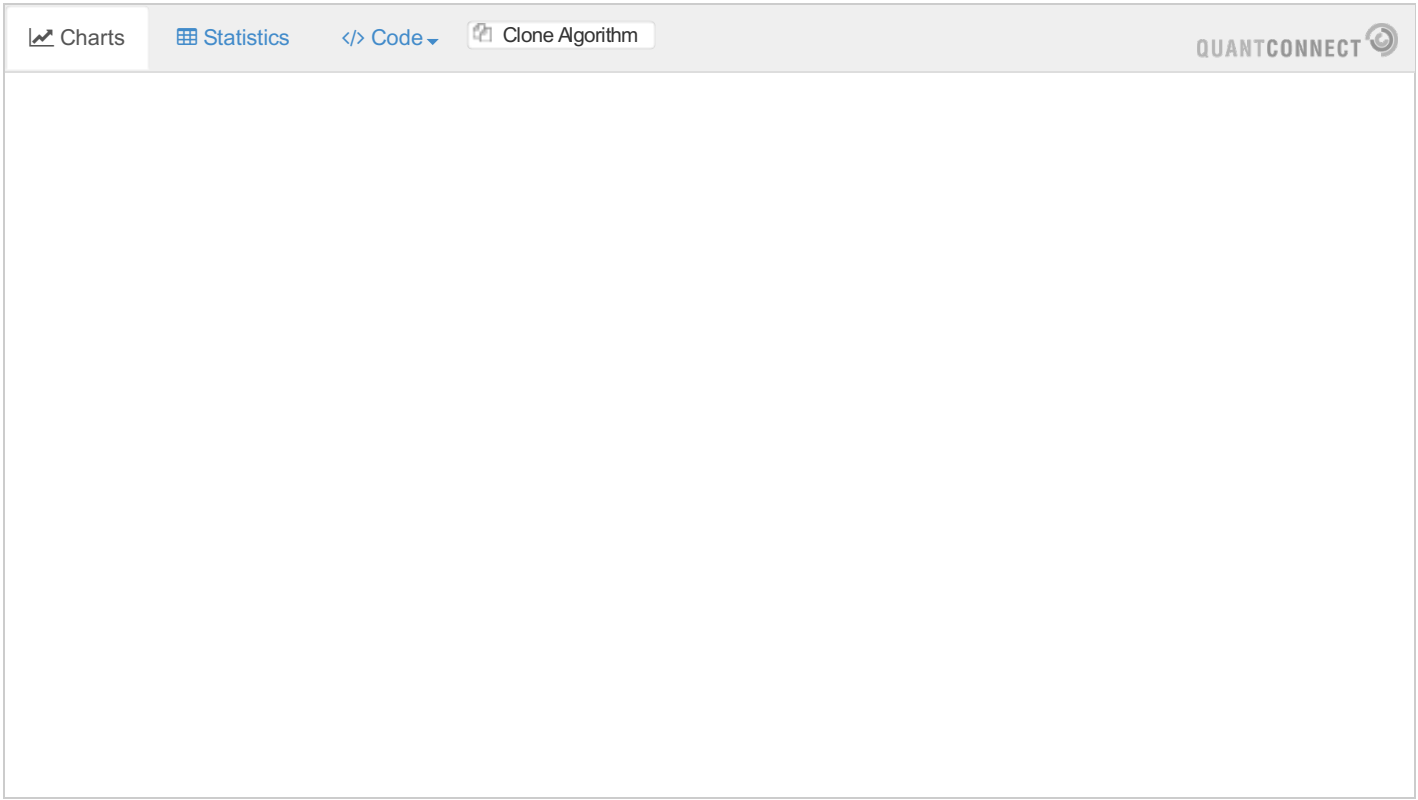
Asset	Price ($)	Strike ($)
Call	8.80	835.00
Put	9.50	832.50
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ & = & (832.50-843.19)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{OTM}_0 - P^{OTM}_0)\times m - fee\\ & = & (8.19+0-8.80-9.50)\times100-1.00\times2\\ & = & -1013 \end{array}$$

So, the strategy losses $1,013.

The following algorithm implements a long strangle Option strategy:



Trading and Orders

Order Properties

Introduction

Order properties enable you to customize how the brokerage executes your orders. The `DefaultOrderProperties` of your algorithm sets the order properties for all of your orders. To adjust the order properties of an order, you can change the `DefaultOrderProperties` or pass an order properties object to the order method.

Time In Force

The `TimeInForce` property determines how long an order should remain open if it doesn't fill. This property doesn't apply to market orders since they usually fill immediately. Time in force is useful to automatically cancel old trades. The following table describes the available TimeInForce options:

Member	Example	Description
`GoodTilCanceled`	`TimeInForce.GoodTilCanceled`	Order is valid until filled (default)
`Day`	`TimeInForce.Day`	Order is valid until filled or the market closes
`GoodTilDate(expiry: datetime)`	`GoodTilDate(datetime(2019, 6, 19, 12, 0, 0))`	Order is valid until filled or the specified expiration time

By default, orders remain open until they are canceled (`TimeInForce.GoodTilCanceled`). To update the value, set the `DefaultOrderProperties.TimeInForce` before you place an order or pass an `orderProperties` argument to the order method.

PY

```
# Set a Limit Order to be good until market close
self.DefaultOrderProperties.TimeInForce = TimeInForce.Day
self.LimitOrder("IBM", 100, 120)

# Set a Limit Order to be good until noon
order_properties = OrderProperties()
order_properties.TimeInForce = TimeInForce.GoodTilDate(datetime(2019, 6, 19, 12, 0, 0))
self.LimitOrder("IBM", 100, 120, orderProperties=order_properties)
```

If you trade a market that's open 24 hours a day with daily data, `TimeInForce.Day` won't work because the order cancels at the market close time but your algorithm receives daily data at midnight.

Market on open (MOO) and market on close (MOC) orders don't support the `GoodTilDate` time in force. If you submit a MOO or MOC order with the `GoodTilDate` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

The brokerage you use may not support all of the `TimeInForce` options. To see the options that your brokerage

supports, see the **Orders** section of the brokerage model documentation .

Brokerage-Specific Properties

Some brokerages support additional order properties so you can customize how your orders execute. Some examples include the following order properties:

- Financial Advisor group orders
- An `OutsideRegularTradingHours` property to let orders fill during pre-market and post-market trading hours
- A `PostOnly` property to force an order to only add liquidity to a market
- A `Hidden` property to make an order not show on the order book
- A `ReduceOnly` property to signal the order must only decrease your position size
- `FeeInBase` and `FeeInQuote` properties to set which currency you pay fees in for a Crypto trade

To view the order properties your brokerage supports, see the **Orders** section of the brokerage model documentation .

Tags

You can tag orders to aid your strategy development. Tags can be any string of up to 100 characters. Tags aren't part of the `OrderProperties` object, but they are a property of the `Order` class you can set. To set an order tag, pass it as an argument when you create the order or use the order update methods.

```py
 # Tag an order on creation
ticket = self.LimitOrder("SPY", 100, 221.05, "Original tag")

# Update the tag with UpdateTag
ticket.UpdateTag("Updated tag")

# Update the tag with UpdateOrderFields
update_settings = UpdateOrderFields()
update_settings.Tag = "Another tag"
ticket.Update(update_settings)
```

Trading and Orders

Order Events

Introduction

An `OrderEvent` object represents an update to the state of an order. As the state of your orders change, we notify your algorithm with `OrderEvent` objects through the `OnOrderEvent` and `OnAssignmentOrderEvent` event handlers.

Track Order Events

Each order generates events over its life as its status changes. Your algorithm receives these events through the `OnOrderEvent` and `OnAssignmentOrderEvent` methods. The `OnOrderEvent` event handler receives all order events. The `OnAssignmentOrderEvent` receives order events for Option assignments. The event handlers receive an `OrderEvent` object, which contains information about the order status.

```
PY
def OnOrderEvent(self, orderEvent: OrderEvent) -> None:
    order = self.Transactions.GetOrderById(orderEvent.OrderId)
    if orderEvent.Status == OrderStatus.Filled:
        self.Debug(f"{self.Time}: {order.Type}: {orderEvent}")

def OnAssignmentOrderEvent(self, assignmentEvent: OrderEvent) -> None:
    self.Log(str(assignmentEvent))
```

To get a list of all `OrderEvent` objects for an order, call the `OrderEvents` method of the order ticket .

```
PY
order_events = order_ticket.OrderEvents()
```

If you don't have the order ticket, get the order ticket from the TransactionManager .

Order States

Orders can have any of the following states:

Event Attributes

The `OnOrderEvent` and `OnAssignmentOrderEvent` event handlers in your algorithm receive `OrderEvent` objects, which have the following attributes:

Trading and Orders

Order Errors

Introduction

If an error occurs with one of your orders, LEAN logs the error message and stops executing.

Types of Order Errors

Errors can occur when you place orders or after you place them.

Errors at Order Submission

The following errors can occur when you submit an order:

- `AlgorithmWarmingUp`
- `BrokerageFailedToSubmitOrder`
- `BrokerageModelRefusedToSubmitOrder`
- `ConversionRateZero`
- `ExceededMaximumOrders`
- `ExceedsShortableQuantity`
- `ExchangeNotOpen`
- `ForexBaseAndQuoteCurrenciesRequired`
- `ForexConversionRateZero`
- `InsufficientBuyingPower`
- `MarketOnCloseOrderTooLate`
- `MissingSecurity`
- `NonExercisableSecurity`
- `NonTradableSecurity`
- `OrderAlreadyExisits`
- `OrderQuantityLessThanLotSize`
- `OrderQuantityZero`
- `PreOrderChecksError`
- `QuoteCurrencyRequired`
- `SecurityHasNoData`
- `UnsupportedRequestType`
- `EuropeanOptionNotExpiredOnExercise`

Errors After Order Submission

The following errors can occur for active orders:

- `BrokerageFailedToUpdateOrder`
- `BrokerageModelRefusedToUpdateOrder`

- `InvalidNewOrderStatus`
- `InvalidOrderStatus`
- `InvalidRequest`
- `RequestCanceled`
- `UnableToFindOrder`

Common Errors

There are a few common order errors you may experience.

Why is my order converted to a market on open order?

If you place a market order when the market is closed, LEAN automatically converts the order into market on open order. This most commonly happens when you use daily or hourly data, which your algorithm can receive when the market is closed. Your algorithm receives daily bars at midnight and receives the last hourly bar of each day at 4 PM Eastern Time (ET). To avoid LEAN from converting your market order to market on open orders, submit your market orders when the market is open. To check if the market is open, call the `IsMarketOpen` method.

```
PY
if self.IsMarketOpen(self.symbol):
    self.MarketOrder(self.symbol, quantity)
```

Why am I seeing the "stale price" warning?

Stale fills occur when you fill an order with price data that is timestamped an hour or more into the past. Stale fills usually only occur if you trade illiquid assets or if your algorithm uses daily data but you trade intraday with Scheduled Events. If your order is filled with stale data, the fill price may not be realistic. The pre-built fill models can only fill market orders with stale data. To adjust the length of time that needs to pass before an order is considered stale, set the `StalePriceTimeSpan` setting.

```
PY
self.Settings.StalePriceTimeSpan = timedelta(minutes=10)
```

Why do I get "Backtest Handled Error: The security with symbol '/ES' is marked as non-tradable"?

This error occurs when you place an order for a continuous Futures contract, which isn't a tradable security. To fix the issue, place the order for a specific Futures contract. To access the currently selected contract in the continuous contract series, use the `Mapped` property of the `Future` object.

Error Code Reference

The `OrderError` enumeration has the following members:

Order Response Error Reference

The following sections explain why each `OrderResponseErrorCode` occurs and how to avoid it.

None

The `OrderResponseErrorCode.None` (0) error means there is no order response error.

Processing Error

The `OrderResponseErrorCode.ProcessingError` (-1) error occurs in the following situations:

- When you submit a new order, but LEAN throws an exception while checking if you have sufficient buying power for the order.
- When you try to update or cancel an order, but LEAN throws an exception.

To investigate this order response error further, see the `HandleSubmitOrderRequest` , `UpdateOrder` , and `CancelOrder` methods of the BrokerageTransactionHandler in the LEAN GitHub repository.

Order Already Exists

The `OrderResponseErrorCode.OrderAlreadyExists` (-2) error occurs when you submit a new order but you already have an open order or a completed order with the same order ID. This order response error usually comes from a concurrency issue.

To avoid this order response, don't place two asynchronous orders at the same time. GitHub Issue #6736 may address the underlying problem.

Insufficient Buying Power

The `OrderResponseErrorCode.InsufficientBuyingPower` (-3) error occurs when you place an order but the buying power model determines you can't afford it.

This error commonly occurs when you place a market on open order with daily data. If you place the order with `SetHoldings` or use `CalculateOrderQuantity` to determine the order quantity, LEAN calculates the order quantity based on the market close price. If the open price on the following day makes your order more expensive, then you may have insufficient buying power. To avoid the order response error in this case, either use intraday data and place trades when the market is open or adjust your buying power buffer .

```
PY
self.Settings.FreePortfolioValuePercentage = 0.05
```

Brokerage Model Refused to Submit Order

The `OrderResponseErrorCode.BrokerageModelRefusedToSubmitOrder` (-4) error occurs when you place an order but the brokerage model determines it's invalid. The brokerage model usually checks your order meets the following requirements before sending it to the brokerage:

- Supported security types
- Supported order types and their respective requirements
- Supported time in force options
- The order size is larger than the minimum order size

Each brokerage model can have additional order requirements that the brokerage declares. To avoid this order response error, see the **Orders** section of the brokerage model documentation .

To investigate this order response error further, see the `CanSubmitOrder` method definition of your brokerage model .

This order response error occurs when the `CanSubmitOrder` method returns `False` .

Brokerage Failed to Submit Order

The `OrderResponseErrorCode.BrokerageFailedToSubmitOrder` (-5) error occurs when you place an order but the brokerage implementation fails to submit the order to your brokerage.

To investigate this order response error further, see the `PlaceOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when the `PlaceOrder` method throws an error or returns `false` .

Brokerage Failed to Update Order

The `OrderResponseErrorCode.BrokerageFailedToUpdateOrder` (-6) error occurs when you try to update an order but the brokerage implementation fails to submit the order update request to your brokerage.

To avoid this order response error, see the **Orders** section of the brokerage model documentation .

To investigate this order response error further, see the `UpdateOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when the `UpdateOrder` method throws an error or returns `false` .

Brokerage Failed to Cancel Order

The `OrderResponseErrorCode.BrokerageFailedToCancelOrder` (-8) error occurs when you try to cancel an order but the brokerage implementation fails to submit the cancel request to your brokerage.

To investigate this order response error further, see the `CancelOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when `CancelOrder` method throws an error or returns `false` .

Invalid Order Status

The `OrderResponseErrorCode.InvalidOrderStatus` (-9) error occurs when you try to update or cancel an order but the order is already complete. An order is complete if it has `OrderStatus.Filled` , `OrderStatus.Canceled` , or `OrderStatus.Invalid` .

To avoid this order response error, check `Status` of an order ticket or order event before you update or cancel the order.

```
PY
if not OrderExtensions.IsClosed(order_ticket.Status):
    order_ticket.Cancel()
```

Unable to Find Order

The `OrderResponseErrorCode.UnableToFindOrder` (-10) error occurs when you try to place, update, or cancel an order, but the `BrokerageTransactionHandler` doesn't have a record of the order ID.

To investigate this order response error further, see BrokerageTransactionHandler.cs in the LEAN GitHub repository. This order response error occurs when the `BrokerageTransactionHandler` can't find the order ID in it's

`_completeOrders` or `_completeOrderTickets` dictionaries.

Order Quantity Zero

The `OrderResponseErrorCode.OrderQuantityZero` (-11) error occurs when you place an order that has zero quantity or when you update an order to have a zero quantity. This error commonly occurs if you use the SetHoldings method but the portfolio weight you provide to the method is too small to translate into a non-zero order quantity.

To avoid this order response error, check if the quantity of the order is non-zero before you place the order. If you use the `SetHoldings` method, replace it with a combination of the CalculateOrderQuantity and MarketOrder methods.

```
PY
quantity = self.CalculateOrderQuantity(self.symbol, 0.05)
if quantity:
    self.MarketOrder(self.symbol, quantity)
```

Unsupported Request Type

The `OrderResponseErrorCode.UnsupportedRequestType` (-12) error occurs in the following situations:

- When you try to exercise an Option contract for which you hold a short position
- When you try to exercise more Option contracts than you hold

To avoid this order response error, check the quantity of your holdings before you try to exercise an Option contract.

```
PY
holding_quantity = self.Portfolio[self.contract_symbol].Quantity
if holding_quantity > 0:
    self.ExerciseOption(self.contract_symbol, max(holding_quantity, exercise_quantity))
```

Missing Security

The `OrderResponseErrorCode.MissingSecurity` (-14) error occurs when you place an order for a security but you don't have a subscription for the security in your algorithm.

To avoid this order response error, create a subscription for each security you want to trade. To create subscriptions, see the Requesting Data page of the documentation for each asset class .

Exchange Not Open

The `OrderResponseErrorCode.ExchangeNotOpen` (-15) error occurs in the following situations:

- When you try to exercise an Option while the exchange is not open

  To avoid the order response error in this case, check if the exchange is open before you exercise an Option contract.

  ```
  PY
  if self.IsMarketOpen(self.contract_symbol):
      self.ExerciseOption(self.contract_symbol, quantity)
  ```

- When you try to place a market on open order for a Futures contract or a Future Option contract

Security Price Zero

The `OrderResponseErrorCode.SecurityPriceZero` (-16) error occurs when you place an order or exercise an Option contract while the security price is 0. The security price can be 0 for the following reasons:

- The data is missing

  Investigate if it's a data issue. If it is a data issue, report it .

- The algorithm hasn't received data for the security yet

  If you subscribe to a security and place an order for the security in the same time step , you'll get this error. To avoid this order response error, initialize the security price with the last known price.

  ```
  self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel,
  FuncSecuritySeeder(self.GetLastKnownPrices)))
  ```
  PY

Forex Base and Quote Currencies Required

The `OrderResponseErrorCode.ForexBaseAndQuoteCurrenciesRequired` (-17) error occurs when you place a trade for a Forex or Crypto pair but you don't have the base currency and quote currency in your cash book . This error should never occur. If it does, create a bug report.

Forex Conversion Rate Zero

The `OrderResponseErrorCode.ForexConversionRateZero` (-18) error occurs when you place a trade for a Forex or Crypto pair and LEAN can't convert the value of the base currency to your account currency. This error usually indicates a lack of data. Investigate the data and if there is some missing, report it .

Security Has No Data

The `OrderResponseErrorCode.SecurityHasNoData` (-19) error occurs when you place an order for a security before your algorithm receives any data for it. If you subscribe to a security and place an order for the security in the same time step , you'll get this error. To avoid this order response error, initialize the security price with the last known price.

```
self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))
```
PY

Exceeded Maximum Orders

The `OrderResponseErrorCode.ExceededMaximumOrders` (-20) error occurs when exceed your order quota in a backtest. The number of orders you can place in a single backtest depends on the tier of your organization . The following table shows the number of orders you can place on each tier:

Tier	Orders Quota
Free	10K
Quant Researcher	10M
Team	Unlimited
Trading Firm	Unlimited
Institution	Unlimited

To avoid this order response error, reduce the number of orders in your backtest or upgrade your organization .

Market on Close Order Too Late

The `OrderResponseErrorCode.MarketOnCloseOrderTooLate` (-21) error occurs when you try to place a market on close (MOC) order too early in the trading day.

To avoid this order response error, place the MOC order closer to the market close or adjust the submission time buffer. By default, you must place MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.SubmissionTimeBuffer` property.

```
MarketOnCloseOrder.SubmissionTimeBuffer = timedelta(minutes=10)
```

Invalid Request

The `OrderResponseErrorCode.InvalidRequest` (-22) error occurs when you try to cancel an order multiple times.

To avoid this order response error, only try to cancel an order one time.

Request Canceled

The `OrderResponseErrorCode.RequestCanceled` (-23) error occurs when you try to cancel an order multiple times.

To avoid this order response error, only try to cancel an order one time.

Algorithm Warming Up

The `OrderResponseErrorCode.AlgorithmWarmingUp` (-24) error occurs in the following situations:

- When you try to place, update, or cancel an order during the warm-up period
- When the Option assignment simulator assigns you to an Option during the warm-up period

To avoid this order response error, only manage orders after the warm-up period ends. To avoid trading during the warm-up period, add an `IsWarmingUp` guard to the top of the `OnData` method.

```
if self.IsWarmingUp: return
```

Brokerage Model Refused to Update Order

The `OrderResponseErrorCode.BrokerageModelRefusedToUpdateOrder` (-25) error occurs in backtests when you try to update an order in a way that the brokerage model doesn't support.

To avoid this issue, see the **Orders** section of the brokerage model documentation to check its order requirements.

To investigate this order response error further, see the `CanUpdateOrder` method definition of your brokerage model .

Quote Currency Required

The `OrderResponseErrorCode.QuoteCurrencyRequired` (-26) error occurs when you place an order for a Forex or Crypto pair and don't have the quote currency of the pair in your cash book . This error should never occur. If it does, create a bug report.

Conversion Rate Zero

The `OrderResponseErrorCode.ConversionRateZero` (-27) error occurs when you place an order for a Forex or Crypto pair and LEAN can't convert the value of the quote currency in the pair to your account currency. This order response error usually indicates a lack of data. Investigate the data and if there is data missing, report it .

Non-Tradable Security

The `OrderResponseErrorCode.NonTradableSecurity` (-28) error occurs when you place an order for a security that's not tradable . To avoid this order response error, check if a security is tradable before you trade it.

```py
if self.Securities[self.symbol].IsTradable:
    self.MarketOrder(self.symbol, quantity)
```

Non-Exercisable Security

The `OrderResponseErrorCode.NonExercisableSecurity` (-29) error occurs when you call the ExerciseOption method with a `Symbol` that doesn't reference an Option contract.

Order Quantity Less Than Lot Size

The `OrderResponseErrorCode.OrderQuantityLessThanLotSize` (-30) error occurs when you place an order with a quantity that's less than the lot size of the security.

To avoid this order response error, check if the order quantity is greater than or equal to the security lot size before you place an order.

```py
lot_size = self.Securities[self.symbol].SymbolProperties.LotSize
if quantity >= lot_size:
    self.MarketOrder(self.symbol, quantity)
```

Exceeds Shortable Quantity

The `OrderResponseErrorCode.ExceedsShortableQuantity` (-31) error occurs when you place an order to short a security but the shortable provider of the brokerage model states there isn't enough shares to borrow. For a full

example of this error, clone and run this backtest .

To avoid this order response error, check if there are enough shares available before you place an order to short a security.

```
available_to_borrow = self.BrokerageModel.GetShortableProvider().ShortableQuantity(self.symbol, self.Time)
if available_to_borrow == None or quantity_to_borrow <= available_to_borrow:
    self.MarketOrder(self.symbol, -quantity_to_borrow)
```

PY

Invalid New Order Status

The `OrderResponseErrorCode.InvalidNewOrderStatus` (-32) error occurs in live trading when you try to update or cancel an order while it still has `OrderStatus.New` status.

To avoid this order response error, check the `Status` property of the order ticket or order event before you update or cancel an order.

```
if self.order_ticket.Status != OrderStatus.New:
    self.order_ticket.Cancel()
```

PY

European Option Not Expired on Exercise

The `OrderResponseErrorCode.EuropeanOptionNotExpiredOnExercise` (-33) error occurs when you try to exercise a European Option contract before its expiry date.

To avoid this order response error, check the type and expiry date of the contract before you exercise it.

```
if (self.contract_symbol.ID.OptionStyle == OptionStyle.European && self.contract_symbol.ID.Date ==
self.Time.Date)
{
    self.ExerciseOption(self.contract_symbol, quantity);
}
```

PY

Trading and Orders

Trade Statistics

Introduction

The `TradeBuilder` tracks the trades of your algorithm and calculates some statistics. You can adjust how it defines a trade and how it matches offsetting order fills.

Set Trade Builder

To set the `TradeBuilder` , in the `Initialize` method, call the `SetTradeBuilder` method.

```
self.SetTradeBuilder(TradeBuilder(groupingMethod, matchingMethod))
```

The following table describes the arguments the `TradeBuilder` constructor accepts:

Argument	Data Type	Description	Default Value
`groupingMethod`	`FillGroupingMethod`	The method used to group order fills into trades	
`matchingMethod`	`FillMatchingMethod`	The method used to match offsetting order fills	

The `FillGroupingMethod` enumeration has the following members:

The `FillMatchingMethod` enumeration has the following members:

Default Behavior

The default `TradeBuilder` uses `FillGroupingMethod.FillToFill` and `FillMatchingMethod.FIFO` .

Check Open Positions

To check if you have a position open for a security as defined by the `FillGroupingMethod` , call the `HasOpenPosition` method.

```
has_open_position = self.TradeBuilder.HasOpenPosition(self.symbol)
```

Get Closed Trades

To get your closed trades, use the `ClosedTrades` property.

```py
trades = self.TradeBuilder.ClosedTrades
```

This property returns a list of `Trade` objects, which have the following attributes:

Trading and Orders

Trading Calendar

Introduction

The `TradingCalendar` contains a variety of events relevant to the assets in your algorithm. We source the event data from Quantlib .

Trading Day Properties

`TradingDay` objects represent the trading events of a single day. They have the following properties:

Get a Single Trading Day

To get the trading events of the current day, call the `GetTradingDay` method with no arguments.

```
PY
trading_day = self.TradingCalendar.GetTradingDay()
```

To get the trading events of a specific day, pass a `datetime` object to the `GetTradingDay` method.

```
PY
trading_day = self.TradingCalendar.GetTradingDay(datetime(2022, 6, 1))
```

Get Trading Days

To get all the trading events across a range of dates, pass start and end `datetime` objects to the `GetTradingDays` method.

```
PY
start_date = datetime(2022, 6, 1)
end_date = datetime(2022, 7, 1)
trading_days = self.TradingCalendar.GetTradingDays(start_date, end_date)
```

To get specific trading events across a range of dates, pass a `TradingDayType` enumeration member and the dates to the `GetDaysByType` method.

```
PY
trading_days = self.TradingCalendar.GetDaysByType(TradingDayType.OptionExpiration, start_date, end_date)
```

The `TradingDayType` enumeration has the following members:

Trading and Orders

Financial Advisors

Introduction

Financial Advisor accounts enable certified professionals to use a single trading algorithm to manage several client accounts. Our Interactive Brokers integration enables you to place FA group orders.

Group Routing

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```py
self.DefaultOrderProperties = InteractiveBrokersOrderProperties()
self.DefaultOrderProperties.FaGroup = "TestGroupEQ"
self.DefaultOrderProperties.FaMethod = "EqualQuantity"
self.DefaultOrderProperties.FaProfile = "TestProfileP"
self.DefaultOrderProperties.Account = "DU123456"
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `self.Portfolio["SPY"].Quantity` is zero.

Allocation Methods

The following table shows the supported allocation methods for FA group orders:

`FaMethod`	**Description**
`"EqualQuantity"`	Distributes shares equally between all accounts in the group. If you use this method, specify an order quantity.
`"NetLiq"`	Distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net liquidation value in each account and allocates shares based on these ratios. If you use this method, specify an order quantity.
`"AvailableEquity"`	Distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. If you use this method, specify an order quantity.
`"PctChange"`	Increases or decreases an already existing position. Positive percents increase positions and negative percents decrease positions. If you use this method, specify a percent instead of an order quantity.

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = InteractiveBrokersOrderProperties()
    self.DefaultOrderProperties.FaGroup = "TestGroupEQ"
    self.DefaultOrderProperties.FaMethod = "EqualQuantity"
    self.DefaultOrderProperties.FaProfile = "TestProfileP"
    self.DefaultOrderProperties.Account = "DU123456"

def OnData(self, slice: Slice) -> None:
    # Override the default order properties
    # "NetLiq" requires a order size input
    order_properties = InteractiveBrokersOrderProperties()
    order_properties.FaMethod = "NetLiq"
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    # "AvailableEquity" requires a order size input
    order_properties.FaMethod = "AvailableEquity"
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    # "PctChange" requires a percentage of portfolio input
    order_properties.FaMethod = "PctChange"
    self.SetHoldings(self.symbol, pct_portfolio, orderProperties=order_properties)
```

Subscription Requirements

To use FA group orders through our Interactive Brokers integration, you need to connect as a member of a Trading Firm and Institution organization. If you aren't currently on either of these tiers, upgrade your organization .

Reality Modeling

Reality Modeling

Key Concepts

Introduction

Reality models make backtests as realistic as possible to how the strategy would perform in live trading. These reality models model the behavior of things like the portfolio, brokerage, fills, slippage, options, and strategy capacity . Some reality models are set on a security basis and some are set at the portfolio level. The default models assume you trade highly liquid assets. If you trade high volumes or on illiquid assets, you should create custom reality models to be more realistic.

Security Level Models

LEAN's philosophy is to make the models per security as much as possible. The following models are security-level models:

- Fill
- Slippage
- Fee
- Brokerages
- Buying Power
- Settlement
- Option models
  - Pricing
  - Volatility
  - Exercise
  - Assignment
- Margin Interest Rate

To set a security-level reality model, call the set reality model method on the `Security` object. To get the correct method, see the preceding documentation page for each type of model.

```
# Set IBM to have a constant $1 transaction fee
self.Securities["IBM"].SetFeeModel(ConstantFeeModel(1))
```

PY

You can also set the security-specific models inside a security initializer .

```py
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetFeeModel(ConstantFeeModel(1))
```

Portfolio Level Models

A portfolio is a semi-closed system where the state updates over time as the value and quantity of assets in the portfolio fluctuate. It's a semi-closed system because the portfolio usually incurs transaction fees and you can add and deposit capital from the portfolio. LEAN models the portfolio holdings to track and update the average price of each asset with every transaction.

At the portfolio level, you can set the margin call model .

```py
self.Portfolio.SetMarginCallModel(DefaultMarginCallModel(self.Portfolio, self.DefaultOrderProperties))
```

Reality Modeling

Trade Fills

Trade Fills

Key Concepts

Introduction

A trade fill is the quantity and price at which your brokerage executes your order in the market. Fill models model how each type of order fills to accurately simulate the behavior of a real brokerage. Fill models determine the price and quantity of your fills, can incorporate spread costs, and work with the slippage model to add slippage into the fill price. If you trade US Equities, our built-in fill models can fill your orders at the official opening and closing auction prices .

Set Models

The brokerage model of your algorithm automatically sets the fill model for each security, but you can override it. To manually set the fill model of a security, call the `SetFillModel` method on the Security object.

PY

```
# In Initialize
security = self.AddEquity("SPY")
security.SetFillModel(ImmediateFillModel())
```

You can also set the fill model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `SetSecurityInitializer` before you create the subscriptions.

PY

```
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetFillModel(ImmediateFillModel())
```

To view all the pre-built fill models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the fill model of each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the EquityFillModel for Equities, the FutureFillModel for Futures, the FutureOptionFillModel for Future Options, and the ImmediateFillModel for all other asset classes.

Model Structure

Fill Models should extend the `FillModel` class. To implement your own fill model, override the methods in the `FillModel` class you wish to change. The class has a dedicated method for each order type. The method receives a `Security` and `Order` object and returns an `OrderEvent` object that contains information about the order status, fill quantity, and errors.

```
PY
class MyFillModel(FillModel):

    def MarketFill(self, asset: Security, order: MarketOrder) -> OrderEvent:
        return super().MarketFill(asset, order)

    def LimitFill(self, asse: Securityt, order: LimitOrder) -> OrderEvent:
        return super().LimitFill(asset, order)

    def LimitIfTouchedFill(self, asset: Security, order: LimitIfTouchOrder) -> OrderEvent:
        return super().LimitIfTouchedFill(asset, order)

    def StopMarketFill(self, asset: Security, order: StopMarketOrder) -> OrderEvent:
        return super().StopMarketFill(asset, order)

    def StopLimitFill(self, asset: Security, order: StopLimitOrder) -> OrderEvent:
        return super().StopLimitFill(asset, order)

    def MarketOnOpenFill(self, asset: Security, order: MarketOnOpenOrder) -> OrderEvent:
        return super().MarketOnOpenFill(asset, order)

    def MarketOnCloseFill(self, asset: Security, order: MarketOnCloseOrder) -> OrderEvent:
        return super().MarketOnCloseFill(asset, order)
```

Partial Fills

In live trading, your orders can partially fill. For example, if you have a buy limit order at the bid price for 100 shares and someone sells 10 shares with a market order, your order is partially filled. In backtests, the pre-built fill models assume orders completely fill. To simulate partial fills in backtests, create a custom fill model.

Stale Fills

Stale fills occur when you fill an order with price data that is timestamped an hour or more into the past. Stale fills usually only occur if you trade illiquid assets or if your algorithm uses daily data but you trade intraday with Scheduled Events. If your order is filled with stale data, the fill price may not be realistic. The pre-built fill models can only fill market orders with stale data. To adjust the length of time that needs to pass before an order is considered stale, set the `StalePriceTimeSpan` setting.

```
PY
self.Settings.StalePriceTimeSpan = timedelta(minutes=10)
```

Equity Model

Introduction

The `EquityFillModel` is the default fill model if you trade Equity assets with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
security.SetFillModel(EquityFillModel())
```

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following sections explain the fill logic of each order given these factors.

To view the implementation of this model, see the LEAN GitHub repository .

Market Orders

The model fills buy market orders at the best effort ask price plus slippage and fills sell market orders at the best effort bid price minus slippage.

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

The model only fills market orders during regular trading hours.

Limit Orders

To fill limit orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent back of trade

ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `EndTime` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

Once the model has a valid best effort `TradeBar` , it can fill the order. The following table shows the fill condition and fill price of limit orders. The model only fills the order once the fill condition is met.

Order Direction	Fill Condition	Fill Price
Buy	low price < limit price	min(open price, limit price)
Sell	high price > limit price	max(open price, limit price)

The model only fills limit orders when the exchange is open.

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

To fill limit if touched orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent back of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `EndTime` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

After the model has a valid best effort `TradeBar` , it can check if the trigger price has been touched. The following table describes the trigger condition of limit if touched orders for each order direction:

Order Direction	Trigger Condition
Buy	low price <= trigger price
Sell	high price >= trigger price

Once the limit if touched order triggers, the model starts to check if it should fill the order. The following table shows the fill condition and fill price of limit if touched orders. The model only fills the order once the fill condition is met

Order Direction	Fill Condition	Fill Price
Buy	Best effort ask price <= limit price	min(best effort ask price, limit price)
Sell	Best effort bid price >= limit price	max(best effort bid price, limit price)

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

The model only fills limit orders when the exchange is open.

The model won't trigger or fill limit if touched orders with stale data .

Stop Market Orders

To fill stop market orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent back of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `EndTime` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

Once the stop condition is met, the model fills the orders and sets the fill price.

Once the model has a valid best effort `TradeBar` , it can fill the order. The following table shows the stop condition and fill price of stop market orders. The model only fills the order once the stop condition is met.

Order Direction	Fill Condition	Fill Price
Buy	high price >= stop price	max(open price, stop price) + slippage
Sell	low price <= stop price	min(open price, stop price) - slippage

The model only fills stop market orders during regular trading hours.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The fill logic of stop limit orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of stop limit orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

The following table describes how the fill model processes the order given the data format and order direction. Once

the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

The model only fills stop limit orders when the exchange is open.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order direction:

Data Format	Order Direction	Fill Price
`Tick`	Buy	If the model receives the official opening auction price within one minute, the order fills at official open price + slippage. After one minute, the order fills at the most recent trade price + slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort ask price + slippage.
`Tick`	Sell	If the model receives the official opening auction price within one minute, the order fills at the official open price - slippage. After one minute, the order fills at the most recent trade price - slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort bid price - slippage.
`TradeBar`	Buy	Open price + slippage
`TradeBar`	Sell	Open price - slippage
`QuoteBar`	Buy	Best effort ask price + slippage
`QuoteBar`	Sell	Best effort bid price - slippage

The model checks the data format in the following order:

1. `Tick`
2. `TradeBar`
3. `QuoteBar`

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order direction:

Data Format	Order Direction	Fill Price
`Tick`	Buy	If the model receives the official closing auction price within one minute after the close, the order fills at official close price + slippage. After one minute, the order fills at the most recent trade price + slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort ask price + slippage.
`Tick`	Sell	If the model receives the official closing auction price within one minute after the close, the order fills at the official close price - slippage. After one minute, the order fills at the most recent trade price - slippage. If the security doesn't trade within the first two minutes after the close, the order fills at the best effort bid price - slippage.
`TradeBar`	Buy	Open price + slippage
`TradeBar`	Sell	Open price - slippage
`QuoteBar`	Buy	Best effort ask price + slippage
`QuoteBar`	Sell	Best effort bid price - slippage

The model checks the data format in the following order:

1. `Tick`
2. `TradeBar`
3. `QuoteBar`

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Combo Market Orders

The fill logic of combo market orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of combo market orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	Ask quote price + slippage
`Tick`	`Quote`	Sell	Bid quote price - slippage
`Tick`	`Trade`	Buy	Trade price + slippage
`Tick`	`Trade`	Sell	Trade price - slippage
`QuoteBar`		Buy	Ask close price + slippage
`QuoteBar`		Sell	Bid close price - slippage
`TradeBar`		Buy	Close price + slippage
`TradeBar`		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

The fill logic of combo limit orders depends on the data format of the security subscription and the order direction. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate

price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The fill logic of combo leg limit orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of combo leg limit orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Future Model

Introduction

The `FutureFillModel` is the default fill model if you trade Futures contracts with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
security.SetFillModel(FutureFillModel())
```

PY

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

To view the implementation of this model, see the LEAN GitHub repository .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	`TickType`	Combo Order Direction	Leg Order Direction	Price
`Tick`	`Quote`	Buy or sell	Buy	Ask price
`Tick`	`Quote`	Buy or sell	Sell	Bid price
`Tick`	`Trade`	Buy or sell	Buy or sell	Trade price
`QuoteBar`		Buy	Buy	Ask low price
`QuoteBar`		Buy	Sell	Bid low price
`QuoteBar`		Sell	Buy	Ask high price
`QuoteBar`		Sell	Sell	Bid high price
`TradeBar`		Buy	Buy or sell	Low price
`TradeBar`		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Future Option Model

Introduction

The `FutureOptionFillModel` is the default fill model if you trade Future Option contracts with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
security.SetFillModel(FutureOptionFillModel())
```

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

To view the implementation of this model, see the LEAN GitHub repository .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	`TickType`	Combo Order Direction	Leg Order Direction	Price
`Tick`	`Quote`	Buy or sell	Buy	Ask price
`Tick`	`Quote`	Buy or sell	Sell	Bid price
`Tick`	`Trade`	Buy or sell	Buy or sell	Trade price
`QuoteBar`		Buy	Buy	Ask low price
`QuoteBar`		Buy	Sell	Bid low price
`QuoteBar`		Sell	Buy	Ask high price
`QuoteBar`		Sell	Sell	Bid high price
`TradeBar`		Buy	Buy or sell	Low price
`TradeBar`		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Immediate Model

Introduction

The `ImmediateFillModel` is the default fill model if you trade non-Equity assets with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
security.SetFillModel(ImmediateFillModel())
```
PY

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

To view the implementation of this model, see the LEAN GitHub repository .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	`TickType`	Combo Order Direction	Leg Order Direction	Price
`Tick`	`Quote`	Buy or sell	Buy	Ask price
`Tick`	`Quote`	Buy or sell	Sell	Bid price
`Tick`	`Trade`	Buy or sell	Buy or sell	Trade price
`QuoteBar`		Buy	Buy	Ask low price
`QuoteBar`		Buy	Sell	Bid low price
`QuoteBar`		Sell	Buy	Ask high price
`QuoteBar`		Sell	Sell	Bid high price
`TradeBar`		Buy	Buy or sell	Low price
`TradeBar`		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Latest Price Model

Introduction

The `LatestPriceFillModel` fills trades completely and immediately.

```
security.SetFillModel(LatestPriceFillModel())
```

PY

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If there is no `QuoteBar` available, it uses the OHLC prices from the `Security` object. If there is a `QuoteBar` available, the fill model gets the most recent `TradeBar` . If the `TradeBar` is more recent, it uses the `TradeBar` data. Otherwise, it uses the `QuoteBar` data.

To view the implementation of this model, see the LEAN GitHub repository .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	`TickType`	Combo Order Direction	Leg Order Direction	Price
`Tick`	`Quote`	Buy or sell	Buy	Ask price
`Tick`	`Quote`	Buy or sell	Sell	Bid price
`Tick`	`Trade`	Buy or sell	Buy or sell	Trade price
`QuoteBar`		Buy	Buy	Ask low price
`QuoteBar`		Buy	Sell	Bid low price
`QuoteBar`		Sell	Buy	Ask high price
`QuoteBar`		Sell	Sell	Bid high price
`TradeBar`		Buy	Buy or sell	Low price
`TradeBar`		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Reality Modeling

Slippage

Slippage

Key Concepts

Introduction

Slippage is the difference between the fill price you expect to get for an order and the actual fill price. Since the price can move in the direction of your trade or against the direction of your trade while you wait for the order to fill, slippage can be positive or negative. Slippage models model slippage to make backtest results more realistic.

Factors Impacting Slippage

There are many factors that can impact slippage, including the trading engine, brokerage connection, and market dynamics.

Trading Engine

How long does it take from when you place an order to when it's sent to the brokerage? Longer delays lead to more slippage.

Brokerage Connection

How long does it take for your brokerage to receive an order that you send? Slow internet connections, long travel distances, and poor infrastructure lead to more slippage

Market Dynamics

How volatile is the current market environment? More volatility leads to more slippage.

Does the market consist of sophisticated microsecond arbitrageurs? If your order creates an arbitrage opportunity, it can cause more slippage.

Set Models

The brokerage model of your algorithm automatically sets the slippage model for each security, but you can override it. To manually set the slippage model of a security, call the `SetSlippageModel` method on the `Security` object.

```py
# In Initialize
security = self.AddEquity("SPY")
security.SetSlippageModel(VolumeShareSlippageModel())
```

You can also set the slippage model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `SetSecurityInitializer` before you create the subscriptions.

```
PY
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetSlippageModel(VolumeShareSlippageModel())
```

To view all the pre-built slippage models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the slippage model of each security. The default brokerage model is the `DefaultBrokerageModel` , which uses the ConstantSlippageModel to model zero slippage for all securities.

Model Structure

Slippage models should implement the `ISlippageModel` interface. Extensions of the `ISlippageModel` interface must implement the `GetSlippageApproximation` method, which calculates the slippage quantity.

```
PY
class MySlippageModel:

    def GetSlippageApproximation(self, asset: Security, order: Order) -> float:
        return asset.Price * 0.0001 * np.log10(2*float(order.AbsoluteQuantity))
```

Examples

Demonstration Algorithms
CustomModelsAlgorithm.py Python

Slippage

Supported Models

Introduction

This page describes the pre-built slippage models in LEAN. If none of these models perform exactly how you want, create a custom slippage model .

Constant Model

The `ConstantSlippageModel` applies a constant percentage of slippage to each order. It's the default slippage model of the DefaultBrokerageModel .

```
security.SetSlippageModel(ConstantSlippageModel(0))
```
PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`slippagePercent`	`float`	The slippage percent for each order. The value must be in the interval (0, 1).	

To view the implementation of this model, see the LEAN GitHub repository .

Volume Share Model

The `VolumeShareSlippageModel` calculates the slippage of each order by multiplying the price impact constant by the square of the ratio of the order to the total volume. If the volume of the current bar is zero, the slippage percent is

$$volumeLimit^2 * priceImpact$$

where **volumeLimit** and **priceImpact** are custom input variables. If the volume of the current bar is positive, the slippage percent is

$$\min(\frac{|orderQuantity|}{barVolume}, volumeLimit)^2 * priceImpact$$

where **orderQuantity** is the quantity of the order and **barVolume** is the volume of the current bar. If the security subscription provides `TradeBar` data, the **barVolume** is the volume of the current bar. If the security subscription provides `QuoteBar` data, the **barVolume** is the bid or ask size of the current bar. CFD, Forex, and Crypto data often doesn't include volume. If there is no volume reported for these asset classes, the model returns zero slippage.

```
security.SetSlippageModel(VolumeShareSlippageModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`volumeLimit`	`float`	Maximum percent of historical volume that can fill in each bar. 0.5 means 50% of historical volume. 1.0 means 100%.	0.025
`priceImpact`	`float`	Scaling coefficient for price impact. Larger values will result in more simulated price impact. Smaller values will result in less simulated price impact.	0.1

To view the implementation of this model, see the LEAN GitHub repository .

Reality Modeling

Transaction Fees

Transaction Fees

Key Concepts

Introduction

Your orders incur a transaction fee when a brokerage fills them in the market. LEAN uses transaction fee models in backtesting to model the live trading fees you would incur with the strategy. Transaction fee models make backtest results more realistic. To give your backtests the most accurate fees, LEAN contains transaction fee models that model the fee structure of many popular brokerages.

Set Models

The brokerage model of your algorithm automatically sets the fee model for each security, but you can override it. To manually set the fee model of a security, call the `SetFeeModel` method on the `Security` object.

PY

```
# In Initialize
security = self.AddEquity("SPY")
security.SetFeeModel(ConstantFeeModel(0))
```

You can also set the fee model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `SetSecurityInitializer` before you create the subscriptions.

PY

```
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetFeeModel(ConstantFeeModel(0))
```

In live trading, the `SetFeeModel` method isn't ignored. If we use order helper methods like `SetHoldings` , the fee model helps to calculate the order quantity. However, the algorithm doesn't update the cash book with the fee from the fee model. The algorithm uses the actual fee from the brokerage to update the cash book.

To view all the pre-built fee models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the fill model for each security. The default brokerage model is the `DefaultBrokerageModel` , which set the ConstantFeeModel with no fees for Forex, CFD, and Crypto assets and sets the InteractiveBrokersFeeModel for the remaining asset classes.

Model Structure

Fee models should extend the `FeeModel` class. Extensions of the `FeeModel` class must implement the `GetOrderFee` method, which receives `OrderFeeParameters` and returns an `OrderFee` that represents a cash amount in a currency.

```
PY
class MyFeeModel(FeeModel):

    def GetOrderFee(self, parameters: OrderFeeParameters) -> OrderFee:
        return OrderFee(CashAmount(0.5, 'USD'))
```

The `OrderFeeParameters` object has the following members:

Negative Transaction Fees

If you short a security and receive interest payments, they are negative transaction fees.

Examples

Demonstration Algorithms
CustomModelsAlgorithm.py Python RawPricesCoarseUniverseAlgorithm.py Python

Transaction Fees

Supported Models

Introduction

This page describes some of the pre-built fee models in LEAN. For more brokerage-specific fee models, see the brokerage model documentation . If none of these models perform exactly how you want, create a custom fee model .

Constant Model

The `ConstantFeeModel` applies the absolute value of a constant fee to each order. It's the default fee model of the DefaultBrokerageModel if you trade Forex, CFD, or Crypto assets.

```
security.SetFeeModel(ConstantFeeModel(0.05))
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fee`	`float`	The order fee quantity	
`currency`	`str`	The order fee currency	"USD"

To view the implementation of this model, see the LEAN GitHub repository .

Interactive Brokers Model

The `InteractiveBrokersFeeModel` models the fees of Interactive Brokers .

```
security.SetFeeModel(InteractiveBrokersFeeModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`monthlyForexTradeAmountInUSDollars`	`float`	Monthly Forex dollar volume traded	0
`monthlyOptionsTradeAmountInContracts`	`float`	Monthly Option contracts traded	0

The following table describes which currency the `InteractiveBrokersFeeModel` charges fees in for each asset class:

Asset Class	Fee Currency
US Equity	USD
India Equity	INR
Equity Options	USD
Forex	USD
US Futures	USD
Hong Kong Futures	The contract quote currency (CNH, HKD, or USD)
US Future Options	USD
Hong Kong Future Options	The contract quote currency (CNH, HKD, or USD)
Index Options	USD

The following sections describe the trading fees of each asset class. To view the implementation of this model, see the LEAN GitHub repository .

US Equities

US Equity trades cost 0.005/share with a 1 minimum fee and a 0.5% maximum fee.

Equity Options and Index Options

Equity Options and Index Options fees are a function of your monthly volume and the premium of the contract you trade. The following table shows the fees for each volume tier:

Monthly Volume (Contacts)	Premium ($)	Fee per Contract ($)
<= 10,000	< 0.05	0.25
<= 10,000	0.05 <= premium < 0.10	0.50
<= 10,000	>= 0.10	0.70
10,000 < volume <= 50,000	< 0.05	0.25
10,000 < volume <= 50,000	>= 0.05	0.50
50,000 < volume <= 100,000	Any	0.25
> 100,000	Any	0.15

By default, LEAN models your fees at the tier with the lowest monthly volume. To adjust the fee tier, manually set the fee model and provide a `monthlyOptionsTradeAmountInContracts` argument.

There is no fee to exercise Option contracts.

Forex

Forex fees are a function of your monthly Forex trading volume. The following table shows the fee tiers:

Monthly Volume (USD)	Commission Rate (%)	Minimum Fee ($)
<= 1B	0.002	2
1B < volume <= 2B	0.0015	1.5
2B < volume <= 5B	0.001	1.25
> 5B	0.0008	1

By default, LEAN models your fees at the tier with the lowest monthly volume. To adjust the fee tier, manually set the fee model and provide a `monthlyForexTradeAmountInUSDollars` argument.

US Futures

US Futures fees depend on the contracts you trade. The following table shows the base fee per contract for each Future:

Contract Symbol	Market	Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
E-mini Futures				
ES	CME	E-mini S&P 500 Futures	0.85	1.28
NQ	CME	E-mini Nasdaq-100 Futures	0.85	1.28
YM	CBOT	E-mini Dow ($5) Futures	0.85	1.28
RTY	CME	E-mini Russell 2000 Index Futures	0.85	1.28
EMD	CME	E-mini S&P MidCap 400 Futures	0.85	1.28
Micro E-mini Futures				
MYM	CBOT	Micro E-mini Dow Jones Industrial Average Index Futures	0.25	0.3
M2K	CME	Micro E-mini Russell 2000 Index Futures	0.25	0.3

Contract Symbol	Market	Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
MES	CME	Micro E-mini Standard and Poor's 500 Stock Price Index Futures	0.25	0.3
MNQ	CME	Micro E-mini Nasdaq-100 Index Futures	0.25	0.3
2YY	CBOT	Micro 2-Year Yield Futures	0.25	0.3
5YY	CBOT	Micro 5-Year Yield Futures	0.25	0.3
10Y	CBOT	Micro 10-Year Yield Futures	0.25	0.3
30Y	CBOT	Micro 30-Year Yield Futures	0.25	0.3
MCL	NYMEX	Micro WTI Crude Oil Futures	0.25	0.3
MGC	COMEX	Micro Gold Futures	0.25	0.3
SIL	COMEX	Micro Silver Futures	0.25	0.3
Cryptocurrency Futures				
BTC	CME	Bitcoin Futures	5	6
MIB	CME	BTIC on Micro Bitcoin Futures	2.25	2.5
MBT	CME	Micro Bitcoin Futures	2.25	2.5
MET	CME	Micro Ether Futures	0.2	0.2
MRB	CME	BTIC on Micro Ether Futures	0.2	0.2
E-mini FX Futures				
E7	CME	E-mini Euro FX Futures	0.5	0.85
J7	CME	E-mini Japanese Yen Futures	0.5	0.85
Micro E-mini FX Futures				

Contract Symbol	Market	Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
M6E	CME	Micro Euro/U.S. Dollar (EUR/USD) Futures	0.15	0.24
M6A	CME	Micro Australian Dollar/U.S. Dollar (AUD/USD) Futures	0.15	0.24
M6B	CME	Micro British Pound Sterling/U.S. Dollar (GBP/USD) Futures	0.15	0.24
MCD	CME	Micro Canadian Dollar/U.S.Dollar(CAD/USD) Futures	0.15	0.24
MJY	CME	Micro Japanese Yen/U.S. Dollar (JPY/USD) Futures	0.15	0.24
MSF	CME	Micro Swiss Franc/U.S. Dollar (CHF/USD) Futures	0.15	0.24
M6J	CME	Micro USD/JPY Futures	0.15	0.24
MIR	CME	Micro INR/USD Futures	0.15	0.24
M6C	CME	Micro USD/CAD Futures	0.15	0.24
M6S	CME	Micro USD/CHF Futures	0.15	0.24
MNH	CME	Micro USD/CNH Futures	0.15	0.24

If you trade a contract that's not in the preceding table, the base fee is 0.85/contract and the exchange fee is 1.60/contract.

In addition to the base fee and exchange fee, there is a $0.02/contract regulatory fee.

Futures Options

Futures Options fees depend on the contracts you trade. The following table shows the base fee per contract for each Future:

Contract Symbol	Market	Underlying Futures Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
E-mini Futures Options				

Contract Symbol	Market	Underlying Futures Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
ES	CME	E-mini S&P 500 Futures	0.85	0.55
NQ	CME	E-mini Nasdaq-100 Futures	0.85	0.55
YM	CBOT	E-mini Dow ($5) Futures	0.85	0.55
RTY	CME	E-mini Russell 2000 Index Futures	0.85	0.55
EMD	CME	E-mini S&P MidCap 400 Futures	0.85	0.55
Micro E-mini Futures Options				
MYM	CBOT	Micro E-mini Dow Jones Industrial Average Index Futures	0.25	0.2
M2K	CME	Micro E-mini Russell 2000 Index Futures	0.25	0.2
MES	CME	Micro E-mini Standard and Poor's 500 Stock Price Index Futures	0.25	0.2
MNQ	CME	Micro E-mini Nasdaq-100 Index Futures	0.25	0.2
2YY	CBOT	Micro 2-Year Yield Futures	0.25	0.2
5YY	CBOT	Micro 5-Year Yield Futures	0.25	0.2
10Y	CBOT	Micro 10-Year Yield Futures	0.25	0.2
30Y	CBOT	Micro 30-Year Yield Futures	0.25	0.2
MCL	NYMEX	Micro WTI Crude Oil Futures	0.25	0.2
MGC	COMEX	Micro Gold Futures	0.25	0.2
SIL	COMEX	Micro Silver Futures	0.25	0.2

Contract Symbol	Market	Underlying Futures Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
Cryptocurrency Futures Options				
BTC	CME	Bitcoin Futures	5	5
MIB	CME	BTIC on Micro Bitcoin Futures	1.25	2.5
MBT	CME	Micro Bitcoin Futures	1.25	2.5
MET	CME	Micro Ether Futures	0.1	0.2
MRB	CME	BTIC on Micro Ether Futures	0.1	0.2

If you trade a contract that's not in the preceding table, the base fee is 0.85/contract and the exchange fee is 1.60/contract.

In addition to the base fee and exchange fee, there is a $0.02/contract regulatory fee.

Binance Model

The `BinanceFeeModel` models the fees of spot trades on Binance and Binance US .

```
security.SetFeeModel(BinanceFeeModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`mFee`	`float`	Maker fee value	0.001
`tFee`	`float`	Taker fee value	0.001

The `BinanceFeeModel` charges the order fees of Binance and Binance US at the VIP 0 level, which is a 0.1% maker and taker fee. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

To view the implementation of this model, see the LEAN GitHub repository .

Binance Futures Model

The `BinanceFuturesFeeModel` models the Binance Futures live trading fees .

```
security.SetFeeModel(BinanceFuturesFeeModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`mUsdtFee`	`float`	Maker fee value for USDT pair contracts	0.0002
`tUsdtFee`	`float`	Taker fee value for USDT pair contracts	0.0004
`mBusdFee`	`float`	Maker fee value for BUSD pair contracts	0.00012
`tUsdtFee`	`float`	Taker fee value for BUSD pair contracts	0.00036

By default, the `BinanceFuturesFeeModel` charges the order fees of Binance Futures at the Regular User level. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceFuturesFeeModel` charges fees in the currency you receive from a trade. For example, if you buy BTCUSD, you pay fees in BTC. If you sell BTCUSD, you pay fees in USD.

To view the implementation of this model, see the LEAN GitHub repository .

Binance Coin Futures Model

The `BinanceCoinFuturesFeeModel` models the Binance Coin Futures live trading fees .

```
security.SetFeeModel(BinanceCoinFuturesFeeModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`mFee`	`float`	Maker fee value	0.0001
`tFee`	`float`	Taker fee value	0.0005

By default, the `BinanceCoinFuturesFeeModel` charges the order fees of Binance Coin Futures at the Regular User level. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceCoinFuturesFeeModel` charges fees in the currency you receive from a trade. For example, if you buy BTCUSDT, you pay fees in BTC. If you sell BTCUSDT, you pay fees in USDT.

To view the implementation of this model, see the LEAN GitHub repository .

Bitfinex Model

The `BitfinexFeeModel` models the Bitfinex live trading fees .

```
security.SetFeeModel(BitfinexFeeModel())
```

The `BitfinexFeeModel` charges a 0.1% maker fee and a 0.2% taker fee. If you place a limit order that hits a hidden order or you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you place a hidden order or you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Bitfinex adjusts your fees based on your 30-day trading volume and LEO balance, but we don't currently model these metrics to adjust fees.

The `BitfinexFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

To view the implementation of this model, see the LEAN GitHub repository .

GDAX Model

The `GDAXFeeModel` models the Coinbase live trading fees .

```
security.SetFeeModel(GDAXFeeModel())
```

The `GDAXFeeModel` models the order fees of Coinbase at the $50K-100K pricing tier for all Crypto pairs, so it charges a 0.5% maker and taker fee for most pairs. The following table shows the Coinbase Stable Pairs, which charge a 0% maker fee and a 0.1% taker fee:

Stable Pairs			
DAIUSDC	DAIUSD	GYENUSD	PAXUSD
PAXUSDT	MUSDUSD	USDCEUR	USDCGBP
USDTEUR	USDTGBP	USDTUSD	USDTUSDC
USTEUR	USTUSD	USTUSDT	WBTCBTC

If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Coinbase adjusts your fees based on your 30-day trading volume, but we don't currently model trading volume to adjust fees.

The `GDAXFeeModel` models the adjustments Coinbase has made to their fees over time. The following table shows the fees for each time period:

Time Period (UTC)	Maker Fee (%)	Taker Fee (%)
Time < 3/23/2019 1:30AM	0	0.3
3/23/2019 1:30AM <= Time < 10/8/2019 12:30AM	0.15	0.25
10/8/2019 12:30AM <= Time	0.5	0.5

The `GDAXFeeModel` charges fees in the quote currency .

To view the implementation of this model, see the LEAN GitHub repository .

Kraken Model

The `KrakenFeeModel` models the fees of Kraken .

```
security.SetFeeModel(KrakenFeeModel())
```

The `KrakenFeeModel` model the order fees of Kraken. For trading pairs that contain only Crypto assets, this fee model models the lowest tier in Kraken's tiered fee structure, which is a 0.16% maker fee and a 0.26% taker fee. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. For trading pairs that have any of the following currencies as the base currency in the pair, the fee is 0.2%:

- CAD
- EUR
- GBP
- JPY
- USD
- USDT
- DAI
- USDC

The `KrakenFeeModel` charges fees in the quote currency for buy orders and in the base currency for sell orders. To override these settings, define the `KrakenOrderProperties` .

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = KrakenOrderProperties()
    self.DefaultOrderProperties.FeeInBase = True
    self.DefaultOrderProperties.FeeInQuote = False

def OnData(self, slice: Slice) -> None:
    # Override the default order properties
    order_properties = KrakenOrderProperties()
    order_properties.FeeInQuote = True
    order_properties.FeeInBase = False
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Kraken adjusts your fees based on your 30-day trading volume, but the `KrakenFeeModel` don't currently model trading volume to adjust fees.

To view the implementation of this model, see the LEAN GitHub repository .

Samco Model

The `SamcoFeeModel` models the fees of Samco .

```
security.SetFeeModel(SamcoFeeModel())
```

The `SamcoFeeModel` models the order fees of Samco by its Equity Intraday fee structure. The following table shows the fees:

Charge Item	Fee
Brokerage Fee	₹20 per trade or 0.02% (whichever is lower)
Exchange Transaction Charge	0.00345%
Securities Transaction Tax	0.025%
Goods and Services Tax	18%
SEBI Charges	0.0001%
Stamp Duty	0.003%

The `SamcoFeeModel` charges fees in INR.

To view the implementation of this model, see the LEAN GitHub repository .

TD Ameritrade Model

The `TDAmeritradeFeeModel` models the fees of TD Ameritrade .

```
security.SetFeeModel(TDAmeritradeFeeModel())
```

The `TDAmeritradeFeeModel` charges $0 USD for Equity trades.

To view the implementation of this model, see the LEAN GitHub repository .

Wolverine Model

The `WolverineFeeModel` models the fees of Wolverine Execution Services.

```
security.SetFeeModel(WolverineFeeModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`feesPerShare`	`float` / `NoneType`	The fees per share to apply. If `None` , it uses 0.005.	`None`

The `WolverineFeeModel` charges fees in USD.

To view the implementation of this model, see the LEAN GitHub repository .

Zerodha Model

The `ZerodhaFeeModel` models the fees of Zerodha .

```
security.SetFeeModel(ZerodhaFeeModel())
```

PY

The `ZerodhaFeeModel` models the order fees of Zerodha with its Equity Intraday fee structure. The following table shows the fees:

Charge Item	Fee
Brokerage Fee	₹20 per trade or 0.03% (whichever is lower)
Exchange Transaction Charge	0.00345%
Securities Transaction Tax	0.025%
Goods and Services Tax	18%
SEBI Charges	0.0001%
Stamp Duty	0.003%

The `ZerodhaFeeModel` charges fees in INR.

To view the implementation of this model, see the LEAN GitHub repository .

Reality Modeling

Brokerages

Brokerages

Key Concepts

Introduction

Brokerages provide you with a connection to the market so you can fill trades. Brokerage models simulate the live behavior of a real brokerage. To avoid sending invalid orders for execution in live trading, the brokerage model validates your orders before LEAN sends them to the real brokerage. Brokerage models combine together all of the models relevant for a brokerage. If you set the appropriate brokerage model, the supported order types, default markets, and some of the security-level models are appropriately set in your algorithm.

Set Models

To set a brokerage model, in the `Initialize` method, call the `SetBrokerageModel` method with a `BrokerageName` and an `AccountType` . If you set a brokerage model, it overrides any security level models you manually set in your algorithm.

```
PY
self.SetBrokerageModel(BrokerageName.OandaBrokerage) # Defaults to margin account
self.SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin) # Overrides the default account type
```

In live trading, LEAN doesn't ignore your `SetBrokerageModel` method calls. LEAN uses some of the brokerage model rules to catch invalid orders before they reach your real brokerage.

To view all the pre-built brokerage models, see Supported Models .

Default Behavior

The default brokerage model is the `DefaultBrokerageModel` , but LEAN has many other brokerage models you can use in your algorithms. For more information about the `DefaultBrokerageModel` , see QuantConnect Paper Trading .

Modeled Properties

Brokerage models model that following properties:

- Transaction fees
- Supported asset classes
- Account types
- Support for extended market hours

- Leverage for assets
- Trade settlement rules
- Order properties and updates

Model Structure

Brokerage models should extend the `DefaultBrokerageModel` class. Extensions of the `DefaultBrokerageModel` class should implement the following methods:

```
class MyBrokerageModel(DefaultBrokerageModel):
    DefaultMarkets = {}
    RequiredFreeBuyingPowerPercent = 0

    def __init__(self, accountType: AccountType = AccountType.Margin):
        self.AccountType = accountType
        self.ShortableProvider = NullShortableProvider()

    def CanSubmitOrder(self, security: Security, order: Order,
         message: BrokerageMessageEvent) -> bool:
        return super().CanSubmitOrder(security, order, message)

    def CanUpdateOrder(self, security: Security, order: Order,

    def GetMarginInterestRateModel(self, security: Security) -> IMarginInterestRateModel:
        return super().GetMarginInterestRateModel(security)

    def GetShortableProvider(self) -> IShortableProvider:
        return self.ShortableProvider
```

Custom brokerage models give you enormous control over your algorithm behavior and allow you to model virtually any brokerage in the world.

Examples

Demonstration Algorithms
BrokerageModelAlgorithm.py Python

Brokerages

Supported Models

Brokerage models combine together all of the models relevant for a brokerage. The following brokerage models are available:

QuantConnect Paper Trading

Binance

Bitfinex

Coinbase

Interactive Brokers

Kraken

Oanda

Samco

TD Ameritrade

Tradier

Trading Technologies

Wolverine

Zerodha

Reality Modeling
Live Trading Brokerages

Supported Models

QuantConnect Paper Trading

Introduction

This page explains the `DefaultBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage) # Defaults to margin account
self.SetBrokerageModel(BrokerageName.QuantConnectBrokerage, AccountType.Margin) # Overrides the default
account type
```

PY

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `DefaultBrokerageModel` supports trading for all asset classes .

Orders

The following sections describe how the `DefaultBrokerageModel` handles orders.

Order Types

The following table describes the available order types for each asset class that the `DefaultBrokerageModel` supports:

Order Type	US Equity	Equity Options	Crypto	Crypto Futures	Forex	CFD	Futures	Futures Options	Index Options
MarketOrder	✓	✓	✓	✓	✓	✓	✓	✓	✓
LimitOrder	✓	✓	✓	✓	✓	✓	✓	✓	✓
LimitIfTouchedOrder	✓	✓	✓	✓	✓	✓	✓	✓	✓
StopMarketOrder	✓	✓	✓	✓	✓	✓	✓	✓	✓
StopLimitOrder	✓	✓	✓	✓	✓	✓	✓	✓	✓
MarketOnOpenOrder	✓	✓	✓		✓	✓			✓
MarketOnCloseOrder	✓	✓	✓		✓	✓	✓	✓	✓
ComboMarketOrder		✓						✓	✓
ComboLimitOrder		✓						✓	✓
ComboLegLimitOrder		✓						✓	✓
ExerciseOption		✓ Not supported for cash-settled Options						✓	

Time In Force

The `DefaultBrokerageModel` supports the following TimeInForce instructions:

- `Day`
- `GoodTilCanceled`
- `GoodTilDate`

Updates

The `DefaultBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the `DefaultBrokerageModel` uses for each `SecurityType` :

`SecurityType`	**Fill Model**
`Equity`	EquityFillModel
`Future`	FutureFillModel
`FutureOption`	FutureOptionFillModel
Remaining `SecurityType` values	ImmediateFillModel

Slippage

The `DefaultBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
PY

security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `DefaultBrokerageModel` uses the ConstantFeeModel with no fees for Forex, CFD, Crypto, and Crypto Future assets and the InteractiveBrokersFeeModel for the remaining asset classes.

```
PY

# For Forex, CFD, Crypto, and Crypto Future assets:
security.SetFeeModel(ConstantFeeModel(0))

# For the remaining asset classes:
security.SetFeeModel(InteractiveBrokersFeeModel())
```

Buying Power

The `DefaultBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`
Future Options	`FuturesOptionsMarginModel`
Index Options	`OptionMarginModel`
Crypto	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
CryptoFuture	`CryptoFutureMarginModel`
Forex	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
Other	`SecurityMarginModel`

If you have a margin account, the `DefaultBrokerageModel` allows 2x leverage for Equities, 50x leverage for Forex and CFDs, and 1x leverage for the remaining asset classes.

Settlement

The following table shows which settlement model the `DefaultBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `DefaultBrokerageModel` uses the ImmediateSettlementModel .

```py
# For US Equities with a cash account:
security.SettlementModel = DelayedSettlementModel(Equity.DefaultSettlementDays,
Equity.DefaultSettlementTime)

# For Equity Options with a cash account:
security.SettlementModel = DelayedSettlementModel(Option.DefaultSettlementDays,
Option.DefaultSettlementTime)

# For Futures
security.SettlementModel = FutureSettlementModel()

# For remaining cases:
security.SettlementModel = ImmediateSettlementModel()
```

Margin Interest Rate

The `DefaultBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `DefaultBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA
Forex	Oanda
Cfd	Oanda
Crypto	GDAX
CryptoFuture	Binance

Supported Models

Binance

Introduction

This page explains the Binance brokerage models, including the asset classes they supports, their default security-level models , and their default markets.

```
# Binance Spot
self.SetBrokerageModel(BrokerageName.Binance, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.Binance, AccountType.Margin)

# Binance Futures
self.SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin)
self.SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin)

# Binance US Spot
self.SetBrokerageModel(BrokerageName.BinanceUS, AccountType.Cash)
```

To view the implementation of these models, see the following pages in the LEAN GitHub repository:

- BinanceBrokerageModel.cs
- BinanceFuturesBrokerageModel.cs
- BinanceCoinFuturesBrokerageModel.cs
- BinanceUSBrokerageModel.cs

Asset Classes

The Binance brokerage models support trading Crypto and Crypto Futures .

The Binance US brokerage model supports trading Crypto .

Orders

The Binance and Binance US brokerage models support several order types and order properties, but don't support order updates.

Order Types

The following table describes the available order types for each asset class that the Binance and Binance US brokerage models support:

Order Type	Crypto	Crypto Futures
MarketOrder	✓	✓
LimitOrder	✓	✓
StopLimitOrder	✓	

Order Properties

The Binance and Binance US brokerage models supports custom order properties. The following table describes the members of the `BinanceOrderProperties` object that you can set to customize order execution:

Property	Description
`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`
`PostOnly`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.

PY

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = BinanceOrderProperties()
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled
    self.DefaultOrderProperties.PostOnly = False

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = BinanceOrderProperties()
    order_properties.TimeInForce = TimeInForce.Day
    order_properties.PostOnly = True
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    order_properties.TimeInForce = TimeInForce.GoodTilDate(datetime(year, month, day))
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The Binance and Binance US brokerage models don't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The Binance brokerage models use the ImmediateFillModel .

Slippage

The Binance brokerage models use the ConstantSlippageModel with zero slippage.

PY

```
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The following table shows the fee model that each Binance brokerage model uses:

Brokerage Model	Fee Model
`BinanceBrokerageModel`	BinanceFeeModel
`BinanceFuturesBrokerageModel`	BinanceFuturesFeeModel
`BinanceCoinFuturesBrokerageModel`	BinanceCoinFuturesFeeModel
`BinanceUSBrokerageModel`	BinanceFeeModel

The Binance brokerage models use the default argument values for each fee model so that it models the current Binance fee schedule.

Buying Power

The Binance brokerage models use the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

The following table shows the maximum leverage each brokerage model allows for margin accounts:

Brokerage Model	Maximum Leverage
`BinanceBrokerageModel`	3
`BinanceFuturesBrokerageModel`	25
`BinanceCoinFuturesBrokerageModel`	25

The `BinanceUSBrokerageModel` doesn't currently support margin trading.

Settlement

The Binance brokerage models use the ImmediateSettlementModel .

Margin Interest Rate

The following table shows the margin interest rate model that the Binance brokerages use:

Brokerage Model	Margin Interest Rate Model
`BinanceBrokerageModel`	NullMarginInterestRateModel
`BinanceFuturesBrokerageModel`	BinanceFutureMarginInterestRateModel for Crypto Perpetual Futures and NullMarginInterestRateModel for other assets
`BinanceCoinFuturesBrokerageModel`	BinanceFutureMarginInterestRateModel for Crypto Perpetual Futures and NullMarginInterestRateModel for other assets
`BinanceUSBrokerageModel`	NullMarginInterestRateModel

Default Markets

The following table shows the default market of the Binance brokerage models:

Brokerage Model	Market
`BinanceBrokerageModel`	`Market.Binance`
`BinanceFuturesBrokerageModel`	`Market.Binance`
`BinanceCoinFuturesBrokerageModel`	`Market.Binance`
`BinanceUSBrokerageModel`	`Market.BinanceUS`

Supported Models

Bitfinex

Introduction

This page explains `BitfinexBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `BitfinexBrokerageModel` supports trading Crypto .

Orders

The `BitfinexBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `BitfinexBrokerageModel` supports:

Order Type	Crypto
MarketOrder	✓
LimitOrder	✓
LimitIfTouchedOrder	✓
StopMarketOrder	✓
StopLimitOrder	✓
MarketOnOpenOrder	✓
MarketOnCloseOrder	✓

Order Properties

The `BitfinexBrokerageModel` supports custom order properties. The following table describes the members of the `BitfinexOrderProperties` object that you can set to customize order execution:

Property	Description
`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`
`Hidden`	A flag to signal that the order should be hidden. Hidden orders do not appear in the order book, so they do not influence other market participants. Hidden orders incur the taker fee.
`PostOnly`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.

PY

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = BitfinexOrderProperties()
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled
    self.DefaultOrderProperties.Hidden = False
    self.DefaultOrderProperties.PostOnly = False

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = BitfinexOrderProperties()
    order_properties.TimeInForce = TimeInForce.Day
    order_properties.Hidden = True
    order_properties.PostOnly = False
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    order_properties.TimeInForce = TimeInForce.GoodTilDate(datetime(year, month, day))
    order_properties.Hidden = False
    order_properties.PostOnly = True
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The `BitfinexBrokerageModel` supports order updates .

Fills

The `BitfinexBrokerageModel` uses the ImmediateFillModel .

Slippage

The `BitfinexBrokerageModel` uses the ConstantSlippageModel with zero slippage.

PY

```
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `BitfinexBrokerageModel` uses the BitfinexFeeModel with the default argument values that models the current

Bitfinex fee schedule.

Buying Power

The `BitfinexBrokerageModel` uses the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

If you have a margin account, the `BitfinexBrokerageModel` allows 3.3x leverage.

Settlement

The `BitfinexBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `BitfinexBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `BitfinexBrokerageModel` is `Market.Bitfinex` .

Supported Models

Coinbase

Introduction

This page explains `GDAXBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.GDAX, AccountType.Cash)
```

PY

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `GDAXBrokerageModel` supports trading Crypto .

Orders

The `GDAXBrokerageModel` supports several order types and order properties, but it doesn't support order updates.

Order Types

The following table describes the available order types for each asset class that the `GDAXBrokerageModel` supports:

Order Type	Crypto
MarketOrder	✓
LimitOrder	✓
StopMarketOrder	✓ Supported after 2019-03-23 in backtests. For reference, see the Coinbase Market Structure Update on the Coinbase website.
StopLimitOrder	✓

Order Properties

The `GDAXBrokerageModel` supports custom order properties. The following table describes the members of the `GDAXOrderProperties` object that you can set to customize order execution:

Property	Description
`TimeInForce`	A TimeInForce instruction to apply to the order. The `GoodTilCanceled` `TimeInForce` is supported.
`PostOnly`	A flag that signals the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.

```
PY
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = GDAXOrderProperties()
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled
    self.DefaultOrderProperties.PostOnly = False

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = GDAXOrderProperties()
    order_properties.TimeInForce = TimeInForce.GoodTilCanceled
    order_properties.PostOnly = True
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The `GDAXBrokerageModel` doesn't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The `GDAXBrokerageModel` uses the ImmediateFillModel .

Slippage

The `GDAXBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
PY
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `GDAXBrokerageModel` uses the GDAXFeeModel .

Buying Power

The `GDAXBrokerageModel` uses the `CashBuyingPowerModel` . The brokerage model doesn't currently support margin trading.

Settlement

The `GDAXBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `GDAXBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `GDAXBrokerageModel` is `Market.GDAX` .

Supported Models

Interactive Brokers

Introduction

This page explains `InteractiveBrokersBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.InteractiveBrokersBrokerage, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.InteractiveBrokersBrokerage, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `InteractiveBrokersBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Forex
- Futures
- Future Options
- Indices
- Index Options

Orders

The `InteractiveBrokersBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the order types that the `InteractiveBrokersBrokerageModel` supports: supports. For specific details about each order type, refer to the IB documentation.

Order Type	IB Documentation Page
MarketOrder	Market Orders
LimitOrder	Limit Orders
LimitIfTouchedOrder	Limit if Touched Orders
StopMarketOrder	Stop Orders
StopLimitOrder	Stop-Limit Orders
MarketOnOpenOrder	Market-on-Open (MOO) Orders
MarketOnCloseOrder	Market-on-Close (MOC) Orders
ComboMarketOrder	Spread Orders
ComboLimitOrder	Spread Orders
ComboLegLimitOrder	Spread Orders
ExerciseOption	Options Exercise

The following table describes the available order types for each asset class that the `InteractiveBrokersBrokerageModel` supports:

Order Type	US Equity	Equity Options	Forex	Futures	Futures Options	Index Options
MarketOrder	✓	✓	✓	✓	✓	✓
LimitOrder	✓	✓	✓	✓	✓	✓
LimitIfTouchedOrder	✓	✓	✓	✓	✓	✓
StopMarketOrder	✓	✓	✓	✓	✓	✓
StopLimitOrder	✓	✓	✓	✓	✓	✓
MarketOnOpenOrder	✓	✓	✓			✓
MarketOnCloseOrder	✓	✓	✓	✓	✓	✓
ComboMarketOrder		✓			✓	✓
ComboLimitOrder		✓			✓	✓
ComboLegLimitOrder		✓			✓	✓
ExerciseOption		✓ Not supported for cash-settled Options			✓	

Order Properties

The `InteractiveBrokersBrokerageModel` supports custom order properties. The following table describes the members of the `InteractiveBrokersOrderProperties` object that you can set to customize order execution. The table does not include the preceding methods for FA accounts.

Property	Description
`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`
`OutsideRegularTradingHours`	A flag to signal that the order may be triggered and filled outside of regular trading hours.

```py
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = InteractiveBrokersOrderProperties()
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled
    self.DefaultOrderProperties.OutsideRegularTradingHours = False

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = InteractiveBrokersOrderProperties()
    order_properties.TimeInForce = TimeInForce.Day
    order_properties.OutsideRegularTradingHours = True
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    order_properties.TimeInForce = TimeInForce.GoodTilDate(datetime(year, month, day))
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The `InteractiveBrokersBrokerageModel` supports order updates .

Financial Advisor Group Orders

To place FA group orders, see Financial Advisors .

Fractional Trading

The `InteractiveBrokersBrokerageModel` doesn't support fractional trading .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Order Size Limits

The `InteractiveBrokersBrokerageModel` enforces the Spot Currency Minimum/Maximum Order Sizes from the IB website.

Fills

The following table shows the fill model that the `InteractiveBrokersBrokerageModel` uses for each `SecurityType` :

SecurityType	Fill Model
Equity	EquityFillModel
Future	FutureFillModel
FutureOption	FutureOptionFillModel
Remaining SecurityType values	ImmediateFillModel

Slippage

The InteractiveBrokersBrokerageModel uses the ConstantSlippageModel with zero slippage.

```
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The InteractiveBrokersBrokerageModel uses the InteractiveBrokersFeeModel with the default argument values. We model current Interactive Brokers fees on all assets.

Buying Power

The InteractiveBrokersBrokerageModel sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equity Options	OptionMarginModel
Futures	FutureMarginModel
Future Options	FuturesOptionsMarginModel
Index Options	OptionMarginModel
Crypto	CashBuyingPowerModel for cash accounts or SecurityMarginModel for margin accounts
CryptoFuture	CryptoFutureMarginModel
Forex	CashBuyingPowerModel for cash accounts or SecurityMarginModel for margin accounts
Other	SecurityMarginModel

If you have a margin account, the InteractiveBrokersBrokerageModel allows 2x leverage for Equities, 50x leverage for Forex, and 1x leverage for the remaining asset classes.

Settlement

The `InteractiveBrokersBrokerageModel` uses the ImmediateSettlementModel in most cases. If you trade US Equities or Equity Options with a cash account, it uses the DelayedSettlementModel with the default settlement rules .

The following table shows which settlement model the `InteractiveBrokersBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `InteractiveBrokersBrokerageModel` uses the ImmediateSettlementModel .

```py
# For US Equities with a cash account:
security.SettlementModel = DelayedSettlementModel(Equity.DefaultSettlementDays,
Equity.DefaultSettlementTime)

# For Equity Options with a cash account:
security.SettlementModel = DelayedSettlementModel(Option.DefaultSettlementDays,
Option.DefaultSettlementTime)

# For remaining cases:
security.SettlementModel = ImmediateSettlementModel()
```

Interactive Brokers doesn't provide information on which assets aren't settled, so we assume each live trading session starts with its cash fully settled.

Margin Interest Rate

The `InteractiveBrokersBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `InteractiveBrokersBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA
Forex	Oanda

Financial Advisors

IB supports FA accounts for Trading Firm and Institution organizations. FA accounts enable certified professionals to use a single trading algorithm to manage several client accounts.

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```
self.DefaultOrderProperties = InteractiveBrokersOrderProperties()
self.DefaultOrderProperties.FaGroup = "TestGroupEQ"
self.DefaultOrderProperties.FaMethod = "EqualQuantity"
self.DefaultOrderProperties.FaProfile = "TestProfileP"
self.DefaultOrderProperties.Account = "DU123456"
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `self.Portfolio["SPY"].Quantity` is zero.

The following table shows the supported allocation methods for FA group orders:

FaMethod	Description
"EqualQuantity"	Distributes shares equally between all accounts in the group. If you use this method, specify an order quantity.
"NetLiq"	Distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net liquidation value in each account and allocates shares based on these ratios. If you use this method, specify an order quantity.
"AvailableEquity"	Distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. If you use this method, specify an order quantity.
"PctChange"	Increases or decreases an already existing position. Positive percents increase positions and negative percents decrease positions. If you use this method, specify a percent instead of an order quantity.

PY

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = InteractiveBrokersOrderProperties()
    self.DefaultOrderProperties.FaGroup = "TestGroupEQ"
    self.DefaultOrderProperties.FaMethod = "EqualQuantity"
    self.DefaultOrderProperties.FaProfile = "TestProfileP"
    self.DefaultOrderProperties.Account = "DU123456"

def OnData(self, slice: Slice) -> None:
    # Override the default order properties
    # "NetLiq" requires a order size input
    order_properties = InteractiveBrokersOrderProperties()
    order_properties.FaMethod = "NetLiq"
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    # "AvailableEquity" requires a order size input
    order_properties.FaMethod = "AvailableEquity"
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    # "PctChange" requires a percentage of portfolio input
    order_properties.FaMethod = "PctChange"
    self.SetHoldings(self.symbol, pct_portfolio, orderProperties=order_properties)
```

Supported Models

Kraken

Introduction

This page explains `KrakenBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.Kraken, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `KrakenBrokerageModel` supports trading Crypto .

Orders

The `KrakenBrokerageModel` supports several order types and order properties, but it doesn't support order updates.

Order Types

The following table describes the available order types for each asset class that the `KrakenBrokerageModel` supports:

Order Type	Crypto
MarketOrder	✓
LimitOrder	✓
LimitIfTouchedOrder	✓
StopMarketOrder	✓
StopLimitOrder	✓

Order Properties

The `KrakenBrokerageModel` supports custom order properties. The following table describes the members of the `KrakenOrderProperties` object that you can set to customize order execution:

Property	Description
`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`
`PostOnly`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.
`FeeInBase`	A flag to signal that the order fees should be paid in the base currency, which is the default behavior when selling. This flag must be the opposite of the `FeeInQuote` flag.
`FeeInQuote`	A flag to signal that the order fees should be paid in the quote currency, which is the default behavior when buying. This flag must be the opposite of the `FeeInBase` flag.
`NoMarketPriceProtection`	A flag to signal that no Market Price Protection should be used.
`ConditionalOrder`	An `Order` that's submitted when the primary order is executed. The `ConditionalOrder` quantity must match the primary order quantity and the `ConditionalOrder` direction must be the opposite of the primary order direction. This order property is only available for live algorithms.

PY

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = KrakenOrderProperties()
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled
    self.DefaultOrderProperties.PostOnly = False
    self.DefaultOrderProperties.FeeInBase = True
    self.DefaultOrderProperties.FeeInQuote = False
    self.DefaultOrderProperties.NoMarketPriceProtection = True

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = KrakenOrderProperties()
    order_properties.TimeInForce = TimeInForce.Day
    order_properties.PostOnly = True
    order_properties.FeeInBase = False
    order_properties.FeeInQuote = True
    order_properties.NoMarketPriceProtection = True
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    order_properties.TimeInForce = TimeInForce.GoodTilDate(datetime(year, month, day))
    order_properties.PostOnly = False
    order_properties.FeeInBase = True
    order_properties.FeeInQuote = False
    order_properties.NoMarketPriceProtection = False
    order_properties.ConditionalOrder = StopLimitOrder(self.symbol, -quantity, stop_limit_price,
stop_price)
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The `KrakenBrokerageModel` doesn't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages

That Don't Support Updates .

Fills

The `KrakenBrokerageModel` uses the ImmediateFillModel .

Slippage

The `KrakenBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
PY
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `KrakenBrokerageModel` uses the KrakenFeeModel .

Buying Power

The `KrakenBrokerageModel` uses the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

If you have a margin account, the `KrakenBrokerageModel` allows 1x leverage for most Crypto pairs. The following table shows pairs that have additional leverage available:

Quote Currency	Base Currencies	Leverage
ADA	BTC, ETH, USD, EUR	3
BCH	BTC, USD, EUR	2
BTC	USD, EUR	5
DASH	BTC, USD, EUR	3
EOS	BTC, ETH, USD, EUR	3
ETH	BTC, USD, EUR	5
LINK	BTC, ETH, USD, EUR	3
LTC	BTC, USD, EUR	3
REP	BTC, ETH, USD, EUR	2
TRX	BTC, ETH, USD, EUR	3
USDC	USD, EUR	3
USDT	USD, EUR	2
XMR	BTC, USD, EUR	2
XRP	BTC, USD, EUR	3
XTZ	BTC, ETH, USD, EUR	2

Settlement

The `KrakenBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `KrakenBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `KrakenBrokerageModel` is `Market.Kraken` .

Supported Models

Oanda

Introduction

This page explains `OandaBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.OandaBrokerage, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `OandaBrokerageModel` supports trading Forex and CFDs .

Orders

The `OandaBrokerageModel` supports several order types, the `TimeInForce` order property, and order updates.

Order Types

The following table describes the available order types for each asset class that the `OandaBrokerageModel` supports:

Order Type	Forex	CFD
MarketOrder	✓	✓
LimitOrder	✓	✓
StopMarketOrder	✓	✓

Time In Force

The `OandaBrokerageModel` the `GoodTilCanceled` TimeInForce .

```
self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled
self.LimitOrder(self.symbol, quantity, limit_price)
```

Updates

The `OandaBrokerageModel` supports order updates .

Fills

The `OandaBrokerageModel` uses the ImmediateFillModel .

Slippage

The `OandaBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
security.SetSlippageModel(ConstantSlippageModel(0))
```
PY

Fees

The `OandaBrokerageModel` uses the ConstantFeeModel with zero fees. OANDA offers "Spread" and "Core + Commission" pricing models. Our data is the spread dataset, so we model the spread pricing. To estimate OANDA Core+Commission data, use a custom fee model and a custom fill model .

```
security.SetFeeModel(ConstantFeeModel(0))
```
PY

Buying Power

The `OandaBrokerageModel` uses the `SecurityMarginModel` and allows up to 50x leverage.

Settlement

The `OandaBrokerageModel` uses the ImmediateSettlementModel for Forex trades and the AccountCurrencyImmediateSettlementModel for CFD trades.

Margin Interest Rate

The `OandaBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `OandaBrokerageModel` is `Market.Oanda` .

Supported Models

Samco

Introduction

This page explains `SamcoBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.Samco, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.Samco, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `SamcoBrokerageModel` supports trading the following asset classes:

- Indian Equities
- India Equity Options
- India Futures

Orders

The `SamcoBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `SamcoBrokerageModel` supports:

Order Type	India Equity
MarketOrder	✓
LimitOrder	✓
StopMarketOrder	✓

Order Properties

The `SamcoBrokerageModel` supports custom order properties. The following table describes the members of the `IndiaOrderProperties` object that you can set to customize order execution:

Property	Description
`Exchange`	Select the exchange for sending the order to. The following instructions are available: • `NSE` • `BSE`
`ProductType`	A `ProductType` instruction to apply to the order. The `IndiaProductType` enumeration has the following members:
`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are available: • `Day` • `GoodTilCanceled` • `GoodTilDate`

PY

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = IndiaOrderProperties(Exchange.NSE,
IndiaOrderProperties.IndiaProductType.NRML)
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = IndiaOrderProperties(Exchange.BSE, IndiaOrderProperties.IndiaProductType.MIS)
    order_properties.TimeInForce = TimeInForce.Day
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    order_properties = IndiaOrderProperties(Exchange.BSE, IndiaOrderProperties.IndiaProductType.CNC)
    order_properties.TimeInForce = TimeInForce.GoodTilDate
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The `SamcoBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The `SamcoBrokerageModel` uses the EquityFillModel .

Slippage

The `SamcoBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
PY
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `SamcoBrokerageModel` uses the SamcoFeeModel .

Buying Power

The `SamcoBrokerageModel` uses the `SecurityMarginModel` . If you have a margin account, the `SamcoBrokerageModel` allows up to 5x leverage.

Settlement

The `SamcoBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```
PY
# For cash accounts:
security.SettlementModel = DelayedSettlementModel(Equity.DefaultSettlementDays,
Equity.DefaultSettlementTime)

# For margin accounts:
security.SettlementModel = ImmediateSettlementModel()
```

Margin Interest Rate

The `SamcoBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `SamcoBrokerageModel` is `Market.India` .

Supported Models

TD Ameritrade

Introduction

This page explains `TDAmeritradeBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```py
self.SetBrokerageModel(BrokerageName.TDAmeritrade, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.TDAmeritrade, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `TDAmeritradeBrokerageModel` supports trading US Equities .

Orders

The `TDAmeritradeBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `TDAmeritradeBrokerageModel` supports:

Order Type	Equity
MarketOrder	✓
LimitOrder	✓
StopMarketOrder	✓
StopLimitOrder	✓

Time In Force

The `TDAmeritradeBrokerageModel` supports the following TimeInForce instructions:

- `Day`
- `GoodTilCanceled`
- `GoodTilDate`

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = TDAmeritradeOrderProperties()
    order_properties.TimeInForce = TimeInForce.Day
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    order_properties.TimeInForce = TimeInForce.GoodTilDate(datetime(year, month, day))
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The `TDAmeritradeBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The `TDAmeritradeBrokerageModel` uses the EquityFillModel .

Slippage

The `TDAmeritradeBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `TDAmeritradeBrokerageModel` uses the TDAmeritradeFeeModel .

Buying Power

The `TDAmeritradeBrokerageModel` uses the `SecurityMarginModel` . If you have a margin account, the `TDAmeritradeBrokerageModel` allows up to 2x leverage.

Settlement

The `TDAmeritradeBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```
# For cash accounts:
security.SettlementModel = DelayedSettlementModel(Equity.DefaultSettlementDays,
Equity.DefaultSettlementTime)

# For margin accounts:
security.SettlementModel = ImmediateSettlementModel()
```

Margin Interest Rate

The `TDAmeritradeBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `TDAmeritradeBrokerageModel` is `Market.USA` .

Supported Models

Tradier

Introduction

This page explains `TradierBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.TradierBrokerage, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.TradierBrokerage, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `TradierBrokerageModel` supports trading US Equities and Equity Options .

Orders

The `TradierBrokerageModel` supports several order types, order properties, and most order updates.

Order Types

The following table describes the available order types for each asset class that the `TradierBrokerageModel` supports:

Order Type	Equity	Equity Options
MarketOrder	✓	✓
LimitOrder	✓	✓
StopMarketOrder	✓	✓
StopLimitOrder	✓	✓

Time In Force

The `TradierBrokerageModel` supports the following TimeInForce instructions:

- `Day`
- `GoodTilCanceled` (not available for short selling)
- `GoodTilDate`

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = OrderProperties()
    order_properties.TimeInForce = TimeInForce.Day
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    order_properties.TimeInForce = TimeInForce.GoodTilDate(datetime(year, month, day))
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

PY

Updates

The `TradierBrokerageModel` supports most order updates . To update the quantity of an order, cancel the order and then submit a new order with the desired quantity. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Extended Market Hours

The `TradierBrokerageModel` doesn't support extended market hours trading. If you place an order outside of regular trading hours, the order will be processed at market open.

Automatic Cancellations

If you have open orders for a security when it performs a reverse split, the `TradierBrokerageModel` automatically cancels your orders.

Errors

To view the order-related error codes from Tradier, see Error Responses in their documentation.

The `TradierBrokerageModel` validates your orders for the following errors before sending them to Tradier:

Error	Description
`ShortOrderIsGtc`	You can't short sell with the `GoodTilCanceled` time in force
`SellShortOrderLastPriceBelow5`	You can't short sell stocks below $5
`IncorrectOrderQuantity`	The order quantity must be between 1 and 10,000,000 shares

Fills

The `TradierBrokerageModel` uses the EquityFillModel for Equity trades and the ImmediateFillModel for Option trades.

Slippage

The `TradierBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `TradierBrokerageModel` uses the ConstantFeeModel with zero fees.

```
security.SetFeeModel(ConstantFeeModel(0))
```

Buying Power

The `TradierBrokerageModel` uses the `OptionMarginModel` for Option trades and the `SecurityMarginModel` for Equity trades.

If you have a margin account, the `TradierBrokerageModel` allows 2x leverage for Equities.

Settlement

The `TradierBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```
# For US Equities with a cash account:
security.SettlementModel = DelayedSettlementModel(Equity.DefaultSettlementDays,
Equity.DefaultSettlementTime)

# For Equity Options with a cash account:
security.SettlementModel = DelayedSettlementModel(Option.DefaultSettlementDays,
Option.DefaultSettlementTime)

# For remaining cases:
security.SettlementModel = ImmediateSettlementModel()
```

Margin Interest Rate

The `TradierBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `TradierBrokerageModel` is `Market.USA` .

Supported Models

Trading Technologies

Introduction

This page explains `TradingTechnologiesBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```py
self.SetBrokerageModel(BrokerageName.TradingTechnologies, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.TradingTechnologies, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `TradingTechnologiesBrokerageModel` supports trading Futures .

Orders

The `TradingTechnologiesBrokerageModel` supports several order types, some `TimeInForce` order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `TradingTechnologiesBrokerageModel` supports:

Order Type	Futures
MarketOrder	✓
LimitOrder	✓
StopMarketOrder	✓
StopLimitOrder	✓

The `TradingTechnologiesBrokerageModel` enforces the following order rules:

- If you are buying (selling) with a `StopMarketOrder` or a `StopLimitOrder` , the stop price of the order must be greater (less) than the current security price.
- If you are buying (selling) with a `StopLimitOrder` , the limit price of the order must be greater (less) than the stop price.

Time In Force

The `TradingTechnologiesBrokerageModel` supports the `Day` and `GoodTilCanceled` TimeInForce order properties.

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = OrderProperties()
    order_properties.TimeInForce = TimeInForce.Day
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The `TradingTechnologiesBrokerageModel` supports order updates .

Fills

The `TradingTechnologiesBrokerageModel` uses the FutureFillModel .

Slippage

The `TradingTechnologiesBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `TradingTechnologiesBrokerageModel` uses the ConstantFeeModel with zero fees.

```
security.SetFeeModel(ConstantFeeModel(0))
```

Buying Power

The `TradingTechnologiesBrokerageModel` uses the `FutureMarginModel` .

Settlement

The `TradingTechnologiesBrokerageModel` uses the FutureSettlementModel .

Margin Interest Rate

The `TradingTechnologiesBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `TradierBrokerageModel` is `Market.CME` .

Supported Models

Wolverine

Introduction

This page explains `WolverineBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.Wolverine, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.Wolverine, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `WolverineBrokerageModel` supports trading US Equities .

Orders

The `WolverineBrokerageModel` supports one order type, but doesn't support order updates or extended market hours trading.

Order Types

The `WolverineBrokerageModel` supports market orders .

Updates

The `WolverineBrokerageModel` doesn't support order updates.

Extended Market Hours

The `WolverineBrokerageModel` doesn't support extended market hours trading. If you place an order outside of regular trading hours, the order is invalid.

Fills

The `WolverineBrokerageModel` uses the EquityFillModel for Equity trades.

Slippage

The `WolverineBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `WolverineBrokerageModel` uses the WolverineFeeModel .

Buying Power

The `WolverineBrokerageModel` uses the `SecurityMarginModel` . If you have a margin account, the `WolverineBrokerageModel` allows up to 2x leverage.

Settlement

The `WolverineBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```py
# For cash accounts:
security.SettlementModel = DelayedSettlementModel(Equity.DefaultSettlementDays,
Equity.DefaultSettlementTime)

# For margin accounts:
security.SettlementModel = ImmediateSettlementModel()
```

Margin Interest Rate

The `WolverineBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `WolverineBrokerageModel` is `Market.USA` .

Supported Models

Zerodha

Introduction

This page explains `ZerodhaBrokerageModel` , including the asset classes it supports, its default security-level models , and it's default markets.

```
self.SetBrokerageModel(BrokerageName.Zerodha, AccountType.Cash)
self.SetBrokerageModel(BrokerageName.Zerodha, AccountType.Margin)
```

To view the implementation of this model, see the LEAN GitHub repository .

Asset Classes

The `ZerodhaBrokerageModel` supports trading Indian Equities .

Orders

We model the Zerodha API by supporting several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `ZerodhaBrokerageModel` supports:

Order Type	India Equity
MarketOrder	✓
LimitOrder	✓
StopMarketOrder	✓
StopLimitOrder	✓

Order Properties

The `ZerodhaBrokerageModel` supports custom order properties. The following table describes the members of the `IndiaOrderProperties` object that you can set to customize order execution:

Property	Description
`Exchange`	Select the exchange for sending the order to. The following instructions are supported: • `NSE` • `BSE`
`ProductType`	A `ProductType` instruction to apply to the order. The `IndiaProductType` enumeration has the following members:
`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`

```py
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = IndiaOrderProperties(Exchange.NSE,
IndiaOrderProperties.IndiaProductType.NRML)
    self.DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled

def OnData(self, slice: Slice) -> None:
    # Use default order order properties
    self.LimitOrder(self.symbol, quantity, limit_price)

    # Override the default order properties
    order_properties = IndiaOrderProperties(Exchange.BSE, IndiaOrderProperties.IndiaProductType.MIS)
    order_properties.TimeInForce = TimeInForce.Day
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    order_properties = IndiaOrderProperties(Exchange.BSE, IndiaOrderProperties.IndiaProductType.CNC)
    order_properties.TimeInForce = TimeInForce.GoodTilDate
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)
```

Updates

The `ZerodhaBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The `ZerodhaBrokerageModel` uses the EquityFillModel .

Slippage

The `ZerodhaBrokerageModel` uses the ConstantSlippageModel with zero slippage.

```
PY
security.SetSlippageModel(ConstantSlippageModel(0))
```

Fees

The `ZerodhaBrokerageModel` uses the ZerodhaFeeModel .

Buying Power

The `ZerodhaBrokerageModel` uses the `SecurityMarginModel` . If you have a margin account, the `ZerodhaBrokerageModel` allows up to 5x leverage.

Settlement

The `ZerodhaBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```
PY
# For cash accounts:
security.SettlementModel = DelayedSettlementModel(Equity.DefaultSettlementDays,
Equity.DefaultSettlementTime)

# For margin accounts:
security.SettlementModel = ImmediateSettlementModel()
```

Margin Interest Rate

The `ZerodhaBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `ZerodhaBrokerageModel` is `Market.India` .

Reality Modeling

Buying Power

Introduction

Buying power models (also known as margin models) control how much buying power or leverage your portfolio has to make trades. When you place an order, LEAN uses the buying power model to determine whether the order should be submitted so you avoid placing orders that would be rejected by the brokerage. Buying power calculations can be very complex and depend on many factors, including the brokerage or even the time of day. For example, the `PatternDayTradingMarginModel` lets you have 4x leverage during regular trading hours and 2x leverage during pre-market and post-market trading hours.

What is Buying Power?

Buying power is the total amount of money you can spend in your brokerage account. It depends on the security type and account type. On one hand, Option and Future contracts are leveraged securities with specific buying power rules. On the other hand, the buying power of cash accounts is just the cash in the account while the buying power of margin accounts is leveraged by the brokerage credit.

What is Margin?

Margin is a credit loan from your brokerage you receive after you deposit collateral into your margin account. You need margin to place short-biased trades and you can use margin to increase your buying power, but you incur interest fees. **Margin** is the dollar value of the loan that the brokerage gives you. A **margin requirement** of 25% means that to purchase 10,000 worth of securities, you need at least 2,500 worth of collateral in your brokerage account to open the trade and you can borrow the rest on margin. **Maintenance margin** is the minimum equity (equity = total portfolio value - borrowed funds) you must have in your brokerage account to stay in your positions. If the value of your portfolio falls below the maintenance margin, you receive a margin call . If you receive a margin call, you either need to add more capital to your brokerage account or the brokerage will liquidate some of your holdings to reduce your exposure and their risk.

Some securities have special margin rules. Derivatives are leveraged assets with a floating margin requirement. In particular, long Options have zero maintenance margin requirement and their initial margin requirement is only the premium that you pay upfront.

What is Leverage?

Leverage is using borrowed money to increase your buying power. Leverage has an inverse relationship with your margin requirement and maintenance margin. If you have a margin requirement of 50%, you can use up to 1 / 50% = 2 leverage. Trading with leverage can be risky. It can boost your returns on profitable trades but can make your losing trades more expensive. If you have 10,000 in your brokerage margin account and purchase 20,000 worth of securities, you are trading with 2x leverage. If the value of the securities in your portfolio drops by 50% when you have a 2x leverage position, you lose all of your equity.

What Are Position Groups?

A position group is the combination of holdings. It has lower margin requirement and maintenance margin than the sum of each position of the group. If you have a margin requirement of 29,150 to purchase an in-the-money call Option contract, and a margin requirement of 101,499 to sell an out-of-the money call Option contract, the total margin requirement is $130,649. However, these positions compose a bull call spread with a margin requirement of $0.

Set Models

The brokerage model of your algorithm automatically sets the buying power model for each security, but you can override it. To manually set the buying power model of a security, call the `SetBuyingPowerModel` method on the `Security` object.

```
PY
# In Initialize
security = self.AddEquity("SPY")
security.SetFeeModel(SecurityMarginModel(3))
```

You can also set the buying power model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `SetSecurityInitializer` before you create the subscriptions.

```
PY
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetBuyingPowerModel(SecurityMarginModel(3))
```

You cannot change the position group buying power models.

Supported Models

The following buying power models are available:

- BuyingPowerModel
- CashBuyingPowerModel
- ConstantBuyingPowerModel
- CryptoFutureMarginModel
- NullBuyingPowerModel
- FutureMarginModel
- FuturesOptionsMarginModel

- SecurityMarginModel
- OptionMarginModel
- PatternDayTradingMarginModel

The following position group buying power models are available:

- SecurityPositionGroupBuyingPowerModel
- OptionStrategyPositionGroupBuyingPowerModel

Default Behavior

The brokerage model of your algorithm automatically sets the buying power model of each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	**Model**
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`
Future Options	`FuturesOptionsMarginModel`
Index Options	`OptionMarginModel`
Crypto	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
CryptoFuture	`CryptoFutureMarginModel`
Forex	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
Other	`SecurityMarginModel`

Model Structure

Buying power models should extend the `BuyingPowerModel` class. Extensions of the `BuyingPowerModel` class should implement the following methods:

```py
class MyBuyingPowerModel(BuyingPowerModel):
    def __init__(self,
                 leverage = 2: float,
                 requiredFreeBuyingPowerPercent = 0: float):
        super().__init__(leverage, requiredFreeBuyingPowerPercent)

    def GetLeverage(self, security: Security) -> float:
        return super().GetLeverage(security)

    def SetLeverage(self, security: Security, leverage: float) -> None:
        super().SetLeverage(security, leverage)

    def GetInitialMarginRequiredForOrder(self,
                 parameters: InitialMarginRequiredForOrderParameters) -> InitialMargin:
        return super().GetInitialMarginRequiredForOrder(parameters)

    def GetMaintenanceMargin(self,
                 parameters: MaintenanceMarginParameters) -> MaintenanceMargin:
        return super().GetMaintenanceMargin(parameters)

    def GetMarginRemaining(self,
                 portfolio: SecurityPortfolioManager,
                 security: Security,
                 direction: OrderDirection) -> float:
        return super().GetMarginRemaining(portfolio, security, direction)

    def GetInitialMarginRequirement(self,
                 parameters: InitialMarginParameters) -> InitialMargin:
        return super().GetInitialMarginRequirement(parameters)

    def HasSufficientBuyingPowerForOrder(self,
                 parameters: HasSufficientBuyingPowerForOrderParameters
        ) -> HasSufficientBuyingPowerForOrderResult:
        return super().HasSufficientBuyingPowerForOrder(parameters)

    def GetMaximumOrderQuantityForDeltaBuyingPower(self,
                 parameters: GetMaximumOrderQuantityForDeltaBuyingPowerParameters
        ) -> GetMaximumOrderQuantityResult:
        return super().GetMaximumOrderQuantityForDeltaBuyingPower(parameters)

    def GetMaximumOrderQuantityForTargetBuyingPower(self,
                 parameters: GetMaximumOrderQuantityForTargetBuyingPowerParameters
        ) -> GetMaximumOrderQuantityResult:
        return super().GetMaximumOrderQuantityForTargetBuyingPower(parameters)

    def GetReservedBuyingPowerForPosition(self,
                 parameters: ReservedBuyingPowerForPositionParameters
        ) -> ReservedBuyingPowerForPosition:
        return super().GetReservedBuyingPowerForPosition(parameters)

    def GetBuyingPower(self,
                 parameters: BuyingPowerParameters) -> BuyingPower:
        return super().GetBuyingPower(parameters)
```

Disable Buying Power

You can disable order margin checks and opt to let your brokerage decide to accept or reject the trades. This is helpful in live trading if you have a more permissive brokerage margin allowance that what LEAN models. The default position group buying power models are helpful for Option trading strategies. However, it can be counterproductive if it's not a supported Option strategy . To disable the validations of the default position group buying power model, use the `NullSecurityPositionGroupModel` . To set the `NullSecurityPositionGroupModel` for the portfolio, during initialization , call the `SetPositions` method with the `SecurityPositionGroupModel.Null` argument.

```py
self.Portfolio.SetPositions(SecurityPositionGroupModel.Null)
```

To disable the validations of the default buying power model , use the `NullBuyingPowerModel` . To set the `NullBuyingPowerModel` for a security subscription, call the `SetBuyingPowerModel` method with the `BuyingPowerModel.Null` argument.

```
PY
equity = self.AddEquity("SPY")
equity.SetBuyingPowerModel(BuyingPowerModel.Null)
# Alias:
# equity.SetMarginModel(SecurityMarginModel.Null)
```

You can also set the asset `NullBuyingPowerModel` in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to set the buying power of securities in the security initializer, call `SetSecurityInitializer` before you create security subscriptions and after you call `SetBrokerageModel` .

```
PY
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite the security buying power
        security.SetBuyingPowerModel(BuyingPowerModel.Null)
```

Set Asset Leverage

The buying power model sets the leverage for each security in your algorithm, but you can override its leverage settings after the buying power model is set.

To set the leverage when you create a security subscription, pass in a `leverage` argument.

```
PY
# In Initialize
AddEquity("SPY", leverage=3)
```

You can also set the asset leverage in a security initializer. In order to set the leverage of securities in the security initializer, call `SetSecurityInitializer` before you create security subscriptions and before you call `SetBrokerageModel` . If you pass in a `leverage` argument when you create the security subscription, the `leverage` argument takes precedence over the `SetLeverage` call in the security initializer.

```
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite the security leverage
        security.SetLeverage(3)
```

To set the leverage for all securities in a universe, set the `UniverseSettings.Leverage` property.

```
# In Initialize
self.UniverseSettings.Leverage = 3
```

In live trading, LEAN doesn't ignore the leverage you set. However, if you set a different leverage from what your brokerage provides, it creates a mismatch between the buying power in your algorithm and the buying power the brokerage gives you. In this case, orders can pass the validations in LEAN but your brokerage may reject them.

PDT Rule

If all of the following statements are true, you are classified as a pattern day trader:

- You reside in the United States.
- You trade in a margin account.
- You execute 4+ intraday US Equity trades within 5 business days.
- Your intraday US Equity trades represent more than 6% of your total trades.

Pattern day traders must maintain a minimum equity of $25,000 in their margin account to continue trading. For more information about pattern day trading, see Am I a Pattern Day Trader? on the FINRA website.

The `PatternDayTradingMarginModel` doesn't enforce minimum equity rules and doesn't limit your trades, but it adjusts your available leverage based on the market state. During regular market hours, you can use up to 4x leverage. During extended market hours, you can use up to 2x leverage.

```
security.MarginModel = PatternDayTradingMarginModel()
```

Reality Modeling

Settlement

Settlement

Key Concepts

Introduction

After you trade an asset, the brokerage needs to settle the funds in your account. The most common type of settlement is immediate, where the funds are immediately available for trading after the transaction. In some cases, you may have delayed settlement, where you sell an asset and need to wait a few days to spend the cash you receive from the sale. A settlement model simulates these settlement rules.

Set Models

The brokerage model of your algorithm automatically sets the settlement model for each security, but you can override it. To manually set the settlement model of a security, set the `SettlementModel` property on the `Security` object.

```
PY
# In Initialize
security = self.AddEquity("SPY")
# Set a delayed settlement model that settles 7 days after the trade at 8 AM
security.SettlementModel = DelayedSettlementModel(7, timedelta(hours=8))
```

You can also set the settlement model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `SetSecurityInitializer` before you create the subscriptions.

```
PY
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SettlementModel = DelayedSettlementModel(7, timedelta(hours=8))
```

To view all the pre-built settlement models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the settlement model for each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the settlement model based on the security type and your account type. The following table shows how it sets the settlement models:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `DefaultBrokerageModel` uses the ImmediateSettlementModel .

The default delayed settlement rule for US Equity trades is T+2 at 8 AM Eastern Time (ET). For example, if you sell on Monday, the trade settles on Wednesday at 8 AM. The default delayed settlement rule for Future and Option contracts is T+1 at 8 AM.

Model Structure

Settlement models must extend the `ISettlementModel` interface. Extensions of the `ISettlementModel` interface must implement the `Scan` and `ApplyFunds` methods. The `Scan` method is automatically called at the top of each hour and it receives a `ScanSettlementModelParameters` object. The `ApplyFunds` method receives an `ApplyFundsSettlementModelParameters` object and applies the settlement rules. The `ApplyFunds` method is also automatically called, but its frequency depends on the security type.

The `ApplyFunds` method is automatically called when you fill an order for the following security types:

- Equity
- Equity Options
- Crypto
- Forex
- Future Options
- Index Options

The `ApplyFunds` method is automatically called when you close a position for the following security types:

- Futures
- Crypto Futures
- CFD

`ApplyFundsSettlementModelParameters` objects have the following properties:

`ScanSettlementModelParameters` objects have the following properties:

You likely don't need to create a custom settlement model because the supported models already implement immediate and delayed settlement rules.

Settlement

Supported Models

Introduction

This page describes all of the pre-built settlement models in LEAN. For more brokerage-specific settlement models, see the brokerage model documentation . If none of these models perform exactly how you want, create a custom settlement model .

Immediate Model

The `ImmediateSettlementModel` immediately adds or removes the cash from your portfolio when your transactions fill.

```
security.SettlementModel = ImmediateSettlementModel()
```

To view the implementation of this model, see the LEAN GitHub repository .

Delayed Model

The `DelayedSettlementModel` immediately removes the cash from your portfolio when your buy orders fill. When your sell orders fill, it adds the cash to your unsettled cash book . When the settlement period ends, the unsettled cash is added to your portfolio.

```
security.SettlementModel = DelayedSettlementModel(7, timedelta(hours=8))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`numberOfDays`	`int`	The number of days required for settlement	
`timeOfDay`	`timedelta`	The time of day used for settlement	

To view the implementation of this model, see the LEAN GitHub repository .

Account Currency Immediate Model

The `AccountCurrencyImmediateSettlementModel` applies cash settlement immediately and automatically converts the settlement cash into the account currency.

```
security.SettlementModel = AccountCurrencyImmediateSettlementModel()
```

To view the implementation of this model, see the LEAN GitHub repository .

Future Model

The `FutureSettlementModel` settles the daily profit and loss at the start of each day.

```
security.SettlementModel = FutureSettlementModel()
```

PY

To view the implementation of this model, see the LEAN GitHub repository .

Reality Modeling

Options Models

Options Models

Pricing

Introduction

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

What are Greeks?

Option Greeks measure the exposure of Option price or Option delta to the movement of different factors such as the underlying price, time, and volatility. The Greeks are a function of implied volatility. For more information about them, see The Greek Letters .

What Is Implied Volatility?

Implied volatility is the forecasted future volatility of a security. The Option price model uses the realized volatility to calculate the implied volatility. By default, it uses the formula from Brenner and Subrahmanyam (1988) as the initial guess for implied volatility.

$$\frac{P}{S} \sqrt{\frac{2\pi}{T}}$$

where P is the Option contract price, S is the underlying price, and T is the time until Option expiration.

If the volatility model of the underlying security is ready , the price model uses its value as the initial guess for implied volatility and as an input to calculate the theoretical contract prices.

Set Models

To set the pricing model of an Option, set its `PriceModel` property.

If you have access to the `Option` object when you subscribe to the Option universe or contract, you can set the price model immediately after you create the subscription.

```py
# In Initialize
option = self.AddOption("SPY")
option.PriceModel = OptionPriceModels.CrankNicolsonFD()
```

Otherwise, set the price model in a security initializer .

```py
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite the price model
        if security.Type == SecurityType.Option: # Option type
            security.PriceModel = OptionPriceModels.CrankNicolsonFD()
```

Supported Models

LEAN supports the following Option price models. QLNet provides the underlying implementation of these models.

Model	American Style	European Style
`AdditiveEquiprobabilities`	✓	✓
`BaroneAdesiWhaley`	✓	
`BinomialCoxRossRubinstein`	✓	✓
`BinomialJarrowRudd`	✓	✓
`BinomialJoshi`	✓	✓
`BinomialLeisenReimer`	✓	✓
`BinomialTian`	✓	✓
`BinomialTrigeorgis`	✓	✓
`BjerksundStensland`	✓	
`BlackScholes`		✓
`CrankNicolsonFD`	✓	✓
`Integral`		✓

If you set the price model of an Option to a model with an incompatible style, LEAN throws an exception.

Default Behavior

The default Option pricing model is the `BjerksundStensland` for American Options or `BlackScholes` for European Options.

Disable Pricing

To turn off the Option price model, use the `CurrentPriceOptionPriceModel` . This model sets the Greeks to 0, sets the implied volatility to 0, and sets the theoretical price to the current price.

```
option.PriceModel = CurrentPriceOptionPriceModel()
```

Options Models

Volatility

Volatility

Key Concepts

Introduction

Volatility models measure the historical volatility of an asset. They are mostly used to calculate the volatility of the underlying security of an Option because the implied volatility of an Option contract needs an initial guess. The historical volatility doesn't need to be the standard deviation of the asset prices. The various volatility models in LEAN each have a unique methodology to calculate volatility.

Set Models

To set the volatility model of the underlying security of an Option, set the `VolatilityModel` property of the `Security` object. The volatility model can have a different resolution than the underlying asset subscription.

```
PY
# In Initialize
underlying_security = self.AddEquity("SPY")
underlying_security.VolatilityModel = StandardDeviationOfReturnsVolatilityModel(30)
```

You can also set the volatility model in a security initializer . If your algorithm has a universe of underlying assets, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `SetSecurityInitializer` before you create the subscriptions.

```
PY
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite the volatility model
        if security.Type == SecurityType.Equity:
            security.VolatilityModel = StandardDeviationOfReturnsVolatilityModel(30)
```

To view all the pre-built volatility models, see Supported Models .

Default Behavior

The default underlying volatility model for Equity Options and Index Options is the StandardDeviationOfReturnsVolatilityModel based on 30 days of daily resolution data. The default underlying volatility model for Future Options is the NullVolatilityModel .

Model Structure

Volatility models should extend the `BaseVolatilityModel` class. Extensions of the `BaseVolatilityModel` class must have `Update` and `GetHistoryRequirements` methods and a `Volatility` property. The `Update` method receives `Security` and `BaseData` objects and then updates the `Volatility` . The `GetHistoryRequirements` method receives `Security` and `datetime` objects and then returns a list of `HistoryRequest` objects that represent the history requests to warm up the model. Volatility models receive data at each time step in the algorithm to update their state.

```
PY
class MyVolatilityModel(BaseVolatilityModel):
    Volatility: float = 0

    def SetSubscriptionDataConfigProvider(self,
         subscriptionDataConfigProvider: ISubscriptionDataConfigProvider) -> None:
        SubscriptionDataConfigProvider = subscriptionDataConfigProvider

    def Update(self, security: Security, data: BaseData) -> None:
        pass

    def GetHistoryRequirements(self,
         security: Security,
         utcTime: datetime,
         resolution: Resolution = None,
         barCount: int = None) -> List[HistoryRequest]:
        return super().GetHistoryRequirements(security, utcTime, resolution, barCount)
```

Warm Up Models

To use your volatility model as the inital guess for the implied volatility , warm up the volatility model of the underlying security. If you subscribe to all the Options in the `Initialize` method, set a warm-up period to warm up their volatility models. The warm-up period should provide the volatility models with enough data to compute their values.

```
PY
# In Initialize
self.SetWarmUp(30, Resolution.Daily)

# In OnData
if self.IsWarmingUp:
    return
```

If you have a dynamic universe of underlying assets and add Option contracts to your algorithm with the `AddOptionContract` , `AddIndexOptionContract` , or `AddFutureOptionContract` methods, warm up the volatility model when the underlying asset enters your universe. We recommend you do this inside a security initializer .

```py
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices), self))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder, algorithm:
QCAlgorithm) -> None:
        super().__init__(brokerage_model, security_seeder)
        self.algorithm = algorithm

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite and warm up the volatility model
        if security.Type == SecurityType.Equity:  # Underlying asset type
            security.VolatilityModel = StandardDeviationOfReturnsVolatilityModel(30)
            trade_bars = self.algorithm.History[TradeBar](security.Symbol, 30, Resolution.Daily)
            for trade_bar in trade_bars:
                security.VolatilityModel.Update(security, trade_bar)
```

Demonstration Algorithms
CustomVolatilityModelAlgorithm.py Python

Volatility

Supported Models

Introduction

This page describes all of the pre-built volatility models in LEAN. If none of these models perform exactly how you want, create a custom volatility model .

Null Model

The `NullVolatilityModel` sets the volatility of the security to zero. It's the default volatility model for the underlying asset of Future Options.

```
PY
underlying_security.VolatilityModel = VolatilityModel.Null
```

To view the implementation of this model, see the LEAN GitHub repository .

Standard Deviation of Returns Model

The `StandardDeviationOfReturnsVolatilityModel` sets the volatility of the security to the annualized sample standard deviation of trailing returns. It's the default volatility model for the underlying asset of Equity Options and Index Options.

```
PY
underlying_security.VolatilityModel = StandardDeviationOfReturnsVolatilityModel(30)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`periods`	`int`	The max number of samples to use when calculating the standard deviation of returns. This value must be greater than two.	
`resolution`	`Resolution` / `NoneType`	The resolution of the price data used to calculate the standard deviation. This only has a material effect in live mode. For backtesting, this value does not cause any behavioral changes.	`None`
`updateFrequency`	`timedelta` / `NoneType`	The frequency at which new values are inserted into the rolling window for the standard deviation calculation. If the value is `None` , it defaults to the `timedelta` representation of `resolution` . If the value and `resolution` are `None` , it defaults to a `timedelta` of one day.	`None`

To view the implementation of this model, see the LEAN GitHub repository .

Relative Standard Deviation Model

The `RelativeStandardDeviationVolatilityModel` sets the volatility of the security to the relative standard deviation of its price. In symbols, the value is

$$\frac{|\mu|}{\sigma}$$

where μ is the average of the samples and σ is the standard deviation of the samples.

```
underlying_security.VolatilityModel = RelativeStandardDeviationVolatilityModel(timedelta(days=1), 10)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`periodSpan`	`timedelta`	The period of time to wait between each sample of the security price	
`periods`	`int`	The number of samples to use to calculate the volatility value	

To view the implementation of this model, see the LEAN GitHub repository .

Options Models

Exercise

Introduction

If you exercise a long Option position or are assigned on your short Option position, LEAN processes an Option exercise order. The Option exercise model converts the Option exercise order into an OrderEvent .

Set Models

To set the exercise model of an Option, call the `SetOptionExerciseModel` method of the `Option` object.

If you have access to the `Option` object when you subscribe to the Option universe or contract, you can set the exercise model immediately after you create the subscription.

```py
# In Initialize
option = AddOption("SPY")
option.SetOptionExerciseModel(DefaultExerciseModel())
```

Otherwise, set the assignment model in a security initializer .

```py
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite the exercise model
        if security.Type == SecurityType.Option: # Option type
            option.SetOptionExerciseModel(DefaultExerciseModel())
```

Default Behavior

The default Option exercise model is the `DefaultExerciseModel` . The `DefaultExerciseModel` fills exercise orders to the full quantity with zero fees and applies an order tag to represent if the order is an exercise or assignment. To view the implementation of this model, see the LEAN GitHub repository .

Model Structure

Option exercise models must implement the `OptionExercise` method, which receives `Option` and `OptionExerciseOrder` objects and then returns a list of `OrderEvent` objects that contain the order fill information.

```py
class MyExerciseModel:
    def OptionExercise(self, option: Option, order: OptionExerciseOrder) -> List[OrderEvent]:
        in_the_money = option.IsAutoExercised(option.Underlying.Close)
        is_assignment = in_the_money and option.Holdings.IsShort

        order_event = OrderEvent(
            order.Id,
            option.Symbol,
            Extensions.ConvertToUtc(option.LocalTime, option.Exchange.TimeZone),
            OrderStatus.Filled,
            Extensions.GetOrderDirection(order.Quantity),
            0.0,
            order.Quantity,
            OrderFee.Zero,
            "Tag"
        )
        order_event.IsAssignment = is_assignment
        return [ order_event ]
```

`OptionExerciseOrder` objects have the following properties:

The following table describes the arguments of the `OrderEvent` constructor:

Argument Details
Argument: `orderId` Id of the parent order Data Type: `int` | Default Value: -
Argument: `symbol` Asset Symbol Data Type: `Symbol` | Default Value: -
Argument: `utcTime` Date/time of this event Data Type: `datetime` | Default Value: -
Argument: `direction` The direction of the order. The `OrderDirection` enumeration has the following members: Data Type: `OrderDirection` | Default Value: Hold

Argument Details
Argument: `fillPrice` Fill price information if applicable Data Type: `float` | Default Value: 0
Argument: `fillQuantity` Fill quantity Data Type: `float` | Default Value: 0
Argument: `orderFee` The order fee. You can use `OrderFee.Zero` or create an `OrderFee` object with a custom fee. `OrderFee(CashAmount(0.5, 'USD'))` Data Type: `OrderFee` | Default Value: -
Argument: `message` Message from the exchange Data Type: `str` | Default Value: ""

`OrderEvent` objects have the following attributes:

Options Models

Assignment

Introduction

If you sell an Option in a backtest, an assignment model can simulate an Option exercise order on behalf of the buyer and assign you to complete the requirements of the contract.

Set Models

To set the assignment model of an Option, call the `SetOptionAssignmentModel` method of the `Option` object.

If you have access to the `Option` object when you subscribe to the Option universe or contract, you can set the assignment model immediately after you create the subscription.

```
PY
# In Initialize
option = AddOption("SPY")
option.SetOptionAssignmentModel(DefaultOptionAssignmentModel())
```

Otherwise, set the assignment model in a security initializer .

```
PY
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite the assignment model
        if security.Type == SecurityType.Option: # Option type
            option.SetOptionAssignmentModel(DefaultOptionAssignmentModel())
```

Default Behavior

The default Option assignment model is the `DefaultOptionAssignmentModel` . The `DefaultOptionAssignmentModel` scans your portfolio every hour. It considers exercising American-style Options if they are within 4 days of their expiration and it considers exercising European-style Options on their day of expiration. If you have sold an Option that's 5% in-the-money and the Option exercise order is profitable after the cost of fees, this model exercises the Option.

To view the implementation of this model, see the LEAN GitHub repository .

Model Structure

Option assignment models should implement the `IOptionAssignmentModel` interface. Extensions of the `IOptionAssignmentModel` interface must implement the `GetAssignment` method, which automatically fires at the top of each hour and returns the Option assignments to generate.

```
class MyOptionAssignmentModel:

    def GetAssignment(self, parameters: OptionAssignmentParameters) -> OptionAssignmentResult:
        option = parameters.Option
        if self.IsInTheMoney(option):
            return OptionAssignmentResult(option.Holdings.AbsoluteQuantity, "tag")
        return OptionAssignmentResult.Null
```

PY

The `OptionAssignmentParameters` object has the following members:

To exercise the Option, return an `OptionAssignmentResult` with a positive quantity. Otherwise, return `OptionAssignmentResult.Null` . The `OptionAssignmentResult` constructor accepts the following arguments:

Argument	Data Type	Description	Default Value
`quantity`	`float`	The quantity to assign	
`tag`	`str`	The order tag to use	

Disable Assignments

To disable Option assignments, set the Option assignment model to the `NullOptionAssignmentModel` .

```
option.SetOptionAssignmentModel(NullOptionAssignmentModel())
```

PY

Reality Modeling

Margin Interest Rate

Margin Interest Rate

Key Concepts

Introduction

Margin interest is a cost associated with trading on margin. Margin interest rate models model margin interest cash flows by directly adding or removing cash from your portfolio.

Set Models

The brokerage model of your algorithm automatically sets the margin interest rate model for each security, but you can override it. To manually set the margin interest rate model of a security, assign a model to the `MarginInterestRateModel` property of the Security object.

```
PY
# In Initialize
security = self.AddEquity("SPY")
security.SetMarginInterestRateModel(MarginInterestRateModel.Null)
```

You can also set the margin interest rate model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `SetSecurityInitializer` before you create the subscriptions.

```
PY
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetMarginInterestRateModel(MarginInterestRateModel.Null)
```

To view all the pre-built margin interest rate models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the margin interest rate model of each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the NullMarginInterestRateModel .

Model Structure

Margin interest rate models should implement the `IMarginInterestRateModel` interface. Extensions of the `IMarginInterestRateModel` interface must implement the `ApplyMarginInterestRate` method, which applies margin interest payments to the portfolio.

```
PY
class MyMarginInterestRateModel:

    def ApplyMarginInterestRate(self, marginInterestRateParameters: MarginInterestRateParameters) -> None:
        holdings = marginInterestRateParameters.Security.Holdings
        position_value = holdings.GetQuantityValue(holdings.Quantity)
        position_value.Cash.AddAmount(-1)
```

The `ApplyMarginInterestRate` method is automatically called at the top of each hour.

Margin Interest Rate

Supported Models

Introduction

This page describes the pre-built margin interest rate models in LEAN. If none of these models perform exactly how you want, create a custom margin interest rate model .

Null Model

The `NullMarginInterestRateModel` doesn't charge any margin interest. It's the default margin interest rate of the DefaultBrokerageModel .

```
PY
security.MarginInterestRateModel = MarginInterestRateModel.Null
```

To view the implementation of this model, see the LEAN GitHub repository .

Binance Futures Model

The `BinanceFutureMarginInterestRateModel` simulates the margin cost and payments of your Crypto Future holdings. When the funding rate is positive, the price of the perpetual contract is higher than the mark price, so traders who are long pay for short positions. Conversely, a negative funding rate indicates that perpetual prices are below the mark price, so traders who are short pay for long positions. The interest amount is

Nominal \ Value \ of \ Positions * Funding \ Rate

The interest amount is periodically credited or debited from your currency holdings while you hold open positions. The interest amount is charged at 12 AM, 8 AM, 4 PM in your algorithm time zone .

```
PY
security.MarginInterestRateModel = BinanceFutureMarginInterestRateModel()
```

To view the implementation of this model, see the LEAN GitHub repository .

Reality Modeling

Margin Calls

Introduction

If the value of your portfolio falls below the maintenance margin, you receive a margin call. If you receive a margin call, you either need to add more capital to your brokerage account or the brokerage will liquidate some of your holdings to reduce your exposure and their risk. A margin call model monitors the margin levels of your portfolio, issues margin call warnings, and submits orders when margin calls occur.

Set Models

To set the margin call model, set the `MarginCallModel` property of the `Portfolio` object.

```
PY
# In Initialize
self.Portfolio.MarginCallModel = DefaultMarginCallModel(self.Portfolio, self.DefaultOrderProperties)
```

Default Behavior

The brokerage model of your algorithm automatically sets the margin call model for the portfolio. The default brokerage model is the `DefaultBrokerageModel` , which sets the `DefaultMarginCallModel` . The `DefaultMarginCallModel` issues margin call warnings when the margin remaining in your portfolio is less than or equal to 5% of the total portfolio value. When a margin call occurs, this model sorts the generated margin call orders in ascending order by their unrealized profit and then executes each order synchronously until your portfolio is within the margin requirements.

Model Structure

Margin call models must extend the `DefaultMarginCallModel` class. Extensions of the `DefaultMarginCallModel` class can override the `GetMarginCallOrders` and `ExecuteMarginCall` methods.

The `GetMarginCallOrders` method scans the portfolio and the updated data for a potential margin call situation that may get the holdings below zero. The method must return a list of `SubmitOrderRequest` objects that represent the margin call orders. To issue a margin call warning during this method, set the `issueMarginCallWarning` argument of the method to true.

The `ExecuteMarginCall` method receives the list of `SubmitOrderRequest` objects from the `GetMarginCallOrders` method, executes some of them, and returns a list of `OrderTicket` objects.

```
class MyMarginCallModel(DefaultMarginCallModel):
    def __init__(self,
                 portfolio: SecurityPortfolioManager,
                 defaultOrderProperties: IOrderProperties):
        super().__init__(portfolio, defaultOrderProperties)

    def ExecuteMarginCall(self,
                 generatedMarginCallOrders: List[SubmitOrderRequest]) -> List[OrderTicket]:
        return super().ExecuteMarginCall(generatedMarginCallOrders)

    def GetMarginCallOrders(self,
                 issueMarginCallWarning: bool) -> List[SubmitOrderRequest]:
        return super().GetMarginCallOrders(issueMarginCallWarning)
```

PY

Disable Margin Calls

To disable margin calls, set the margin call model to the `NullMarginCallModel` .

```
self.Portfolio.MarginCallModel = MarginCallModel.Null
```

PY

Monitor Margin Call Events

When the margin call model of your portfolio issues a margin call warning, we notify your algorithm through the `OnMarginCallWarning` event handler.

```
def OnMarginCallWarning(self) -> None:
    self.Debug(f"Warning: Close to margin call")
```

PY

Before we send the orders that the margin call model produces, we notify your algorithm through the `OnMarginCall` event handler. This notification gives your algorithm a chance to liquidate some positions or modify the margin call orders. To modify the orders, adjust the list of `SubmitOrderRequest` objects the event handler receives.

```
def OnMarginCall(self, requests: List[SubmitOrderRequest]) -> List[SubmitOrderRequest]:
    for i, order in enumerate(requests):
        # liquidate an extra 10% each time you get a margin call to give yourself more padding
        new_quantity = int(order.Quantity * 1.1)
        requests[i] = SubmitOrderRequest(order.OrderType, order.SecurityType,
                                         order.Symbol, new_quantity, order.StopPrice,
                                         order.LimitPrice, 0, self.Time, "OnMarginCall")
    return requests
```

PY

Submit Order Request

If you receive a margin call or create a margin call model, you'll need to work with `SubmitOrderRequest` objects. These objects have the following properties:

The following table describes the arguments of the `SubmitOrderRequest` constructor:

Argument	Data Type	Description	Default Value
orderType	OrderType	The order type to be submitted	
securityType	SecurityType	The security type of the asset	
symbol	Symbol	The symbol to be traded	
quantity	float	The number of units to order	
stopPrice	float	The stop price for stop orders	
limitPrice	float	The limit price for limit orders	
triggerPrice	float	The trigger price for limit if touched orders	
time	datetime	The time this request was created	
tag	str	A custom tag for this request	
properties	IOrderProperties	The order properties for this request	None

MarginCallEventsAlgorithm.py Python

Scheduled Events

Introduction

Scheduled Events let you trigger code to run at specific times of day, regardless of your algorithm's data subscriptions. It's easier and more reliable to execute time-based events with Scheduled Events than checking the current algorithm time in the `OnData` event handler.

Create Scheduled Events

To create a Scheduled Event, call the `Schedule.On` method. The method expects a `DateRules` object, a `TimeRules` object, and a function to execute. The following examples demonstrate some common Scheduled Events.

Schedule Events Before Market Open

You may want to train a model or fetch historical data before the market opens. The following example demonstrates how to set a Scheduled Event for 10 minutes before the market opens.

```
PY
self.Schedule.On(self.DateRules.EveryDay("SPY"),
                 self.TimeRules.AfterMarketOpen("SPY", -10),
                 self.BeforeMarketOpen)
```

Schedule Events on the Last Trading Day of the Week

You may want to rebalance your portfolio on the last trading day of each week and factor in market holidays. The following example demonstrates how to set a Scheduled Event for the last trading day of each week 30 minutes before the market closes.

```
PY
self.Schedule.On(self.DateRules.WeekEnd("SPY"),
                 self.TimeRules.BeforeMarketClose("SPY", 30),
                 self.Rebalance)
```

Schedule Events on Regular Intervals Throughout the Trading Day

You may want to perform some action on a regular interval through each trading day. The following example demonstrates how to set a Scheduled Event for every 30 minutes through the trading day for SPY.

```
PY
self.Schedule.On(self.DateRules.EveryDay("SPY"),
                 self.TimeRules.Every(timedelta(minutes=30)),
                 self.SomeAction)
```

Date Rules

The following table describes the supported `DateRules` :

Member	Description
`self.DateRules.SetDefaultTimeZone(time_zone: DateTimeZone)`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`self.DateRules.On(year: int, month: int, day: int)`	Trigger an event on a specific date.
`self. DateRules.EveryDay()`	Trigger an event every day.
`self.DateRules.EveryDay(symbol: Symbol)`	Trigger an event every day a specific symbol is trading.
`self.DateRules.Every(days: List[DayOfWeek])`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`self.DateRules.MonthStart(daysOffset: int = 0)`	Trigger an event on the first day of each month plus an offset.
`self.DateRules.MonthStart(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`self.DateRules.MonthEnd(daysOffset: int = 0)`	Trigger an event on the last day of each month minus an offset.
`self.DateRules.MonthEnd(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`self.DateRules.WeekStart(daysOffset: int = 0)`	Trigger an event on the first day of each week plus an offset.
`self.DateRules.WeekStart(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`self.DateRules.WeekEnd(daysOffset: int = 0)`	Trigger an event on the last day of each week minus an offset.
`self.DateRules.WeekEnd(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`self. DateRules.Today`	Trigger an event once today.
`self. DateRules.Tomorrow`	Trigger an event once tomorrow.

Time Rules

The following table describes the supported `TimeRules` :

Member	Description
`self.TimeRules.SetDefaultTimeZone(time_zone: DateTimeZone)`	Sets the time zone for the `TimeRules` object used in all methods in this table, except when a different time zone is given. The default time zone is the algorithm time zone .
`self.TimeRules.AfterMarketOpen(symbol: Symbol, minutesAfterOpen: float = 0, extendedMarketOpen: bool = False)`	Trigger an event a few minutes after market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.TimeRules.BeforeMarketClose(symbol: Symbol, minutesBeforeClose: float = 0, extendedMarketOpen: bool = False)`	Trigger an event a few minutes before market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.TimeRules.Every(interval: timedelta)`	Trigger an event every period interval starting at midnight.
`self. TimeRules.Now`	Trigger an event at the current time of day.
`self. TimeRules.Midnight`	Trigger an event at midnight.
`self. TimeRules.Noon`	Trigger an event at noon.
`self.TimeRules.At(hour: int, minute: int, second: int = 0)`	Trigger an event at a specific time of day (e.g. 13:10).
`self.TimeRules.At(hour: int, minute: int, second: int, time_zone: DateTimeZone)`	Trigger an event at a specific time of day in the given time zone (e.g. 13:10 UTC).

Remove Scheduled Events

If you no longer need a Scheduled Event in your algorithm, remove it so your algorithm doesn't execute unnecessary functions. To remove a Scheduled Event, save a reference to the Scheduled Event when you create it and then call the `Remove` method to remove it.

```
# Create a Scheduled Event
scheduled_event = self.Schedule.On(self.DateRules.EveryDay("SPY"),
                                   self.TimeRules.AfterMarketOpen("SPY", 10),
                                   self.ten_minutes_after_open)

# Remove the Scheduled Event
self.Schedule.Remove(scheduled_event)
```

Common Errors

Common errors with Scheduled Events include stale fills and execution timeouts.

Stale Fills

A common error is to subscribe to daily resolution data and set a Scheduled Event intraday to place trades. If you trade

intraday with daily data, you get stale fills.

Another common error is to set a Scheduled Event to trade immediately after the market open on illiquid securities. Illiquid securities can have no trades for the first few minutes after the market open. If you trade during this time, you get stale fills.

Execution Timeouts

If your Scheduled Event takes longer than 10 minutes to execute, your algorithm will timeout. To increase the amount of time that your Scheduled Event can run, replace your Scheduled Event with a training session .

Execution Sequence

The algorithm manager calls events in the following order:

1. Scheduled Events
2. Consolidation event handlers
3. `OnData` event handler

This event flow is important to note. For instance, if your consolidation handlers or `OnData` event handler appends data to a `RollingWindow` and you use that `RollingWindow` in your Scheduled Event, when the Scheduled Event executes, the `RollingWindow` won't contain the most recent data.

Live Trading Considerations

In live trading, Scheduled Events execute in a parallel thread based on a real-time clock. If you set a Scheduled Event to fire at 10:00 AM, it executes at exactly 10:00 AM. In backtesting, Scheduled Events are part of the main algorithm manager loop, so they may not execute exactly when you set them. For example, if your algorithm subscribes to minute resolution US Equity data with regular trading hours and you set a Scheduled Event to occur at 2:00 AM, your Scheduled Event will execute at 9:31 AM when the next bar is fed into your algorithm.

The difference between live trading and backtesting is important to note because it can affect your algorithm's behavior. There are two common scenarios to consider.

Execution Timing and Backtest Timeouts

Take the following scenario:

- You set Scheduled Events for 2:00 AM, 3:00 AM, and 4:00 AM each day.
- Each Scheduled Event takes eight minutes to execute.
- Your algorithm only subscribes to US Equity securities without extended market hours (9:30 AM - 4:00 PM).

In this scenario, the Scheduled Events each fire at the correct time and execute without error in live trading. In backtesting, all of the Scheduled Events execute at 9:31 AM when your algorithm receives the first bar of the trading day. Since all the Scheduled Events take eight minutes to execute, the algorithm tries to execute all the Scheduled Events but reaches the 10-minute timeout and the backtest stops execution.

Live Data Delays

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them

milliseconds after the top of each minute. Take the following scenario:

- You subscribe to minute resolution data
- You set a Scheduled Event for 10:00 AM
- The Scheduled Event checks the current asset price

In live trading, the Scheduled Event executes at exactly 10:00 AM but your algorithm may receive the 9:59-10:00 AM bar at 10:00:00.01 AM. Therefore, when you check the price in the Scheduled Event, the price from the 9:58-9:59 AM bar is the latest price. In backtesting, the Scheduled Event gets the price from the 9:59-10:00 AM bar since your algorithm receives the bar at perfect timing.

Examples

PY

```
# Schedule an event to fire at a specific date/time
self.Schedule.On(self.DateRules.On(2013, 10, 7),
                 self.TimeRules.At(13, 0),
                 lambda: self.Log(f"SpecificTime: Fired at : {self.Time}"))

# Schedule an event to fire every trading day for a security the
# The time rule here tells it to fire at 13:00:00 UTC
self.Schedule.On(self.DateRules.EveryDay("SPY"),
                 self.TimeRules.At(13, 0, 0, TimeZones.Utc),
                 lambda: self.Log(f"EveryDay.SPY SpecificTime: Fired at: {self.Time}"))

# Schedule an event to fire every trading day for a security the
# The time rule here tells it to fire 10 minutes after SPY's market open
self.Schedule.On(self.DateRules.EveryDay("SPY"),
                 self.TimeRules.AfterMarketOpen("SPY", 10),
                 lambda: self.Log(f"EveryDay.SPY 10 min after open: Fired at: {self.Time}"))

# Schedule an event to fire every trading day for a security the
# The time rule here tells it to fire 10 minutes before SPY's market close
self.Schedule.On(self.DateRules.EveryDay("SPY"),
                 self.TimeRules.BeforeMarketClose("SPY", 10),
                 lambda: self.Log(f"EveryDay.SPY 10 min before close: Fired at: {self.Time}"))

# Schedule an event to fire on certain days of the week
self.Schedule.On(self.DateRules.Every(DayOfWeek.Monday, DayOfWeek.Friday),
                 self.TimeRules.At(12, 0),
                 lambda: self.Log(f"Mon/Fri at 12pm: Fired at: {self.Time}"))

# Schedule an event to fire once today at when this method is called (now)
self.Schedule.On(self.DateRules.Today,
                 self.TimeRules.Now,
                 lambda: self.Log(f"Now: Fired at: {self.Time}"))

# Schedule an event to fire once tomorrow at midnight
self.Schedule.On(self.DateRules.Tomorrow,
                 self.TimeRules.Midnight,
                 lambda: self.Log(f"Tomorrow at midnight: Fired at: {self.Time}"))

# Schedule an event to fire once today at noon
self.Schedule.On(self.DateRules.Today,
                 self.TimeRules.Noon,
                 lambda: self.Log(f"Today at noon: Fired at: {self.Time}"))

# the scheduling methods return the ScheduledEvent object which can be used
# for other things here I set the event up to check the portfolio value every
# 10 minutes, and liquidate if we have too many losses
self.Schedule.On(self.DateRules.EveryDay(),
                 self.TimeRules.Every(timedelta(minutes=10)),
                 self.LiquidateUnrealizedLosses)

# Schedule an event to fire at the beginning of the month, the symbol is optional.
# if specified, it will fire the first trading day for that symbol of the month,
# if not specified it will fire on the first day of the month
self.Schedule.On(self.DateRules.MonthStart("SPY"),
                 self.TimeRules.AfterMarketOpen("SPY"),
                 self.RebalancingCode)

# Schedule an event to fire at the end of the month, the symbol is optional.
```

```
    # if specified, it will fire the last trading day for that symbol of the month,
    # if not specified it will fire on the first day of the month
    self.Schedule.On(self.DateRules.MonthEnd("SPY"),
                     self.TimeRules.BeforeMarketClose("SPY"),
                     self.RebalancingCode)

    # Schedule an event to fire at the beginning of the week, the symbol is optional.
    # if specified, it will fire the first trading day for that symbol of the week,
    # if not specified it will fire on the first day of the week
    self.Schedule.On(self.DateRules.WeekStart("SPY"),
                     self.TimeRules.AfterMarketOpen("SPY", 5),
                     self.RebalancingCode)

    # Schedule an event to fire at the end of the week, the symbol is optional.
    # if specified, it will fire the last trading day for that symbol of the week,
    # if not specified it will fire on the first day of the week
    self.Schedule.On(self.DateRules.WeekEnd("SPY"),
                     self.TimeRules.BeforeMarketClose("SPY", 5),
                     self.RebalancingCode)

    # The following methods are not defined in Initialize:
    def LiquidateUnrealizedLosses(self) -> None:
        ''' if we have over 1000 dollars in unrealized losses, liquidate'''
        if self.Portfolio.TotalUnrealizedProfit < -1000:
            self.Log(f"Liquidated due to unrealized losses at: {self.Time}")
            self.Liquidate()

    def RebalancingCode(self) -> None:
        ''' Good spot for rebalancing code?'''
        pass
```

Abandoned Baby

Introduction

Create a new Abandoned Baby candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using AbandonedBaby Indicator

To create an automatic indicators for `AbandonedBaby` , call the `AbandonedBaby` helper method from the `QCAlgorithm` class. The `AbandonedBaby` method creates a `AbandonedBaby` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AbandonedBabyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.abandonedbaby = self.AbandonedBaby(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.abandonedbaby.IsReady:
            # The current value of self.abandonedbaby is represented by self.abandonedbaby.Current.Value
            self.Plot("AbandonedBaby", "abandonedbaby", self.abandonedbaby.Current.Value)
```

The following reference table describes the `AbandonedBaby` method:

INDICATORS

AbandonedBaby() 1/1

```
AbandonedBaby QuantConnect.Algorithm.CandlestickPatterns.AbandonedBaby (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `AbandonedBaby` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`AbandonedBaby` - The new `AbandonedBaby` indicator object.

Definition at line 161 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `AbandonedBaby` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class AbandonedBabyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.abandonedbaby = AbandonedBaby()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.abandonedbaby.Update(bar)

        if self.abandonedbaby.IsReady:
            # The current value of self.abandonedbaby is represented by self.abandonedbaby.Current.Value
            self.Plot("AbandonedBaby", "abandonedbaby", self.abandonedbaby.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class AbandonedBabyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.abandonedbaby = AbandonedBaby()
        self.RegisterIndicator(self.symbol, self.abandonedbaby, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.abandonedbaby.IsReady:
            # The current value of self.abandonedbaby is represented by self.abandonedbaby.Current.Value
            self.Plot("AbandonedBaby", "abandonedbaby", self.abandonedbaby.Current.Value)
```

The following reference table describes the `AbandonedBaby` constructor:

INDICATORS

AbandonedBaby() 1/3

```
AbandonedBaby QuantConnect.Indicators.CandlestickPatterns.AbandonedBaby (
string name,
*decimal penetration
)
```

Initializes a new instance of the `AbandonedBaby` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.
`*decimal`	penetration	*(Optional)* Percentage of penetration of a candle within another candle. Default: 0.3m.

Return

`AbandonedBaby` - The new `AbandonedBaby` indicator object.

Definition at line 57 of file Indicators/CandlestickPatterns/AbandonedBaby.cs.

INDICATORS

AbandonedBaby() 2/3

```
AbandonedBaby QuantConnect.Indicators.CandlestickPatterns.AbandonedBaby (
decimal penetration
)
```

Initializes a new instance of the `AbandonedBaby` class.

Show Details

Parameters		
`decimal`	penetration	Percentage of penetration of a candle within another candle.

Return

`AbandonedBaby` - The new `AbandonedBaby` indicator object.

Definition at line 72 of file Indicators/CandlestickPatterns/AbandonedBaby.cs.

INDICATORS

AbandonedBaby() 3/3

```
AbandonedBaby QuantConnect.Indicators.CandlestickPatterns.AbandonedBaby (
)
```

Initializes a new instance of the `AbandonedBaby` class.

Show Details

This method requires no argument input.

Return

`AbandonedBaby` - The new `AbandonedBaby` indicator object.

Definition at line 80 of file Indicators/CandlestickPatterns/AbandonedBaby.cs.

Advance Block

Introduction

Create a new Advance Block candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using AdvanceBlock Indicator

To create an automatic indicators for `AdvanceBlock` , call the `AdvanceBlock` helper method from the `QCAlgorithm` class. The `AdvanceBlock` method creates a `AdvanceBlock` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AdvanceBlockAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.advanceblock = self.AdvanceBlock(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.advanceblock.IsReady:
            # The current value of self.advanceblock is represented by self.advanceblock.Current.Value
            self.Plot("AdvanceBlock", "advanceblock", self.advanceblock.Current.Value)
```

The following reference table describes the `AdvanceBlock` method:

INDICATORS

AdvanceBlock() 1/1

```
AdvanceBlock QuantConnect.Algorithm.CandlestickPatterns.AdvanceBlock (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `AdvanceBlock` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`AdvanceBlock` - The new `AdvanceBlock` indicator object.

Definition at line 177 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

You can manually create a `AdvanceBlock` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class AdvanceBlockAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.advanceblock = AdvanceBlock()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.advanceblock.Update(bar)

        if self.advanceblock.IsReady:
            # The current value of self.advanceblock is represented by self.advanceblock.Current.Value
            self.Plot("AdvanceBlock", "advanceblock", self.advanceblock.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class AdvanceBlockAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.advanceblock = AdvanceBlock()
        self.RegisterIndicator(self.symbol, self.advanceblock, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.advanceblock.IsReady:
            # The current value of self.advanceblock is represented by self.advanceblock.Current.Value
            self.Plot("AdvanceBlock", "advanceblock", self.advanceblock.Current.Value)
```

The following reference table describes the `AdvanceBlock` constructor:

INDICATORS

AdvanceBlock() 1/2

```
AdvanceBlock QuantConnect.Indicators.CandlestickPatterns.AdvanceBlock (
string name
)
```

Initializes a new instance of the `AdvanceBloc` class using the specified name.

Show Details

Parameters		
string	name	The name of this indicator.

Return

`AdvanceBlock` - The new `AdvanceBlock` indicator object.

Definition at line 55 of file Indicators/CandlestickPatterns/AdvanceBlock.cs.

INDICATORS

AdvanceBlock() 2/2

```
AdvanceBlock QuantConnect.Indicators.CandlestickPatterns.AdvanceBlock (

)
```

Initializes a new instance of the `AdvanceBloc` class.

Show Details

This method requires no argument input.

Belt Hold

Introduction

Create a new Belt-hold candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using BeltHold Indicator

To create an automatic indicators for `BeltHold` , call the `BeltHold` helper method from the `QCAlgorithm` class. The `BeltHold` method creates a `BeltHold` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class BeltHoldAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.belthold = self.BeltHold(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.belthold.IsReady:
            # The current value of self.belthold is represented by self.belthold.Current.Value
            self.Plot("BeltHold", "belthold", self.belthold.Current.Value)
```

The following reference table describes the `BeltHold` method:

INDICATORS

BeltHold() 1/1

```
BeltHold QuantConnect.Algorithm.CandlestickPatterns.BeltHold (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `BeltHold` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`BeltHold` - The new `BeltHold` indicator object.

Definition at line 193 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Concealed Baby Swallow

Introduction

Create a new Concealed Baby Swallow candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ConcealedBabySwallow Indicator

To create an automatic indicators for `ConcealedBabySwallow` , call the `ConcealedBabySwallow` helper method from the `QCAlgorithm` class. The `ConcealedBabySwallow` method creates a `ConcealedBabySwallow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ConcealedBabySwallowAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.concealedbabyswallow = self.ConcealedBabySwallow(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.concealedbabyswallow.IsReady:
            # The current value of self.concealedbabyswallow is represented by
self.concealedbabyswallow.Current.Value
            self.Plot("ConcealedBabySwallow", "concealedbabyswallow",
self.concealedbabyswallow.Current.Value)
```

The following reference table describes the `ConcealedBabySwallow` method:

INDICATORS

ConcealedBabySwallow() 1/1

```
ConcealedBabySwallow QuantConnect.Algorithm.CandlestickPatterns.ConcealedBabySwallow (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `ConcealedBabySwallow` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`ConcealedBabySwallow` - The new `ConcealedBabySwallow` indicator object.

Definition at line 241 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ConcealedBabySwallow` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class ConcealedBabySwallowAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.concealedbabyswallow = ConcealedBabySwallow()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.concealedbabyswallow.Update(bar)

        if self.concealedbabyswallow.IsReady:
            # The current value of self.concealedbabyswallow is represented by
self.concealedbabyswallow.Current.Value
            self.Plot("ConcealedBabySwallow", "concealedbabyswallow",
self.concealedbabyswallow.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class ConcealedBabySwallowAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.concealedbabyswallow = ConcealedBabySwallow()
        self.RegisterIndicator(self.symbol, self.concealedbabyswallow, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.concealedbabyswallow.IsReady:
            # The current value of self.concealedbabyswallow is represented by
self.concealedbabyswallow.Current.Value
            self.Plot("ConcealedBabySwallow", "concealedbabyswallow",
self.concealedbabyswallow.Current.Value)
```

The following reference table describes the `ConcealedBabySwallow` constructor:

INDICATORS

ConcealedBabySwallow() 1/2

```
ConcealedBabySwallow QuantConnect.Indicators.CandlestickPatterns.ConcealedBabySwallow (
string name
)
```

Initializes a new instance of the `ConcealedBabySwallo` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`ConcealedBabySwallow` - The new `ConcealedBabySwallow` indicator object.

Definition at line 45 of file Indicators/CandlestickPatterns/ConcealedBabySwallow.cs.

INDICATORS

ConcealedBabySwallow() 2/2

```
ConcealedBabySwallow QuantConnect.Indicators.CandlestickPatterns.ConcealedBabySwallow (

Counterattack

Introduction

Create a new Counterattack candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Counterattack Indicator

To create an automatic indicators for `Counterattack` , call the `Counterattack` helper method from the `QCAlgorithm` class. The `Counterattack` method creates a `Counterattack` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class CounterattackAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.counterattack = self.Counterattack(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.counterattack.IsReady:
            # The current value of self.counterattack is represented by self.counterattack.Current.Value
            self.Plot("Counterattack", "counterattack", self.counterattack.Current.Value)
```

The following reference table describes the `Counterattack` method:

INDICATORS

Counterattack() 1/1

```
Counterattack QuantConnect.Algorithm.CandlestickPatterns.Counterattack (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Counterattack` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Counterattack` - The new `Counterattack` indicator object.

Definition at line 257 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dragonflydoji = DragonflyDoji()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.dragonflydoji.Update(bar)

        if self.dragonflydoji.IsReady:
            # The current value of self.dragonflydoji is represented by self.dragonflydoji.Current.Value
            self.Plot("DragonflyDoji", "dragonflydoji", self.dragonflydoji.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
PY
class DragonflyDojiAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dragonflydoji = DragonflyDoji()
        self.RegisterIndicator(self.symbol, self.dragonflydoji, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.dragonflydoji.IsReady:
            # The current value of self.dragonflydoji is represented by self.dragonflydoji.Current.Value
            self.Plot("DragonflyDoji", "dragonflydoji", self.dragonflydoji.Current.Value)
```

The following reference table describes the `DragonflyDoji` constructor:

INDICATORS

DragonflyDoji() 1/2

```
DragonflyDoji QuantConnect.Indicators.CandlestickPatterns.DragonflyDoji (
string name
)
```

Initializes a new instance of the `DragonflyDoj` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`DragonflyDoji` - The new `DragonflyDoji` indicator object.

Engulfing

Introduction

Create a new Engulfing candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Engulfing Indicator

To create an automatic indicators for `Engulfing` , call the `Engulfing` helper method from the `QCAlgorithm` class. The `Engulfing` method creates a `Engulfing` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class EngulfingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.engulfing = self.Engulfing(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.engulfing.IsReady:
            # The current value of self.engulfing is represented by self.engulfing.Current.Value
            self.Plot("Engulfing", "engulfing", self.engulfing.Current.Value)
```

The following reference table describes the `Engulfing` method:

INDICATORS

Engulfing() 1/1

```
Engulfing QuantConnect.Algorithm.CandlestickPatterns.Engulfing (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Engulfing` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Engulfing` - The new `Engulfing` indicator object.

Definition at line 338 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Engulfing` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class EngulfingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.engulfing = Engulfing()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.engulfing.Update(bar)

        if self.engulfing.IsReady:
            # The current value of self.engulfing is represented by self.engulfing.Current.Value
            self.Plot("Engulfing", "engulfing", self.engulfing.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class EngulfingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.engulfing = Engulfing()
        self.RegisterIndicator(self.symbol, self.engulfing, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.engulfing.IsReady:
            # The current value of self.engulfing is represented by self.engulfing.Current.Value
            self.Plot("Engulfing", "engulfing", self.engulfing.Current.Value)
```

The following reference table describes the `Engulfing` constructor:

INDICATORS

Engulfing() 1/2

```
Engulfing QuantConnect.Indicators.CandlestickPatterns.Engulfing (
string name
)
```

Initializes a new instance of the `Engulfin` class using the specified name.

Show Details

Gap Side By Side White

Introduction

Create a new Up/Down-gap side-by-side white lines candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using GapSideBySideWhite Indicator

To create an automatic indicators for `GapSideBySideWhite` , call the `GapSideBySideWhite` helper method from the `QCAlgorithm` class. The `GapSideBySideWhite` method creates a `GapSideBySideWhite` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
class GapSideBySideWhiteAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.gapsidebysidewhite = self.GapSideBySideWhite(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.gapsidebysidewhite.IsReady:
            # The current value of self.gapsidebysidewhite is represented by
self.gapsidebysidewhite.Current.Value
            self.Plot("GapSideBySideWhite", "gapsidebysidewhite", self.gapsidebysidewhite.Current.Value)
```

The following reference table describes the `GapSideBySideWhite` method:

INDICATORS

GapSideBySideWhite() 1/1

```
GapSideBySideWhite QuantConnect.Algorithm.CandlestickPatterns.GapSideBySideWhite (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `GapSideBySideWhite` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`GapSideBySideWhite` - The new `GapSideBySideWhite` indicator object.

Definition at line 388 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `GapSideBySideWhite` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class GapSideBySideWhiteAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.gapsidebysidewhite = GapSideBySideWhite()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.gapsidebysidewhite.Update(bar)

        if self.gapsidebysidewhite.IsReady:
            # The current value of self.gapsidebysidewhite is represented by
self.gapsidebysidewhite.Current.Value
            self.Plot("GapSideBySideWhite", "gapsidebysidewhite", self.gapsidebysidewhite.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class GapSideBySideWhiteAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.gapsidebysidewhite = GapSideBySideWhite()
        self.RegisterIndicator(self.symbol, self.gapsidebysidewhite, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.gapsidebysidewhite.IsReady:
            # The current value of self.gapsidebysidewhite is represented by
self.gapsidebysidewhite.Current.Value
            self.Plot("GapSideBySideWhite", "gapsidebysidewhite", self.gapsidebysidewhite.Current.Value)
```

The following reference table describes the GapSideBySideWhite constructor:

INDICATORS

GapSideBySideWhite() 1/2

```
GapSideBySideWhite QuantConnect.Indicators.CandlestickPatterns.GapSideBySideWhite (
string name
)
```

Initializes a new instance of the GapSideBySideWhit class using the specified name.

You can manually create a `GravestoneDoji` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class GravestoneDojiAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.gravestonedoji = GravestoneDoji()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.gravestonedoji.Update(bar)

        if self.gravestonedoji.IsReady:
            # The current value of self.gravestonedoji is represented by self.gravestonedoji.Current.Value
            self.Plot("GravestoneDoji", "gravestonedoji", self.gravestonedoji.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class GravestoneDojiAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.gravestonedoji = GravestoneDoji()
        self.RegisterIndicator(self.symbol, self.gravestonedoji, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.gravestonedoji.IsReady:
            # The current value of self.gravestonedoji is represented by self.gravestonedoji.Current.Value
            self.Plot("GravestoneDoji", "gravestonedoji", self.gravestonedoji.Current.Value)
```

The following reference table describes the `GravestoneDoji` constructor:

INDICATORS

GravestoneDoji() 1/2

```
GravestoneDoji QuantConnect.Indicators.CandlestickPatterns.GravestoneDoji (
string name
)
```

Initializes a new instance of the `GravestoneDoj` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`GravestoneDoji` - The new `GravestoneDoji` indicator object.

Supported Indicators

Hammer

Introduction

Create a new Hammer candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Hammer Indicator

To create an automatic indicators for `Hammer` , call the `Hammer` helper method from the `QCAlgorithm` class. The `Hammer` method creates a `Hammer` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class HammerAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hammer = self.Hammer(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.hammer.IsReady:
            # The current value of self.hammer is represented by self.hammer.Current.Value
            self.Plot("Hammer", "hammer", self.hammer.Current.Value)
```

The following reference table describes the `Hammer` method:

INDICATORS

Hammer() 1/1

```
Hammer QuantConnect.Algorithm.CandlestickPatterns.Hammer (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Hammer` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Hammer` - The new `Hammer` indicator object.

Definition at line 420 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Hammer` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class HammerAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hammer = Hammer()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.hammer.Update(bar)

        if self.hammer.IsReady:
            # The current value of self.hammer is represented by self.hammer.Current.Value
            self.Plot("Hammer", "hammer", self.hammer.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class HammerAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hammer = Hammer()
        self.RegisterIndicator(self.symbol, self.hammer, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.hammer.IsReady:
            # The current value of self.hammer is represented by self.hammer.Current.Value
            self.Plot("Hammer", "hammer", self.hammer.Current.Value)
```

The following reference table describes the `Hammer` constructor:

INDICATORS

Hammer() 1/2

```
Hammer QuantConnect.Indicators.CandlestickPatterns.Hammer (
string name
)
```

Initializes a new instance of the `Hamme` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`Hammer` - The new `Hammer` indicator object.

Definition at line 50 of file Indicators/CandlestickPatterns/Hammer.cs.

INDICATORS

Hammer() 2/2

```
Hammer QuantConnect.Indicators.CandlestickPatterns.Hammer (

)
```

Initializes a new instance of the `Hamme` class.

Show Details

This method requires no argument input.

Return

`Hammer` - The new `Hammer` indicator object.

Hanging Man

Introduction

Create a new Hanging Man candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HangingMan Indicator

To create an automatic indicators for `HangingMan` , call the `HangingMan` helper method from the `QCAlgorithm` class. The `HangingMan` method creates a `HangingMan` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class HangingManAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hangingman = self.HangingMan(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.hangingman.IsReady:
            # The current value of self.hangingman is represented by self.hangingman.Current.Value
            self.Plot("HangingMan", "hangingman", self.hangingman.Current.Value)
```

The following reference table describes the `HangingMan` method:

INDICATORS

HangingMan() 1/1

```
HangingMan QuantConnect.Algorithm.CandlestickPatterns.HangingMan (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `HangingMan` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`HangingMan` - The new `HangingMan` indicator object.

Definition at line 436 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Harami

Introduction

Create a new Harami candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Harami Indicator

To create an automatic indicators for `Harami` , call the `Harami` helper method from the `QCAlgorithm` class. The `Harami` method creates a `Harami` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class HaramiAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.harami = self.Harami(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.harami.IsReady:
            # The current value of self.harami is represented by self.harami.Current.Value
            self.Plot("Harami", "harami", self.harami.Current.Value)
```

The following reference table describes the `Harami` method:

INDICATORS

Harami() 1/1

```
Harami QuantConnect.Algorithm.CandlestickPatterns.Harami (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Harami` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Harami` - The new `Harami` indicator object.

Definition at line 452 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. Hikkake

Introduction

Create a new Hikkake candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Hikkake Indicator

To create an automatic indicators for `Hikkake` , call the `Hikkake` helper method from the `QCAlgorithm` class. The `Hikkake` method creates a `Hikkake` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class HikkakeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hikkake = self.Hikkake(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.hikkake.IsReady:
            # The current value of self.hikkake is represented by self.hikkake.Current.Value
            self.Plot("Hikkake", "hikkake", self.hikkake.Current.Value)
```

The following reference table describes the `Hikkake` method:

INDICATORS

Hikkake() 1/1

```
Hikkake QuantConnect.Algorithm.CandlestickPatterns.Hikkake (
 Symbol symbol,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
 )
```

Creates a new `Hikkake` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Hikkake` - The new `Hikkake` indicator object.

Definition at line 500 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Hikkake` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class HikkakeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hikkake = Hikkake()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.hikkake.Update(bar)

        if self.hikkake.IsReady:
            # The current value of self.hikkake is represented by self.hikkake.Current.Value
            self.Plot("Hikkake", "hikkake", self.hikkake.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class HikkakeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hikkake = Hikkake()
        self.RegisterIndicator(self.symbol, self.hikkake, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.hikkake.IsReady:
            # The current value of self.hikkake is represented by self.hikkake.Current.Value
            self.Plot("Hikkake", "hikkake", self.hikkake.Current.Value)
```

The following reference table describes the `Hikkake` constructor:

INDICATORS

Hikkake() 1/2

```
Hikkake QuantConnect.Indicators.CandlestickPatterns.Hikkake (

        if self.invertedhammer.IsReady:
            # The current value of self.invertedhammer is represented by self.invertedhammer.Current.Value
            self.Plot("InvertedHammer", "invertedhammer", self.invertedhammer.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class InvertedHammerAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.invertedhammer = InvertedHammer()
        self.RegisterIndicator(self.symbol, self.invertedhammer, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.invertedhammer.IsReady:
            # The current value of self.invertedhammer is represented by self.invertedhammer.Current.Value
            self.Plot("InvertedHammer", "invertedhammer", self.invertedhammer.Current.Value)
```

The following reference table describes the `InvertedHammer` constructor:

INDICATORS

InvertedHammer() 1/2

```
InvertedHammer QuantConnect.Indicators.CandlestickPatterns.InvertedHammer (
string name
)
```

Initializes a new instance of the `InvertedHamme` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`InvertedHammer` - The new `InvertedHammer` indicator object.

Definition at line 48 of file Indicators/CandlestickPatterns/InvertedHammer.cs.

INDICATORS

InvertedHammer() 2/2

```
InvertedHammer QuantConnect.Indicators.CandlestickPatterns.InvertedHammer (

)
```

Initializes a new instance of the `InvertedHamme` class.

Show Details

This method requires no argument input.

Return

`InvertedHammer` - The new `InvertedHammer` indicator object.

Definition at line 60 of file Indicators/CandlestickPatterns/InvertedHammer.cs.

Supported Indicators

Kicking

Introduction

Create a new Kicking candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Kicking Indicator

To create an automatic indicators for `Kicking` , call the `Kicking` helper method from the `QCAlgorithm` class. The `Kicking` method creates a `Kicking` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class KickingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kicking = self.Kicking(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.kicking.IsReady:
            # The current value of self.kicking is represented by self.kicking.Current.Value
            self.Plot("Kicking", "kicking", self.kicking.Current.Value)
```

The following reference table describes the `Kicking` method:

INDICATORS

Kicking() 1/1

```
Kicking QuantConnect.Algorithm.CandlestickPatterns.Kicking (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Kicking` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Kicking` - The new `Kicking` indicator object.

Definition at line 596 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Kicking` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class KickingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kicking = Kicking()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.kicking.Update(bar)

        if self.kicking.IsReady:
            # The current value of self.kicking is represented by self.kicking.Current.Value
            self.Plot("Kicking", "kicking", self.kicking.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class KickingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kicking = Kicking()
        self.RegisterIndicator(self.symbol, self.kicking, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.kicking.IsReady:
            # The current value of self.kicking is represented by self.kicking.Current.Value
            self.Plot("Kicking", "kicking", self.kicking.Current.Value)
```

The following reference table describes the `Kicking` constructor:

INDICATORS

Kicking() 1/2

```
Kicking QuantConnect.Indicators.CandlestickPatterns.Kicking (
string name
)
```

Initializes a new instance of the `Kickin` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`Kicking` - The new `Kicking` indicator object.

Definition at line 45 of file Indicators/CandlestickPatterns/Kicking.cs.

INDICATORS

Kicking() 2/2

```
Kicking QuantConnect.Indicators.CandlestickPatterns.Kicking (

)
```

Initializes a new instance of the `Kickin` class.

Show Details

This method requires no argument input.

Return

`Kicking` - The new `Kicking` indicator object.

Definition at line 55 of file Indicators/CandlestickPatterns/Kicking.cs.

Kicking By Length

Introduction

Create a new Kicking (bull/bear determined by the longer marubozu) candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using KickingByLength Indicator

To create an automatic indicators for `KickingByLength` , call the `KickingByLength` helper method from the `QCAlgorithm` class. The `KickingByLength` method creates a `KickingByLength` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class KickingByLengthAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kickingbylength = self.KickingByLength(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.kickingbylength.IsReady:
            # The current value of self.kickingbylength is represented by
self.kickingbylength.Current.Value
            self.Plot("KickingByLength", "kickingbylength", self.kickingbylength.Current.Value)
```

The following reference table describes the `KickingByLength` method:

INDICATORS

KickingByLength() 1/1

```
KickingByLength QuantConnect.Algorithm.CandlestickPatterns.KickingByLength (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `KickingByLength` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`KickingByLength` - The new `KickingByLength` indicator object.

Definition at line 612 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Long Line Candle

Introduction

Create a new Long Line Candle candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using LongLineCandle Indicator

To create an automatic indicators for `LongLineCandle` , call the `LongLineCandle` helper method from the `QCAlgorithm` class. The `LongLineCandle` method creates a `LongLineCandle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class LongLineCandleAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.longlinecandle = self.LongLineCandle(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.longlinecandle.IsReady:
            # The current value of self.longlinecandle is represented by self.longlinecandle.Current.Value
            self.Plot("LongLineCandle", "longlinecandle", self.longlinecandle.Current.Value)
```

The following reference table describes the `LongLineCandle` method:

INDICATORS

LongLineCandle() 1/1

```
LongLineCandle QuantConnect.Algorithm.CandlestickPatterns.LongLineCandle (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `LongLineCandle` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`LongLineCandle` - The new `LongLineCandle` indicator object.

Definition at line 660 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Marubozu

Introduction

Create a new Marubozu candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Marubozu Indicator

To create an automatic indicators for `Marubozu` , call the `Marubozu` helper method from the `QCAlgorithm` class. The `Marubozu` method creates a `Marubozu` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class MarubozuAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.marubozu = self.Marubozu(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.marubozu.IsReady:
            # The current value of self.marubozu is represented by self.marubozu.Current.Value
            self.Plot("Marubozu", "marubozu", self.marubozu.Current.Value)
```

The following reference table describes the `Marubozu` method:

INDICATORS

Marubozu() 1/1

```
Marubozu QuantConnect.Algorithm.CandlestickPatterns.Marubozu (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Marubozu` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Marubozu` - The new `Marubozu` indicator object.

Definition at line 676 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Marubozu` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class MarubozuAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.marubozu = Marubozu()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.marubozu.Update(bar)

        if self.marubozu.IsReady:
            # The current value of self.marubozu is represented by self.marubozu.Current.Value
            self.Plot("Marubozu", "marubozu", self.marubozu.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class MarubozuAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.marubozu = Marubozu()
        self.RegisterIndicator(self.symbol, self.marubozu, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.marubozu.IsReady:
            # The current value of self.marubozu is represented by self.marubozu.Current.Value
            self.Plot("Marubozu", "marubozu", self.marubozu.Current.Value)
```

The following reference table describes the `Marubozu` constructor:

INDICATORS

Marubozu() 1/2

```
Marubozu QuantConnect.Indicators.CandlestickPatterns.Marubozu (
string name
)
```

Initializes a new instance of the `Maruboz` class using the specified name.

Show Details

Parameters		
string	name	The name of this indicator.

Return

`Marubozu` - The new `Marubozu` indicator object.

Definition at line 43 of file Indicators/CandlestickPatterns/Marubozu.cs.

INDICATORS

Marubozu() 2/2

```
Marubozu QuantConnect.Indicators.CandlestickPatterns.Marubozu (

)
```

Initializes a new instance of the `Maruboz` class.

Mat Hold

Introduction

Create a new Mat Hold candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MatHold Indicator

To create an automatic indicators for `MatHold` , call the `MatHold` helper method from the `QCAlgorithm` class. The `MatHold` method creates a `MatHold` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class MatHoldAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mathold = self.MatHold(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.mathold.IsReady:
            # The current value of self.mathold is represented by self.mathold.Current.Value
            self.Plot("MatHold", "mathold", self.mathold.Current.Value)
```

The following reference table describes the `MatHold` method:

INDICATORS

MathHold() 1/1

```
MatHold QuantConnect.Algorithm.CandlestickPatterns.MatHold (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `MatHold` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`MatHold` - The new `MatHold` indicator object.

Definition at line 709 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

On Neck

Introduction

Create a new On-Neck candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using OnNeck Indicator

To create an automatic indicators for `OnNeck` , call the `OnNeck` helper method from the `QCAlgorithm` class. The `OnNeck` method creates a `OnNeck` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class OnNeckAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.onneck = self.OnNeck(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.onneck.IsReady:
            # The current value of self.onneck is represented by self.onneck.Current.Value
            self.Plot("OnNeck", "onneck", self.onneck.Current.Value)
```

The following reference table describes the `OnNeck` method:

INDICATORS

OnNeck() 1/1

```
OnNeck QuantConnect.Algorithm.CandlestickPatterns.OnNeck (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `OnNeck` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`OnNeck` - The new `OnNeck` indicator object.

Definition at line 759 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `OnNeck` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class OnNeckAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.onneck = OnNeck()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.onneck.Update(bar)

        if self.onneck.IsReady:
            # The current value of self.onneck is represented by self.onneck.Current.Value
            self.Plot("OnNeck", "onneck", self.onneck.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class OnNeckAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.onneck = OnNeck()
        self.RegisterIndicator(self.symbol, self.onneck, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.onneck.IsReady:
            # The current value of self.onneck is represented by self.onneck.Current.Value
            self.Plot("OnNeck", "onneck", self.onneck.Current.Value)
```

The following reference table describes the `OnNeck` constructor:

INDICATORS

OnNeck() 1/2

```
OnNeck QuantConnect.Indicators.CandlestickPatterns.OnNeck (
string name
)
```

Initializes a new instance of the `OnNec` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`OnNeck` - The new `OnNeck` indicator object.

Definition at line 45 of file Indicators/CandlestickPatterns/OnNeck.cs.

INDICATORS

OnNeck() 2/2

```
OnNeck QuantConnect.Indicators.CandlestickPatterns.OnNeck (

)
```

Initializes a new instance of the `OnNec` class.

Piercing

Introduction

Create a new Piercing candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Piercing Indicator

To create an automatic indicators for `Piercing` , call the `Piercing` helper method from the `QCAlgorithm` class. The `Piercing` method creates a `Piercing` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class PiercingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.piercing = self.Piercing(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.piercing.IsReady:
            # The current value of self.piercing is represented by self.piercing.Current.Value
            self.Plot("Piercing", "piercing", self.piercing.Current.Value)
```

The following reference table describes the `Piercing` method:

INDICATORS

Piercing() 1/1

```
Piercing QuantConnect.Algorithm.CandlestickPatterns.Piercing (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Piercing` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Piercing` - The new `Piercing` indicator object.

Definition at line 775 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Supported Indicators

Short Line Candle

Introduction

Create a new Short Line Candle candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ShortLineCandle Indicator

To create an automatic indicators for `ShortLineCandle` , call the `ShortLineCandle` helper method from the `QCAlgorithm` class. The `ShortLineCandle` method creates a `ShortLineCandle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ShortLineCandleAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.shortlinecandle = self.ShortLineCandle(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.shortlinecandle.IsReady:
            # The current value of self.shortlinecandle is represented by
self.shortlinecandle.Current.Value
            self.Plot("ShortLineCandle", "shortlinecandle", self.shortlinecandle.Current.Value)
```

The following reference table describes the `ShortLineCandle` method:

INDICATORS

ShortLineCandle() 1/1

```
ShortLineCandle QuantConnect.Algorithm.CandlestickPatterns.ShortLineCandle (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `ShortLineCandle` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`ShortLineCandle` - The new `ShortLineCandle` indicator object.

Definition at line 855 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ShortLineCandle` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class ShortLineCandleAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.shortlinecandle = ShortLineCandle()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.shortlinecandle.Update(bar)

        if self.shortlinecandle.IsReady:
            # The current value of self.shortlinecandle is represented by
self.shortlinecandle.Current.Value
            self.Plot("ShortLineCandle", "shortlinecandle", self.shortlinecandle.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class ShortLineCandleAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.shortlinecandle = ShortLineCandle()
        self.RegisterIndicator(self.symbol, self.shortlinecandle, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.shortlinecandle.IsReady:
            # The current value of self.shortlinecandle is represented by
self.shortlinecandle.Current.Value
            self.Plot("ShortLineCandle", "shortlinecandle", self.shortlinecandle.Current.Value)
```

The following reference table describes the `ShortLineCandle` constructor:

INDICATORS

ShortLineCandle() 1/2

```
ShortLineCandle QuantConnect.Indicators.CandlestickPatterns.ShortLineCandle (
string name
)
```

Initializes a new instance of the `ShortLineCandl` class using the specified name.

Show Details

Parameters		
string	name	The name of this indicator.

Return

`ShortLineCandle` - The new `ShortLineCandle` indicator object.

Definition at line 44 of file Indicators/CandlestickPatterns/ShortLineCandle.cs.

INDICATORS

ShortLineCandle() 2/2

```
ShortLineCandle QuantConnect.Indicators.CandlestickPatterns.ShortLineCandle (
)
```

Initializes a new instance of the `ShortLineCandl` class.

Show Details

This method requires no argument input.

Return

`ShortLineCandle` - The new `ShortLineCandle` indicator object.

Definition at line 54 of file Indicators/CandlestickPatterns/ShortLineCandle.cs.

Spinning Top

Introduction

Create a new Spinning Top candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using SpinningTop Indicator

To create an automatic indicators for `SpinningTop` , call the `SpinningTop` helper method from the `QCAlgorithm` class. The `SpinningTop` method creates a `SpinningTop` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class SpinningTopAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.spinningtop = self.SpinningTop(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.spinningtop.IsReady:
            # The current value of self.spinningtop is represented by self.spinningtop.Current.Value
            self.Plot("SpinningTop", "spinningtop", self.spinningtop.Current.Value)
```

The following reference table describes the `SpinningTop` method:

INDICATORS

SpinningTop() 1/1

```
SpinningTop QuantConnect.Algorithm.CandlestickPatterns.SpinningTop (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `SpinningTop` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`SpinningTop` - The new `SpinningTop` indicator object.

Definition at line 871 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

```
class SpinningTopAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.spinningtop = SpinningTop()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.spinningtop.Update(bar)

        if self.spinningtop.IsReady:
            # The current value of self.spinningtop is represented by self.spinningtop.Current.Value
            self.Plot("SpinningTop", "spinningtop", self.spinningtop.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class SpinningTopAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.spinningtop = SpinningTop()
        self.RegisterIndicator(self.symbol, self.spinningtop, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.spinningtop.IsReady:
            # The current value of self.spinningtop is represented by self.spinningtop.Current.Value
            self.Plot("SpinningTop", "spinningtop", self.spinningtop.Current.Value)
```

The following reference table describes the SpinningTop constructor:

INDICATORS

SpinningTop() 1/2

```
SpinningTop QuantConnect.Indicators.CandlestickPatterns.SpinningTop (
string name
)
```

Initializes a new instance of the SpinningTo class using the specified name.

Show Details

Parameters		
string	name	The name of this indicator.

Return

SpinningTop - The new SpinningTop indicator object.

Definition at line 41 of file Indicators/CandlestickPatterns/SpinningTop.cs.

INDICATORS

SpinningTop() 2/2

```
SpinningTop QuantConnect.Indicators.CandlestickPatterns.SpinningTop (
)
```

Initializes a new instance of the `SpinningTo` class.

Show Details

This method requires no argument input.

Stalled Pattern

Introduction

Create a new Stalled Pattern candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using StalledPattern Indicator

To create an automatic indicators for `StalledPattern` , call the `StalledPattern` helper method from the `QCAlgorithm` class. The `StalledPattern` method creates a `StalledPattern` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class StalledPatternAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.stalledpattern = self.StalledPattern(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.stalledpattern.IsReady:
            # The current value of self.stalledpattern is represented by self.stalledpattern.Current.Value
            self.Plot("StalledPattern", "stalledpattern", self.stalledpattern.Current.Value)
```

The following reference table describes the `StalledPattern` method:

INDICATORS

StalledPattern() 1/1

```
StalledPattern QuantConnect.Algorithm.CandlestickPatterns.StalledPattern (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `StalledPattern` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`StalledPattern` - The new `StalledPattern` indicator object.

Definition at line 887 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Tasuki Gap

Introduction

Create a new Tasuki Gap candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using TasukiGap Indicator

To create an automatic indicators for `TasukiGap` , call the `TasukiGap` helper method from the `QCAlgorithm` class. The `TasukiGap` method creates a `TasukiGap` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class TasukiGapAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tasukigap = self.TasukiGap(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.tasukigap.IsReady:
            # The current value of self.tasukigap is represented by self.tasukigap.Current.Value
            self.Plot("TasukiGap", "tasukigap", self.tasukigap.Current.Value)
```

The following reference table describes the `TasukiGap` method:

INDICATORS

TasukiGap() 1/1

```
TasukiGap QuantConnect.Algorithm.CandlestickPatterns.TasukiGap (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `TasukiGap` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`TasukiGap` - The new `TasukiGap` indicator object.

Definition at line 935 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `TasukiGap` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class TasukiGapAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tasukigap = TasukiGap()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.tasukigap.Update(bar)

        if self.tasukigap.IsReady:
            # The current value of self.tasukigap is represented by self.tasukigap.Current.Value
            self.Plot("TasukiGap", "tasukigap", self.tasukigap.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class TasukiGapAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tasukigap = TasukiGap()
        self.RegisterIndicator(self.symbol, self.tasukigap, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.tasukigap.IsReady:
            # The current value of self.tasukigap is represented by self.tasukigap.Current.Value
            self.Plot("TasukiGap", "tasukigap", self.tasukigap.Current.Value)
```

The following reference table describes the TasukiGap constructor:

INDICATORS

TasukiGap() 1/2

```
TasukiGap QuantConnect.Indicators.CandlestickPatterns.TasukiGap (
string name
)
```

Initializes a new instance of the TasukiGa class using the specified name.

Show Details

Parameters		
string	name	The name of this indicator.

Return

TasukiGap - The new TasukiGap indicator object.

Three Black Crows

Introduction

Create a new Three Black Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeBlackCrows Indicator

To create an automatic indicators for `ThreeBlackCrows` , call the `ThreeBlackCrows` helper method from the `QCAlgorithm` class. The `ThreeBlackCrows` method creates a `ThreeBlackCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ThreeBlackCrowsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.threeblackcrows = self.ThreeBlackCrows(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.threeblackcrows.IsReady:
            # The current value of self.threeblackcrows is represented by
self.threeblackcrows.Current.Value
            self.Plot("ThreeBlackCrows", "threeblackcrows", self.threeblackcrows.Current.Value)
```

The following reference table describes the `ThreeBlackCrows` method:

INDICATORS

ThreeBlackCrows() 1/1

```
ThreeBlackCrows QuantConnect.Algorithm.CandlestickPatterns.ThreeBlackCrows (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `ThreeBlackCrows` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`ThreeBlackCrows` - The new `ThreeBlackCrows` indicator object.

Definition at line 64 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ThreeBlackCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class ThreeBlackCrowsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.threeblackcrows = ThreeBlackCrows()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.threeblackcrows.Update(bar)

        if self.threeblackcrows.IsReady:
            # The current value of self.threeblackcrows is represented by
self.threeblackcrows.Current.Value
            self.Plot("ThreeBlackCrows", "threeblackcrows", self.threeblackcrows.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class ThreeBlackCrowsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.threeblackcrows = ThreeBlackCrows()
        self.RegisterIndicator(self.symbol, self.threeblackcrows, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.threeblackcrows.IsReady:
            # The current value of self.threeblackcrows is represented by
self.threeblackcrows.Current.Value
            self.Plot("ThreeBlackCrows", "threeblackcrows", self.threeblackcrows.Current.Value)
```

The following reference table describes the `ThreeBlackCrows` constructor:

INDICATORS

ThreeBlackCrows() 1/2

```
ThreeBlackCrows QuantConnect.Indicators.CandlestickPatterns.ThreeBlackCrows (
string name
)
```

Initializes a new instance of the `ThreeBlackCrow` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`ThreeBlackCrows` - The new `ThreeBlackCrows` indicator object.

Introduction

Create a new Three Advancing White Soldiers candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeWhiteSoldiers Indicator

To create an automatic indicators for `ThreeWhiteSoldiers` , call the `ThreeWhiteSoldiers` helper method from the `QCAlgorithm` class. The `ThreeWhiteSoldiers` method creates a `ThreeWhiteSoldiers` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
PY
class ThreeWhiteSoldiersAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.threewhitesoldiers = self.ThreeWhiteSoldiers(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.threewhitesoldiers.IsReady:
            # The current value of self.threewhitesoldiers is represented by
self.threewhitesoldiers.Current.Value
            self.Plot("ThreeWhiteSoldiers", "threewhitesoldiers", self.threewhitesoldiers.Current.Value)
```

The following reference table describes the `ThreeWhiteSoldiers` method:

INDICATORS

ThreeWhiteSoldiers() 1/1

```
ThreeWhiteSoldiers QuantConnect.Algorithm.CandlestickPatterns.ThreeWhiteSoldiers (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `ThreeWhiteSoldiers` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`ThreeWhiteSoldiers` - The new `ThreeWhiteSoldiers` indicator object.

Definition at line 144 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ThreeWhiteSoldiers` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class ThreeWhiteSoldiersAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.threewhitesoldiers = ThreeWhiteSoldiers()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.threewhitesoldiers.Update(bar)

        if self.threewhitesoldiers.IsReady:
            # The current value of self.threewhitesoldiers is represented by
self.threewhitesoldiers.Current.Value
            self.Plot("ThreeWhiteSoldiers", "threewhitesoldiers", self.threewhitesoldiers.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class ThreeWhiteSoldiersAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.threewhitesoldiers = ThreeWhiteSoldiers()
        self.RegisterIndicator(self.symbol, self.threewhitesoldiers, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.threewhitesoldiers.IsReady:
            # The current value of self.threewhitesoldiers is represented by
self.threewhitesoldiers.Current.Value
            self.Plot("ThreeWhiteSoldiers", "threewhitesoldiers", self.threewhitesoldiers.Current.Value)
```

The following reference table describes the `ThreeWhiteSoldiers` constructor:

INDICATORS

ThreeWhiteSoldiers() 1/2

```
ThreeWhiteSoldiers QuantConnect.Indicators.CandlestickPatterns.ThreeWhiteSoldiers (
string name
)
```

Initializes a new instance of the `ThreeWhiteSoldier` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`ThreeWhiteSoldiers` - The new `ThreeWhiteSoldiers` indicator object.

Definition at line 54 of file Indicators/CandlestickPatterns/ThreeWhiteSoldiers.cs.

INDICATORS

ThreeWhiteSoldiers() 2/2

```
ThreeWhiteSoldiers QuantConnect.Indicators.CandlestickPatterns.ThreeWhiteSoldiers (
)
```

Initializes a new instance of the `ThreeWhiteSoldier` class.

Show Details

This method requires no argument input.

Return

`ThreeWhiteSoldiers` - The new `ThreeWhiteSoldiers` indicator object.

Definition at line 67 of file Indicators/CandlestickPatterns/ThreeWhiteSoldiers.cs.

Supported Indicators

Thrusting

Introduction

Create a new Thrusting candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Thrusting Indicator

To create an automatic indicators for `Thrusting` , call the `Thrusting` helper method from the `QCAlgorithm` class. The `Thrusting` method creates a `Thrusting` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ThrustingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.thrusting = self.Thrusting(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.thrusting.IsReady:
            # The current value of self.thrusting is represented by self.thrusting.Current.Value
            self.Plot("Thrusting", "thrusting", self.thrusting.Current.Value)
```

The following reference table describes the `Thrusting` method:

INDICATORS

Thrusting() 1/1

```
Thrusting QuantConnect.Algorithm.CandlestickPatterns.Thrusting (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Thrusting` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Thrusting` - The new `Thrusting` indicator object.

Definition at line 951 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Thrusting` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class ThrustingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.thrusting = Thrusting()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.thrusting.Update(bar)

        if self.thrusting.IsReady:
            # The current value of self.thrusting is represented by self.thrusting.Current.Value
            self.Plot("Thrusting", "thrusting", self.thrusting.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class ThrustingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.thrusting = Thrusting()
        self.RegisterIndicator(self.symbol, self.thrusting, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.thrusting.IsReady:
            # The current value of self.thrusting is represented by self.thrusting.Current.Value
            self.Plot("Thrusting", "thrusting", self.thrusting.Current.Value)
```

The following reference table describes the `Thrusting` constructor:

INDICATORS

Thrusting() 1/2

```
Thrusting QuantConnect.Indicators.CandlestickPatterns.Thrusting (
string name
)
```

Initializes a new instance of the `Thrustin` class using the specified name.

Show Details

Parameters		
string	name	The name of this indicator.

Return

`Thrusting` - The new `Thrusting` indicator object.

Definition at line 47 of file Indicators/CandlestickPatterns/Thrusting.cs.

INDICATORS

Thrusting() 2/2

```
Thrusting QuantConnect.Indicators.CandlestickPatterns.Thrusting (

)
```

Initializes a new instance of the `Thrustin` class.

Show Details

This method requires no argument input.

Return

`Thrusting` - The new `Thrusting` indicator object.

Definition at line 57 of file Indicators/CandlestickPatterns/Thrusting.cs.

Tristar

Introduction

Create a new Tristar candlestick pattern indicator to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Tristar Indicator

To create an automatic indicators for `Tristar` , call the `Tristar` helper method from the `QCAlgorithm` class. The `Tristar` method creates a `Tristar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class TristarAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tristar = self.Tristar(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.tristar.IsReady:
            # The current value of self.tristar is represented by self.tristar.Current.Value
            self.Plot("Tristar", "tristar", self.tristar.Current.Value)
```

The following reference table describes the `Tristar` method:

INDICATORS

Tristar() 1/1

```
Tristar QuantConnect.Algorithm.CandlestickPatterns.Tristar (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `Tristar` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`Tristar` - The new `Tristar` indicator object.

Definition at line 967 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Tristar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class TristarAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tristar = Tristar()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.tristar.Update(bar)

        if self.tristar.IsReady:
            # The current value of self.tristar is represented by self.tristar.Current.Value
            self.Plot("Tristar", "tristar", self.tristar.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class TristarAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tristar = Tristar()
        self.RegisterIndicator(self.symbol, self.tristar, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.tristar.IsReady:
            # The current value of self.tristar is represented by self.tristar.Current.Value
            self.Plot("Tristar", "tristar", self.tristar.Current.Value)
```

The following reference table describes the `Tristar` constructor:

INDICATORS

Tristar() 1/2

```
Tristar QuantConnect.Indicators.CandlestickPatterns.Tristar (
string name
)
```

Initializes a new instance of the `Trista` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`Tristar` - The new `Tristar` indicator object.

Definition at line 41 of file Indicators/CandlestickPatterns/Tristar.cs.

INDICATORS

Tristar() 2/2

```
Tristar QuantConnect.Indicators.CandlestickPatterns.Tristar (

)
```

Initializes a new instance of the `Trista` class.

Show Details

Up Down Gap Three Methods

Introduction

Create a new Up/Down Gap Three Methods candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using UpDownGapThreeMethods Indicator

To create an automatic indicators for `UpDownGapThreeMethods` , call the `UpDownGapThreeMethods` helper method from the `QCAlgorithm` class. The `UpDownGapThreeMethods` method creates a `UpDownGapThreeMethods` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class UpDownGapThreeMethodsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.updowngapthreemethods = self.UpDownGapThreeMethods(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.updowngapthreemethods.IsReady:
            # The current value of self.updowngapthreemethods is represented by
self.updowngapthreemethods.Current.Value
            self.Plot("UpDownGapThreeMethods", "updowngapthreemethods",
self.updowngapthreemethods.Current.Value)
```

The following reference table describes the `UpDownGapThreeMethods` method:

INDICATORS

UpDownGapThreeMethods() 1/1

```
UpDownGapThreeMethods QuantConnect.Algorithm.CandlestickPatterns.UpDownGapThreeMethods (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `UpDownGapThreeMethods` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`UpDownGapThreeMethods` - The new `UpDownGapThreeMethods` indicator object.

Definition at line 1015 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `UpDownGapThreeMethods` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class UpDownGapThreeMethodsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.updowngapthreemethods = UpDownGapThreeMethods()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.updowngapthreemethods.Update(bar)

        if self.updowngapthreemethods.IsReady:
            # The current value of self.updowngapthreemethods is represented by
self.updowngapthreemethods.Current.Value
            self.Plot("UpDownGapThreeMethods", "updowngapthreemethods",
self.updowngapthreemethods.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class UpDownGapThreeMethodsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.updowngapthreemethods = UpDownGapThreeMethods()
        self.RegisterIndicator(self.symbol, self.updowngapthreemethods, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.updowngapthreemethods.IsReady:
            # The current value of self.updowngapthreemethods is represented by
self.updowngapthreemethods.Current.Value
            self.Plot("UpDownGapThreeMethods", "updowngapthreemethods",
self.updowngapthreemethods.Current.Value)
```

The following reference table describes the `UpDownGapThreeMethods` constructor:

INDICATORS

UpDownGapThreeMethods() 1/2

```
UpDownGapThreeMethods QuantConnect.Indicators.CandlestickPatterns.UpDownGapThreeMethods (
string name
)
```

Initializes a new instance of the `UpDownGapThreeMethod` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`UpDownGapThreeMethods` - The new `UpDownGapThreeMethods` indicator object.

Definition at line 41 of file Indicators/CandlestickPatterns/UpDownGapThreeMethods.cs.

INDICATORS

UpDownGapThreeMethods() 2/2

```
UpDownGapThreeMethods QuantConnect.Indicators.CandlestickPatterns.UpDownGapThreeMethods (

)
```

Initializes a new instance of the `UpDownGapThreeMethod` class.

Show Details

This method requires no argument input.

Return

`UpDownGapThreeMethods` - The new `UpDownGapThreeMethods` indicator object.

Definition at line 49 of file Indicators/CandlestickPatterns/UpDownGapThreeMethods.cs.

Supported Indicators

Upside Gap Two Crows

Introduction

Create a new Upside Gap Two Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using UpsideGapTwoCrows Indicator

To create an automatic indicators for `UpsideGapTwoCrows` , call the `UpsideGapTwoCrows` helper method from the `QCAlgorithm` class. The `UpsideGapTwoCrows` method creates a `UpsideGapTwoCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class UpsideGapTwoCrowsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.upsidegaptwocrows = self.UpsideGapTwoCrows(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.upsidegaptwocrows.IsReady:
            # The current value of self.upsidegaptwocrows is represented by
self.upsidegaptwocrows.Current.Value
            self.Plot("UpsideGapTwoCrows", "upsidegaptwocrows", self.upsidegaptwocrows.Current.Value)
```

The following reference table describes the `UpsideGapTwoCrows` method:

INDICATORS

UpsideGapTwoCrows() 1/1

```
UpsideGapTwoCrows QuantConnect.Algorithm.CandlestickPatterns.UpsideGapTwoCrows (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new `UpsideGapTwoCrows` pattern indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose pattern we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if null defaults to casting the input value to a TradeBar.

Return

`UpsideGapTwoCrows` - The new `UpsideGapTwoCrows` indicator object.

Definition at line 999 of file Algorithm/CandlestickPatterns.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `UpsideGapTwoCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class UpsideGapTwoCrowsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.upsidegaptwocrows = UpsideGapTwoCrows()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.upsidegaptwocrows.Update(bar)

        if self.upsidegaptwocrows.IsReady:
            # The current value of self.upsidegaptwocrows is represented by
self.upsidegaptwocrows.Current.Value
            self.Plot("UpsideGapTwoCrows", "upsidegaptwocrows", self.upsidegaptwocrows.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
PY
class UpsideGapTwoCrowsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.upsidegaptwocrows = UpsideGapTwoCrows()
        self.RegisterIndicator(self.symbol, self.upsidegaptwocrows, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.upsidegaptwocrows.IsReady:
            # The current value of self.upsidegaptwocrows is represented by
self.upsidegaptwocrows.Current.Value
            self.Plot("UpsideGapTwoCrows", "upsidegaptwocrows", self.upsidegaptwocrows.Current.Value)
```

The following reference table describes the `UpsideGapTwoCrows` constructor:

INDICATORS

UpsideGapTwoCrows() 1/2

```
UpsideGapTwoCrows QuantConnect.Indicators.CandlestickPatterns.UpsideGapTwoCrows (
string name
)
```

Initializes a new instance of the `UpsideGapTwoCrow` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`UpsideGapTwoCrows` - The new `UpsideGapTwoCrows` indicator object.

Supported Indicators

Absolute Price Oscillator

Introduction

This indicator computes the Absolute Price Oscillator (APO) The Absolute Price Oscillator is calculated using the following formula: APO[i] = FastMA[i] - SlowMA[i]

To view the implementation of this indicator, see the LEAN GitHub repository .

Using APO Indicator

To create an automatic indicators for `AbsolutePriceOscillator` , call the `APO` helper method from the `QCAlgorithm` class. The `APO` method creates a `AbsolutePriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AbsolutePriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.apo = self.APO(self.symbol, 10, 2, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.apo.IsReady:
            # The current value of self.apo is represented by self.apo.Current.Value
            self.Plot("AbsolutePriceOscillator", "apo", self.apo.Current.Value)
            # Plot all attributes of self.apo
            self.Plot("AbsolutePriceOscillator", "fast", self.apo.Fast.Current.Value)
            self.Plot("AbsolutePriceOscillator", "slow", self.apo.Slow.Current.Value)
            self.Plot("AbsolutePriceOscillator", "signal", self.apo.Signal.Current.Value)
            self.Plot("AbsolutePriceOscillator", "histogram", self.apo.Histogram.Current.Value)
```

The following reference table describes the `APO` method:

INDICATORS

APO() 1/1

```
AbsolutePriceOscillator QuantConnect.Algorithm.QCAlgorithm.APO (
Symbol symbol,
Int32 fastPeriod,
Int32 slowPeriod,
MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new AbsolutePriceOscillator indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose APO we want.
`Int32`	fastPeriod	The fast moving average period.
`Int32`	slowPeriod	The slow moving average period.
`MovingAverageType`	movingAverageType	The type of moving average to use.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AbsolutePriceOscillator` - The AbsolutePriceOscillator indicator for the requested symbol over the specified period.

Definition at line 205 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `AbsolutePriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class AbsolutePriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.apo = AbsolutePriceOscillator(10, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.apo.Update(bar.EndTime, bar.Close)

        if self.apo.IsReady:
            # The current value of self.apo is represented by self.apo.Current.Value
            self.Plot("AbsolutePriceOscillator", "apo", self.apo.Current.Value)
            # Plot all attributes of self.apo
            self.Plot("AbsolutePriceOscillator", "fast", self.apo.Fast.Current.Value)
            self.Plot("AbsolutePriceOscillator", "slow", self.apo.Slow.Current.Value)
            self.Plot("AbsolutePriceOscillator", "signal", self.apo.Signal.Current.Value)
            self.Plot("AbsolutePriceOscillator", "histogram", self.apo.Histogram.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class AbsolutePriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.apo = AbsolutePriceOscillator(10, 20, MovingAverageType.Simple)
        self.RegisterIndicator(self.symbol, self.apo, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.apo.IsReady:
            # The current value of self.apo is represented by self.apo.Current.Value
            self.Plot("AbsolutePriceOscillator", "apo", self.apo.Current.Value)
            # Plot all attributes of self.apo
            self.Plot("AbsolutePriceOscillator", "fast", self.apo.Fast.Current.Value)
            self.Plot("AbsolutePriceOscillator", "slow", self.apo.Slow.Current.Value)
            self.Plot("AbsolutePriceOscillator", "signal", self.apo.Signal.Current.Value)
            self.Plot("AbsolutePriceOscillator", "histogram", self.apo.Histogram.Current.Value)
```

The following reference table describes the `AbsolutePriceOscillator` constructor:

INDICATORS

AbsolutePriceOscillator() 1/2

```
AbsolutePriceOscillator QuantConnect.Indicators.AbsolutePriceOscillator (
string name,
int fastPeriod,
int slowPeriod,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the `AbsolutePriceOscillato` class using the specified name and parameters.

Show Details

Parameters		
string	name	The name of this indicator.
int	fastPeriod	The fast moving average period.
int	slowPeriod	The slow moving average period.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of moving average to use. Default: MovingAverageType.Simple.

Return

AbsolutePriceOscillator - The new AbsolutePriceOscillator indicator object.

Definition at line 35 of file Indicators/AbsolutePriceOscillator.cs.

INDICATORS

AbsolutePriceOscillator() 2/2

```
AbsolutePriceOscillator QuantConnect.Indicators.AbsolutePriceOscillator (
int fastPeriod,
int slowPeriod,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the AbsolutePriceOscillato class using the specified parameters.

Show Details

Parameters		
int	fastPeriod	The fast moving average period.
int	slowPeriod	The slow moving average period.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of moving average to use. Default: MovingAverageType.Simple.

Supported Indicators

Acceleration Bands

Introduction

The Acceleration Bands created by Price Headley plots upper and lower envelope bands around a moving average.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ABANDS Indicator

To create an automatic indicators for `AccelerationBands` , call the `ABANDS` helper method from the `QCAlgorithm` class. The `ABANDS` method creates a `AccelerationBands` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AccelerationBandsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.abands = self.ABANDS(self.symbol, 10, 4, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.abands.IsReady:
            # The current value of self.abands is represented by self.abands.Current.Value
            self.Plot("AccelerationBands", "abands", self.abands.Current.Value)
            # Plot all attributes of self.abands
            self.Plot("AccelerationBands", "middleband", self.abands.MiddleBand.Current.Value)
            self.Plot("AccelerationBands", "upperband", self.abands.UpperBand.Current.Value)
            self.Plot("AccelerationBands", "lowerband", self.abands.LowerBand.Current.Value)
```

The following reference table describes the `ABANDS` method:

INDICATORS

ABANDS() 1/1

```
AccelerationBands QuantConnect.Algorithm.QCAlgorithm.ABANDS (
Symbol symbol,
Int32 period,
*Decimal width,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new Acceleration Bands indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Acceleration Bands we want.
`Int32`	period	The period of the three moving average (middle, upper and lower band).
`*Decimal`	width	*(Optional)* A coefficient specifying the distance between the middle band and upper or lower bands.
`*MovingAverageType`	movingAverageType	*(Optional)* Type of the moving average. *Options: ['Simple', 'Exponential', 'Wilders', 'LinearWeightedMovingAverage', 'DoubleExponential', 'TripleExponential', 'Triangular', 'T3', 'Kama', 'Hull', 'Alma']*
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AccelerationBands` - The new `AccelerationBands` object.

Definition at line 46 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Accumulation Distribution

Introduction

This indicator computes the Accumulation/Distribution (AD) The Accumulation/Distribution is calculated using the following formula: AD = AD + ((Close - Low) - (High - Close)) / (High - Low) * Volume

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AD Indicator

To create an automatic indicators for `AccumulationDistribution` , call the `AD` helper method from the `QCAlgorithm` class. The `AD` method creates a `AccumulationDistribution` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class AccumulationDistributionAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ad = self.AD(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.ad.IsReady:
            # The current value of self.ad is represented by self.ad.Current.Value
            self.Plot("AccumulationDistribution", "ad", self.ad.Current.Value)
```

The following reference table describes the `AD` method:

INDICATORS

AD() 1/1

```
AccumulationDistribution QuantConnect.Algorithm.QCAlgorithm.AD (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new AccumulationDistribution indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose AD we want.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AccumulationDistribution` - The AccumulationDistribution indicator for the requested symbol over the specified period.

Definition at line 64 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

        self.ad = AccumulationDistribution()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.ad.Update(bar)

        if self.ad.IsReady:
            # The current value of self.ad is represented by self.ad.Current.Value
            self.Plot("AccumulationDistribution", "ad", self.ad.Current.Value)
```

PY

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class AccumulationDistributionAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ad = AccumulationDistribution()
        self.RegisterIndicator(self.symbol, self.ad, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.ad.IsReady:
            # The current value of self.ad is represented by self.ad.Current.Value
            self.Plot("AccumulationDistribution", "ad", self.ad.Current.Value)
```

The following reference table describes the `AccumulationDistribution` constructor:

INDICATORS

AccumulationDistribution() 1/2

```
AccumulationDistribution QuantConnect.Indicators.AccumulationDistribution (

)
```

Initializes a new instance of the `AccumulationDistributio` class using the specified name.

Show Details

This method requires no argument input.

Return

`AccumulationDistribution` - The new `AccumulationDistribution` indicator object.

Definition at line 30 of file Indicators/AccumulationDistribution.cs.

INDICATORS

AccumulationDistribution() 2/2

```
AccumulationDistribution QuantConnect.Indicators.AccumulationDistribution (
string name
)
```

Initializes a new instance of the `AccumulationDistributio` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`AccumulationDistribution` - The new `AccumulationDistribution` indicator object.

Accumulation Distribution Oscillator

Introduction

This indicator computes the Accumulation/Distribution Oscillator (ADOSC) The Accumulation/Distribution Oscillator is calculated using the following formula: ADOSC = EMA(fast,AD) - EMA(slow,AD)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADOSC Indicator

To create an automatic indicators for `AccumulationDistributionOscillator` , call the `ADOSC` helper method from the `QCAlgorithm` class. The `ADOSC` method creates a `AccumulationDistributionOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AccumulationDistributionOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adosc = self.ADOSC(self.symbol, 10, 2)

    def OnData(self, slice: Slice) -> None:
        if self.adosc.IsReady:
            # The current value of self.adosc is represented by self.adosc.Current.Value
            self.Plot("AccumulationDistributionOscillator", "adosc", self.adosc.Current.Value)
```

The following reference table describes the `ADOSC` method:

INDICATORS

ADOSC() 1/1

```
AccumulationDistributionOscillator QuantConnect.Algorithm.QCAlgorithm.ADOSC (
Symbol symbol,
Int32 fastPeriod,
Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new AccumulationDistributionOscillator indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ADOSC we want.
`Int32`	fastPeriod	The fast moving average period.
`Int32`	slowPeriod	The slow moving average period.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AccumulationDistributionOscillator` - The AccumulationDistributionOscillator indicator for the requested symbol over the specified period.

Definition at line 83 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `AccumulationDistributionOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class AccumulationDistributionOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adosc = AccumulationDistributionOscillator(10, 20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.adosc.Update(bar)

        if self.adosc.IsReady:
            # The current value of self.adosc is represented by self.adosc.Current.Value
            self.Plot("AccumulationDistributionOscillator", "adosc", self.adosc.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
PY
class AccumulationDistributionOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adosc = AccumulationDistributionOscillator(10, 20)
        self.RegisterIndicator(self.symbol, self.adosc, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.adosc.IsReady:
            # The current value of self.adosc is represented by self.adosc.Current.Value
            self.Plot("AccumulationDistributionOscillator", "adosc", self.adosc.Current.Value)
```

The following reference table describes the `AccumulationDistributionOscillator` constructor:

INDICATORS

AccumulationDistributionOscillator() 1/2

```
AccumulationDistributionOscillator QuantConnect.Indicators.AccumulationDistributionOscillator (
int fastPeriod,
int slowPeriod
)
```

Initializes a new instance of the `AccumulationDistributionOscillato` class using the specified parameters.

Show Details

Parameters		
int	fastPeriod	The fast moving average period.
int	slowPeriod	The slow moving average period.

Return

`AccumulationDistributionOscillator` - The new `AccumulationDistributionOscillator` indicator object.

Definition at line 38 of file Indicators/AccumulationDistributionOscillator.cs.

INDICATORS

AccumulationDistributionOscillator() 2/2

```
AccumulationDistributionOscillator QuantConnect.Indicators.AccumulationDistributionOscillator (
string name,
int fastPeriod,
int slowPeriod
)
```

Initializes a new instance of the `AccumulationDistributionOscillato` class using the specified parameters.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	fastPeriod	The fast moving average period.
`int`	slowPeriod	The slow moving average period.

Return

`AccumulationDistributionOscillator` - The new `AccumulationDistributionOscillator` indicator object.

Advance Decline Difference

Introduction

The Advance Decline Difference compute the difference between the number of stocks that closed higher and the number of stocks that closed lower than their previous day's closing prices.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADDIFF Indicator

To create an automatic indicators for `AdvanceDeclineDifference` , call the `ADDIFF` helper method from the `QCAlgorithm` class. The `ADDIFF` method creates a `AdvanceDeclineDifference` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class AdvanceDeclineDifferenceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.addiff = self.ADDIFF([self.symbol, Symbol.Create("QQQ", SecurityType.Equity, Market.USA)])

    def OnData(self, slice: Slice) -> None:
        if self.addiff.IsReady:
            # The current value of self.addiff is represented by self.addiff.Current.Value
            self.Plot("AdvanceDeclineDifference", "addiff", self.addiff.Current.Value)
```

The following reference table describes the `ADDIFF` method:

INDICATORS

ADDIFF() 1/1

```
AdvanceDeclineDifference QuantConnect.Algorithm.QCAlgorithm.ADDIFF (
IEnumerable<Symbol> symbols,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Show Details

Parameters		
`IEnumerable<Symbol>`	symbols	/
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* /

Return

`AdvanceDeclineDifference` - The new `AdvanceDeclineDifference` object.

Definition at line 2021 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Arms Index

Introduction

The Arms Index, also called the Short-Term Trading Index (TRIN) is a technical analysis indicator that compares the number of advancing and declining stocks (AD Ratio) to advancing and declining volume (AD volume).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIN Indicator

To create an automatic indicators for `ArmsIndex` , call the `TRIN` helper method from the `QCAlgorithm` class. The `TRIN` method creates a `ArmsIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ArmsIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trin = self.TRIN([self.symbol, Symbol.Create("QQQ", SecurityType.Equity, Market.USA)])

    def OnData(self, slice: Slice) -> None:
        if self.trin.IsReady:
            # The current value of self.trin is represented by self.trin.Current.Value
            self.Plot("ArmsIndex", "trin", self.trin.Current.Value)
            # Plot all attributes of self.trin
            self.Plot("ArmsIndex", "adratio", self.trin.ADRatio.Current.Value)
            self.Plot("ArmsIndex", "advratio", self.trin.ADVRatio.Current.Value)
```

The following reference table describes the `TRIN` method:

INDICATORS

TRIN() 1/2

```
ArmsIndex QuantConnect.Algorithm.QCAlgorithm.TRIN (
IEnumerable<Symbol> symbols,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new Arms Index indicator.

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Func<IBaseData, TradeBar>	selector	*(Optional)* /

Return

ArmsIndex - The new ArmsIndex object.

Definition at line 1945 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TRIN() 2/2

```
ArmsIndex QuantConnect.Algorithm.QCAlgorithm.TRIN (
Symbol> symbols,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new Arms Index indicator.

Show Details

Parameters		
Symbol>	symbols	The symbols whose Arms Index we want.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, TradeBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

ArmsIndex - The Arms Index indicator for the requested symbol over the specified period.

Definition at line 1958 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ArmsIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

```py
class ArmsIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trin = ArmsIndex("")

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.trin.Update(bar)

        if self.trin.IsReady:
            # The current value of self.trin is represented by self.trin.Current.Value
            self.Plot("ArmsIndex", "trin", self.trin.Current.Value)
            # Plot all attributes of self.trin
            self.Plot("ArmsIndex", "adratio", self.trin.ADRatio.Current.Value)
            self.Plot("ArmsIndex", "advratio", self.trin.ADVRatio.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class ArmsIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trin = ArmsIndex("")
        self.RegisterIndicator(self.symbol, self.trin, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.trin.IsReady:
            # The current value of self.trin is represented by self.trin.Current.Value
            self.Plot("ArmsIndex", "trin", self.trin.Current.Value)
            # Plot all attributes of self.trin
            self.Plot("ArmsIndex", "adratio", self.trin.ADRatio.Current.Value)
            self.Plot("ArmsIndex", "advratio", self.trin.ADVRatio.Current.Value)
```

The following reference table describes the `ArmsIndex` constructor:

INDICATORS

ArmsIndex() 1/1

```
ArmsIndex QuantConnect.Indicators.ArmsIndex (
)
```

Initializes a new instance of the `ArmsInde` class.

Show Details

This method requires no argument input.

Return

`ArmsIndex` - The new `ArmsIndex` indicator object.

Arnaud Legoux Moving Average

Introduction

Smooth and high sensitive moving Average. This moving average reduce lag of the information but still being smooth to reduce noises. Is a weighted moving average, which weights have a Normal shape; the parameters Sigma and Offset affect the kurtosis and skewness of the weights respectively. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ALMA Indicator

To create an automatic indicators for `ArnaudLegouxMovingAverage` , call the `ALMA` helper method from the `QCAlgorithm` class. The `ALMA` method creates a `ArnaudLegouxMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ArnaudLegouxMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.alma = self.ALMA(self.symbol, 10, 6, 0.85)

    def OnData(self, slice: Slice) -> None:
        if self.alma.IsReady:
            # The current value of self.alma is represented by self.alma.Current.Value
            self.Plot("ArnaudLegouxMovingAverage", "alma", self.alma.Current.Value)
```

The following reference table describes the `ALMA` method:

INDICATORS

ALMA() 1/1

```
ArnaudLegouxMovingAverage QuantConnect.Algorithm.QCAlgorithm.ALMA (
Symbol symbol,
Int32 period,
*Int32 sigma,
*Decimal offset,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new ArnaudLegouxMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ALMA we want.
`Int32`	period	int - the number of periods to calculate the ALMA.
`*Int32`	sigma	*(Optional)* int - this parameter is responsible for the shape of the curve coefficients. .
`*Decimal`	offset	*(Optional)* decimal - This parameter allows regulating the smoothness and high sensitivity of the Moving Average. The range for this parameter is [0, 1]. .
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`ArnaudLegouxMovingAverage` - The ArnaudLegouxMovingAverage indicator for the requested symbol over the specified period.

Definition at line 185 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ArnaudLegouxMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class ArnaudLegouxMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.alma = ArnaudLegouxMovingAverage(10, 6, 0.85)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.alma.Update(bar.EndTime, bar.Close)

        if self.alma.IsReady:
            # The current value of self.alma is represented by self.alma.Current.Value
            self.Plot("ArnaudLegouxMovingAverage", "alma", self.alma.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class ArnaudLegouxMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.alma = ArnaudLegouxMovingAverage(10, 6, 0.85)
        self.RegisterIndicator(self.symbol, self.alma, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.alma.IsReady:
            # The current value of self.alma is represented by self.alma.Current.Value
            self.Plot("ArnaudLegouxMovingAverage", "alma", self.alma.Current.Value)
```

The following reference table describes the `ArnaudLegouxMovingAverage` constructor:

INDICATORS

ArnaudLegouxMovingAverage() 1/4

```
ArnaudLegouxMovingAverage QuantConnect.Indicators.ArnaudLegouxMovingAverage (
string name,
int period
)
```

Initializes a new instance of the `ArnaudLegouxMovingAverage` class.

Show Details

Parameters		
`string`	name	string - a name for the indicator.
`int`	period	int - the number of periods to calculate the ALMA.

Return

`ArnaudLegouxMovingAverage` - The new `ArnaudLegouxMovingAverage` indicator object.

Definition at line 50 of file Indicators/ArnaudLegouxMovingAverage.cs.

INDICATORS

ArnaudLegouxMovingAverage() 2/4

```
ArnaudLegouxMovingAverage QuantConnect.Indicators.ArnaudLegouxMovingAverage (

Aroon Oscillator

Introduction

The Aroon Oscillator is the difference between AroonUp and AroonDown. The value of this indicator fluctuates between -100 and +100. An upward trend bias is present when the oscillator is positive, and a negative trend bias is present when the oscillator is negative. AroonUp/Down values over 75 identify strong trends in their respective direction.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AROON Indicator

To create an automatic indicators for `AroonOscillator` , call the `AROON` helper method from the `QCAlgorithm` class. The `AROON` method creates a `AroonOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AroonOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.aroon = self.AROON(self.symbol, 10, 20)

    def OnData(self, slice: Slice) -> None:
        if self.aroon.IsReady:
            # The current value of self.aroon is represented by self.aroon.Current.Value
            self.Plot("AroonOscillator", "aroon", self.aroon.Current.Value)
            # Plot all attributes of self.aroon
            self.Plot("AroonOscillator", "aroonup", self.aroon.AroonUp.Current.Value)
            self.Plot("AroonOscillator", "aroondown", self.aroon.AroonDown.Current.Value)
```

The following reference table describes the `AROON` method:

INDICATORS

AROON() 1/2

```
AroonOscillator QuantConnect.Algorithm.QCAlgorithm.AROON (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new AroonOscillator indicator which will compute the AroonUp and AroonDown (as well as the delta).

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Aroon we seek.
`Int32`	period	The look back period for computing number of periods since maximum and minimum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AroonOscillator` - An AroonOscillator configured with the specified periods.

Definition at line 223 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

AROON() 2/2

```
AroonOscillator QuantConnect.Algorithm.QCAlgorithm.AROON (
 Symbol symbol,
 Int32 upPeriod,
 Int32 downPeriod,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new AroonOscillator indicator which will compute the AroonUp and AroonDown (as well as the delta).

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Aroon we seek.
`Int32`	upPeriod	The look back period for computing number of periods since maximum.
`Int32`	downPeriod	The look back period for computing number of periods since minimum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AroonOscillator` - An AroonOscillator configured with the specified periods.

Definition at line 238 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `AroonOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class AroonOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.aroon = AroonOscillator(10, 20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.aroon.Update(bar)

        if self.aroon.IsReady:
            # The current value of self.aroon is represented by self.aroon.Current.Value
            self.Plot("AroonOscillator", "aroon", self.aroon.Current.Value)
            # Plot all attributes of self.aroon
            self.Plot("AroonOscillator", "aroonup", self.aroon.AroonUp.Current.Value)
            self.Plot("AroonOscillator", "aroondown", self.aroon.AroonDown.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class AroonOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.aroon = AroonOscillator(10, 20)
        self.RegisterIndicator(self.symbol, self.aroon, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.aroon.IsReady:
            # The current value of self.aroon is represented by self.aroon.Current.Value
            self.Plot("AroonOscillator", "aroon", self.aroon.Current.Value)
            # Plot all attributes of self.aroon
            self.Plot("AroonOscillator", "aroonup", self.aroon.AroonUp.Current.Value)
            self.Plot("AroonOscillator", "aroondown", self.aroon.AroonDown.Current.Value)
```

The following reference table describes the `AroonOscillator` constructor:

INDICATORS

AroonOscillator() 1/2

```
AroonOscillator QuantConnect.Indicators.AroonOscillator (
int upPeriod,
int downPeriod
)
```

Creates a new AroonOscillator from the specified up/down periods.

Show Details

Parameters		
int	upPeriod	The lookback period to determine the highest high for the AroonDown.
int	downPeriod	The lookback period to determine the lowest low for the AroonUp.

Return

`AroonOscillator` - The new `AroonOscillator` indicator object.

Definition at line 54 of file Indicators/AroonOscillator.cs.

INDICATORS

AroonOscillator() 2/2

```
AroonOscillator QuantConnect.Indicators.AroonOscillator (
string name,
int upPeriod,
int downPeriod
)
```

Creates a new AroonOscillator from the specified up/down periods.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	upPeriod	The lookback period to determine the highest high for the AroonDown.
`int`	downPeriod	The lookback period to determine the lowest low for the AroonUp.

Return

`AroonOscillator` - The new `AroonOscillator` indicator object.

Augen Price Spike

Introduction

The Augen Price Spike indicator is an indicator that measures price changes in terms of standard deviations. In the book, The Volatility Edge in Options Trading, Jeff Augen describes a method for tracking absolute price changes in terms of recent volatility, using the standard deviation. length = x closes = closeArray closes1 = closeArray shifted right by 1 closes2 = closeArray shifted right by 2 closeLog = np.log(np.divide(closes1, closes2)) SDev = np.std(closeLog) m = SDev * closes1[-1] spike = (closes[-1]-closes1[-1])/m return spike Augen Price Spike from TradingView https://www.tradingview.com/script/fC7Pn2X2-Price-Spike-Jeff-Augen/

To view the implementation of this indicator, see the LEAN GitHub repository .

Using APS Indicator

To create an automatic indicators for `AugenPriceSpike` , call the `APS` helper method from the `QCAlgorithm` class. The `APS` method creates a `AugenPriceSpike` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class AugenPriceSpikeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.aps = self.APS(self.symbol, 3)

    def OnData(self, slice: Slice) -> None:
        if self.aps.IsReady:
            # The current value of self.aps is represented by self.aps.Current.Value
            self.Plot("AugenPriceSpike", "aps", self.aps.Current.Value)
```

The following reference table describes the `APS` method:

INDICATORS

APS() 1/1

```
AugenPriceSpike QuantConnect.Algorithm.QCAlgorithm.APS (
Symbol symbol,
*Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates an AugenPriceSpike indicator for the symbol. The indicator will be automatically updated on the given

resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose APS we want.
`*Int32`	period	*(Optional)* The period of the APS.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AugenPriceSpike` - The AugenPriceSpike indicator for the given parameters.

Definition at line 277 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `AugenPriceSpike` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class AugenPriceSpikeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.aps = AugenPriceSpike(3)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.aps.Update(bar.EndTime, bar.Close)

        if self.aps.IsReady:
            # The current value of self.aps is represented by self.aps.Current.Value
            self.Plot("AugenPriceSpike", "aps", self.aps.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class AugenPriceSpikeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.aps = AugenPriceSpike(3)
        self.RegisterIndicator(self.symbol, self.aps, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.aps.IsReady:
            # The current value of self.aps is represented by self.aps.Current.Value
            self.Plot("AugenPriceSpike", "aps", self.aps.Current.Value)
```

The following reference table describes the `AugenPriceSpike` constructor:

INDICATORS

AugenPriceSpike() 1/2

```
AugenPriceSpike QuantConnect.Indicators.AugenPriceSpike (
*int period
)
```

Initializes a new instance of the AugenPriceSpike class using the specified period.

Show Details

Parameters		
*int	period	*(Optional) (Optional)* The period over which to perform to computation. Default: 3.

Return

`AugenPriceSpike` - The new `AugenPriceSpike` indicator object.

Definition at line 49 of file Indicators/AugenPriceSpike.cs.

INDICATORS

AugenPriceSpike() 2/2

```
AugenPriceSpike QuantConnect.Indicators.AugenPriceSpike (
string name,

Auto Regressive Integrated Moving Average

Introduction

An Autoregressive Intergrated Moving Average (ARIMA) is a time series model which can be used to describe a set of data. In particular,with X_t representing the series, the model assumes the data are of form (after differencing times): $X_t = c + \varepsilon_t + \Sigma_i \varphi_i X_{t-i} + \Sigma_i \theta_i \varepsilon_{t-i}$ where the first sum has an upper limit of and the second .

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ARIMA Indicator

To create an automatic indicators for `AutoRegressiveIntegratedMovingAverage` , call the `ARIMA` helper method from the `QCAlgorithm` class. The `ARIMA` method creates a `AutoRegressiveIntegratedMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AutoRegressiveIntegratedMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.arima = self.ARIMA(self.symbol, 1, 1, 1, 20)

    def OnData(self, slice: Slice) -> None:
        if self.arima.IsReady:
            # The current value of self.arima is represented by self.arima.Current.Value
            self.Plot("AutoRegressiveIntegratedMovingAverage", "arima", self.arima.Current.Value)
            # Plot all attributes of self.arima
            self.Plot("AutoRegressiveIntegratedMovingAverage", "arresidualerror",
self.arima.ArResidualError.Current.Value)
            self.Plot("AutoRegressiveIntegratedMovingAverage", "maresidualerror",
self.arima.MaResidualError.Current.Value)
```

The following reference table describes the `ARIMA` method:

INDICATORS

ARIMA() 1/1

```
AutoRegressiveIntegratedMovingAverage QuantConnect.Algorithm.QCAlgorithm.ARIMA (
Symbol symbol,
Int32 arOrder,
Int32 diffOrder,
Int32 maOrder,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new ARIMA indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ARIMA indicator we want.
`Int32`	arOrder	AR order (p) -- defines the number of past values to consider in the AR component of the model.
`Int32`	diffOrder	Difference order (d) -- defines how many times to difference the model before fitting parameters.
`Int32`	maOrder	MA order (q) -- defines the number of past values to consider in the MA component of the model.
`Int32`	period	Size of the rolling series to fit onto.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AutoRegressiveIntegratedMovingAverage` - The ARIMA indicator for the requested symbol over the specified period.

Definition at line 104 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `AutoRegressiveIntegratedMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```
class AutoRegressiveIntegratedMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.arima = AutoRegressiveIntegratedMovingAverage(1, 1, 1, 20, True)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.arima.Update(bar.EndTime, bar.Close)

        if self.arima.IsReady:
            # The current value of self.arima is represented by self.arima.Current.Value
            self.Plot("AutoRegressiveIntegratedMovingAverage", "arima", self.arima.Current.Value)
            # Plot all attributes of self.arima
            self.Plot("AutoRegressiveIntegratedMovingAverage", "arresidualerror",
self.arima.ArResidualError.Current.Value)
            self.Plot("AutoRegressiveIntegratedMovingAverage", "maresidualerror",
self.arima.MaResidualError.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class AutoRegressiveIntegratedMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.arima = AutoRegressiveIntegratedMovingAverage(1, 1, 1, 20, True)
        self.RegisterIndicator(self.symbol, self.arima, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.arima.IsReady:
            # The current value of self.arima is represented by self.arima.Current.Value
            self.Plot("AutoRegressiveIntegratedMovingAverage", "arima", self.arima.Current.Value)
            # Plot all attributes of self.arima
            self.Plot("AutoRegressiveIntegratedMovingAverage", "arresidualerror",
self.arima.ArResidualError.Current.Value)
            self.Plot("AutoRegressiveIntegratedMovingAverage", "maresidualerror",
self.arima.MaResidualError.Current.Value)
```

The following reference table describes the `AutoRegressiveIntegratedMovingAverage` constructor:

INDICATORS

AutoRegressiveIntegratedMovingAverage() 1/2

```
AutoRegressiveIntegratedMovingAverage QuantConnect.Indicators.AutoRegressiveIntegratedMovingAverage (
string name,
int arOrder,
int diffOrder,
int maOrder,
int period,
*bool intercept
)
```

This particular constructor fits the model by means of `TwoStepFit` for a specified name.

Show Details

Parameters		
`string`	name	The name of the indicator.
`int`	arOrder	AR order (p) -- defines the number of past values to consider in the AR component of the model.
`int`	diffOrder	Difference order (d) -- defines how many times to difference the model before fitting parameters.
`int`	maOrder	MA order -- defines the number of past values to consider in the MA component of the model.
`int`	period	Size of the rolling series to fit onto.
`*bool`	intercept	*(Optional) (Optional)* Whether ot not to include the intercept term. Default: true.

Return

`AutoRegressiveIntegratedMovingAverage` - The new `AutoRegressiveIntegratedMovingAverage` indicator object.

Definition at line 105 of file Indicators/AutoRegressiveIntegratedMovingAverage.cs.

INDICATORS

AutoRegressiveIntegratedMovingAverage() 2/2

```
AutoRegressiveIntegratedMovingAverage QuantConnect.Indicators.AutoRegressiveIntegratedMovingAverage (
int arOrder,
int diffOrder,
int maOrder,
int period,
bool intercept
)
```

This particular constructor fits the model by means of `TwoStepFit` using ordinary least squares.

Show Details

Parameters		
`int`	arOrder	AR order (p) -- defines the number of past values to consider in the AR component of the model.
`int`	diffOrder	Difference order (d) -- defines how many times to difference the model before fitting parameters.
`int`	maOrder	MA order (q) -- defines the number of past values to consider in the MA component of the model.
`int`	period	Size of the rolling series to fit onto.
`bool`	intercept	Whether to include an intercept term (c).

Return

`AutoRegressiveIntegratedMovingAverage` - The new `AutoRegressiveIntegratedMovingAverage` indicator object.

Supported Indicators

Average Directional Index

Introduction

This indicator computes Average Directional Index which measures trend strength without regard to trend direction. Firstly, it calculates the Directional Movement and the True Range value, and then the values are accumulated and smoothed using a custom smoothing method proposed by Wilder. For an n period smoothing, 1/n of each period's value is added to the total period. From these accumulated values we are therefore able to derived the 'Positive Directional Index' (+DI) and 'Negative Directional Index' (-DI) which is used to calculate the Average Directional Index. Computation source: https://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:average_directional_index_adx

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADX Indicator

To create an automatic indicators for `AverageDirectionalIndex` , call the `ADX` helper method from the `QCAlgorithm` class. The `ADX` method creates a `AverageDirectionalIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AverageDirectionalIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adx = self.ADX(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.adx.IsReady:
            # The current value of self.adx is represented by self.adx.Current.Value
            self.Plot("AverageDirectionalIndex", "adx", self.adx.Current.Value)
            # Plot all attributes of self.adx
            self.Plot("AverageDirectionalIndex", "positivedirectionalindex",
self.adx.PositiveDirectionalIndex.Current.Value)
            self.Plot("AverageDirectionalIndex", "negativedirectionalindex",
self.adx.NegativeDirectionalIndex.Current.Value)
```

The following reference table describes the `ADX` method:

INDICATORS

ADX() 1/1

```
AverageDirectionalIndex QuantConnect.Algorithm.QCAlgorithm.ADX (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Average Directional Index indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Average Directional Index we seek.
`Int32`	period	The period over which to compute the Average Directional Index.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AverageDirectionalIndex` - The Average Directional Index indicator for the requested symbol.

Definition at line 124 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `AverageDirectionalIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```
class AverageDirectionalIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adx = AverageDirectionalIndex(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.adx.Update(bar)

        if self.adx.IsReady:
            # The current value of self.adx is represented by self.adx.Current.Value
            self.Plot("AverageDirectionalIndex", "adx", self.adx.Current.Value)
            # Plot all attributes of self.adx
            self.Plot("AverageDirectionalIndex", "positivedirectionalindex",
self.adx.PositiveDirectionalIndex.Current.Value)
            self.Plot("AverageDirectionalIndex", "negativedirectionalindex",
self.adx.NegativeDirectionalIndex.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class AverageDirectionalIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adx = AverageDirectionalIndex(20)
        self.RegisterIndicator(self.symbol, self.adx, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.adx.IsReady:
            # The current value of self.adx is represented by self.adx.Current.Value
            self.Plot("AverageDirectionalIndex", "adx", self.adx.Current.Value)
            # Plot all attributes of self.adx
            self.Plot("AverageDirectionalIndex", "positivedirectionalindex",
self.adx.PositiveDirectionalIndex.Current.Value)
            self.Plot("AverageDirectionalIndex", "negativedirectionalindex",
self.adx.NegativeDirectionalIndex.Current.Value)
```

The following reference table describes the `AverageDirectionalIndex` constructor:

INDICATORS

AverageDirectionalIndex() 1/2

```
AverageDirectionalIndex QuantConnect.Indicators.AverageDirectionalIndex (
int period
)
```

Initializes a new instance of the `AverageDirectionalInde` class.

Show Details

Average Directional Movement Index Rating

Introduction

This indicator computes the Average Directional Movement Index Rating (ADXR). The Average Directional Movement Index Rating is calculated with the following formula: ADXR[i] = (ADX[i] + ADX[i - period + 1]) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADXR Indicator

To create an automatic indicators for `AverageDirectionalMovementIndexRating` , call the `ADXR` helper method from the `QCAlgorithm` class. The `ADXR` method creates a `AverageDirectionalMovementIndexRating` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class AverageDirectionalMovementIndexRatingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adxr = self.ADXR(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.adxr.IsReady:
            # The current value of self.adxr is represented by self.adxr.Current.Value
            self.Plot("AverageDirectionalMovementIndexRating", "adxr", self.adxr.Current.Value)
            # Plot all attributes of self.adxr
            self.Plot("AverageDirectionalMovementIndexRating", "adx", self.adxr.ADX.Current.Value)
```

The following reference table describes the `ADXR` method:

INDICATORS

ADXR() 1/1

```
AverageDirectionalMovementIndexRating QuantConnect.Algorithm.QCAlgorithm.ADXR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new AverageDirectionalMovementIndexRating indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ADXR we want.
`Int32`	period	The period over which to compute the ADXR.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AverageDirectionalMovementIndexRating` - The AverageDirectionalMovementIndexRating indicator for the requested symbol over the specified period.

Definition at line 161 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `AverageDirectionalMovementIndexRating` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class AverageDirectionalMovementIndexRatingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adxr = AverageDirectionalMovementIndexRating(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.adxr.Update(bar)

        if self.adxr.IsReady:
            # The current value of self.adxr is represented by self.adxr.Current.Value
            self.Plot("AverageDirectionalMovementIndexRating", "adxr", self.adxr.Current.Value)
            # Plot all attributes of self.adxr
            self.Plot("AverageDirectionalMovementIndexRating", "adx", self.adxr.ADX.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class AverageDirectionalMovementIndexRatingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.adxr = AverageDirectionalMovementIndexRating(20)
        self.RegisterIndicator(self.symbol, self.adxr, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.adxr.IsReady:
            # The current value of self.adxr is represented by self.adxr.Current.Value
            self.Plot("AverageDirectionalMovementIndexRating", "adxr", self.adxr.Current.Value)
            # Plot all attributes of self.adxr
            self.Plot("AverageDirectionalMovementIndexRating", "adx", self.adxr.ADX.Current.Value)
```

The following reference table describes the `AverageDirectionalMovementIndexRating` constructor:

INDICATORS

AverageDirectionalMovementIndexRating() 1/2

```
AverageDirectionalMovementIndexRating QuantConnect.Indicators.AverageDirectionalMovementIndexRating (
string name,
int period
)
```

Initializes a new instance of the `AverageDirectionalMovementIndexRatin` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the ADXR.

Return

`AverageDirectionalMovementIndexRating` - The new `AverageDirectionalMovementIndexRating` indicator object.

Supported Indicators

Average True Range

Introduction

The AverageTrueRange indicator is a measure of volatility introduced by Welles Wilder in his book: New Concepts in Technical Trading Systems. This indicator computes the TrueRange and then smoothes the TrueRange over a given period. TrueRange is defined as the maximum of the following: High - Low ABS(High - PreviousClose) ABS(Low - PreviousClose)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ATR Indicator

To create an automatic indicators for `AverageTrueRange` , call the `ATR` helper method from the `QCAlgorithm` class. The `ATR` method creates a `AverageTrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class AverageTrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.atr = self.ATR(self.symbol, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.atr.IsReady:
            # The current value of self.atr is represented by self.atr.Current.Value
            self.Plot("AverageTrueRange", "atr", self.atr.Current.Value)
            # Plot all attributes of self.atr
            self.Plot("AverageTrueRange", "truerange", self.atr.TrueRange.Current.Value)
```

The following reference table describes the `ATR` method:

INDICATORS

ATR() 1/1

```
AverageTrueRange QuantConnect.Algorithm.QCAlgorithm.ATR (
Symbol symbol,
Int32 period,
*MovingAverageType type,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new AverageTrueRange indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ATR we want.
`Int32`	period	The smoothing period used to smooth the computed TrueRange values.
`*MovingAverageType`	type	*(Optional)* The type of smoothing to use.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AverageTrueRange` - A new AverageTrueRange indicator with the specified smoothing type and period.

Definition at line 258 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

class AverageTrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.atr = AverageTrueRange(20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.atr.Update(bar)

        if self.atr.IsReady:
            # The current value of self.atr is represented by self.atr.Current.Value
            self.Plot("AverageTrueRange", "atr", self.atr.Current.Value)
            # Plot all attributes of self.atr
            self.Plot("AverageTrueRange", "truerange", self.atr.TrueRange.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class AverageTrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.atr = AverageTrueRange(20, MovingAverageType.Simple)
        self.RegisterIndicator(self.symbol, self.atr, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.atr.IsReady:
            # The current value of self.atr is represented by self.atr.Current.Value
            self.Plot("AverageTrueRange", "atr", self.atr.Current.Value)
            # Plot all attributes of self.atr
            self.Plot("AverageTrueRange", "truerange", self.atr.TrueRange.Current.Value)
```

The following reference table describes the `AverageTrueRange` constructor:

INDICATORS

AverageTrueRange() 1/2

```
AverageTrueRange QuantConnect.Indicators.AverageTrueRange (
string name,
int period,
*MovingAverageType movingAverageType
)
```

Creates a new AverageTrueRange indicator using the specified period and moving average type.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The smoothing period used to smooth the true range values.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of smoothing used to smooth the true range values. Default: MovingAverageType.Wilders.

Return

AverageTrueRange - The new AverageTrueRange indicator object.

Awesome Oscillator

Introduction

The Awesome Oscillator Indicator tracks the price midpoint-movement of a security. Specifically, AO = MAfast[(H+L)/2] - MAslow[(H+L)/2] where MAfast and MAslow denote simple moving averages wherein fast has a shorter period. https://www.barchart.com/education/technical-indicators/awesome_oscillator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AO Indicator

To create an automatic indicators for `AwesomeOscillator` , call the `AO` helper method from the `QCAlgorithm` class. The `AO` method creates a `AwesomeOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class AwesomeOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ao = self.AO(self.symbol, 10, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.ao.IsReady:
            # The current value of self.ao is represented by self.ao.Current.Value
            self.Plot("AwesomeOscillator", "ao", self.ao.Current.Value)
            # Plot all attributes of self.ao
            self.Plot("AwesomeOscillator", "slowao", self.ao.SlowAo.Current.Value)
            self.Plot("AwesomeOscillator", "fastao", self.ao.FastAo.Current.Value)
```

The following reference table describes the `AO` method:

INDICATORS

AO() 1/1

```
AwesomeOscillator QuantConnect.Algorithm.QCAlgorithm.AO (
Symbol symbol,
Int32 slowPeriod,
Int32 fastPeriod,
MovingAverageType type,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Awesome Oscillator from the specified periods.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Awesome Oscillator we seek.
`Int32`	slowPeriod	The period of the slow moving average associated with the AO.
`Int32`	fastPeriod	The period of the fast moving average associated with the AO.
`MovingAverageType`	type	The type of moving average used when computing the fast and slow term. Defaults to simple moving average.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AwesomeOscillator` - The new `AwesomeOscillator` object.

Definition at line 143 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `AwesomeOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```py
class AwesomeOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ao = AwesomeOscillator(10, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.ao.Update(bar)

        if self.ao.IsReady:
            # The current value of self.ao is represented by self.ao.Current.Value
            self.Plot("AwesomeOscillator", "ao", self.ao.Current.Value)
            # Plot all attributes of self.ao
            self.Plot("AwesomeOscillator", "slowao", self.ao.SlowAo.Current.Value)
            self.Plot("AwesomeOscillator", "fastao", self.ao.FastAo.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class AwesomeOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ao = AwesomeOscillator(10, 20, MovingAverageType.Simple)
        self.RegisterIndicator(self.symbol, self.ao, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.ao.IsReady:
            # The current value of self.ao is represented by self.ao.Current.Value
            self.Plot("AwesomeOscillator", "ao", self.ao.Current.Value)
            # Plot all attributes of self.ao
            self.Plot("AwesomeOscillator", "slowao", self.ao.SlowAo.Current.Value)
            self.Plot("AwesomeOscillator", "fastao", self.ao.FastAo.Current.Value)
```

The following reference table describes the `AwesomeOscillator` constructor:

INDICATORS

AwesomeOscillator() 1/2

```
AwesomeOscillator QuantConnect.Indicators.AwesomeOscillator (
int fastPeriod,
int slowPeriod
)
```

Creates a new Awesome Oscillator from the specified periods.

Show Details

Parameters		
int	fastPeriod	The period of the fast moving average associated with the AO.
int	slowPeriod	The period of the slow moving average associated with the AO.

Return

`AwesomeOscillator` - The new `AwesomeOscillator` indicator object.

Definition at line 57 of file Indicators/AwesomeOscillator.cs.

INDICATORS

Balance Of Power

Introduction

This indicator computes the Balance Of Power (BOP). The Balance Of Power is calculated with the following formula: BOP = (Close - Open) / (High - Low)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using BOP Indicator

To create an automatic indicators for `BalanceOfPower` , call the `BOP` helper method from the `QCAlgorithm` class. The `BOP` method creates a `BalanceOfPower` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
class BalanceOfPowerAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.bop = self.BOP(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.bop.IsReady:
            # The current value of self.bop is represented by self.bop.Current.Value
            self.Plot("BalanceOfPower", "bop", self.bop.Current.Value)
```

The following reference table describes the `BOP` method:

INDICATORS

BOP() 1/1

```
BalanceOfPower QuantConnect.Algorithm.QCAlgorithm.BOP (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Balance Of Power indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Balance Of Power we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`BalanceOfPower` - The Balance Of Power indicator for the requested symbol.

Definition at line 337 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `BalanceOfPower` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class BalanceOfPowerAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.bop = BalanceOfPower()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.bop.Update(bar)

        if self.bop.IsReady:
            # The current value of self.bop is represented by self.bop.Current.Value
            self.Plot("BalanceOfPower", "bop", self.bop.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class BalanceOfPowerAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.bop = BalanceOfPower()
        self.RegisterIndicator(self.symbol, self.bop, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.bop.IsReady:
            # The current value of self.bop is represented by self.bop.Current.Value
            self.Plot("BalanceOfPower", "bop", self.bop.Current.Value)
```

The following reference table describes the `BalanceOfPower` constructor:

INDICATORS

BalanceOfPower() 1/2

```
BalanceOfPower QuantConnect.Indicators.BalanceOfPower (

)
```

Initializes a new instance of the `BalanceOfPowe` class using the specified name.

Show Details

This method requires no argument input.

Return

`BalanceOfPower` - The new `BalanceOfPower` indicator object.

Definition at line 30 of file Indicators/BalanceOfPower.cs.

INDICATORS

BalanceOfPower() 2/2

```
BalanceOfPower QuantConnect.Indicators.BalanceOfPower (
string name
)
```

Initializes a new instance of the `BalanceOfPowe` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

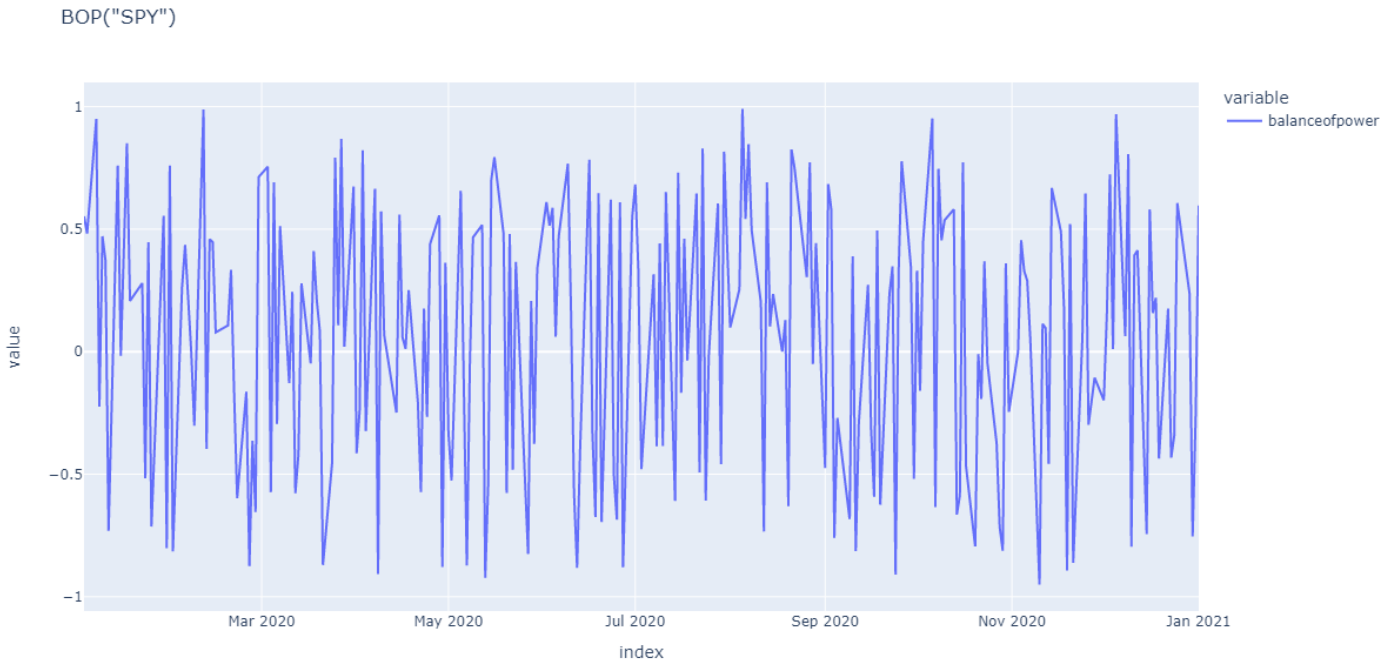
Return

`BalanceOfPower` - The new `BalanceOfPower` indicator object.

Definition at line 39 of file Indicators/BalanceOfPower.cs.

Visualization

The following image shows plot values of selected properties of `BalanceOfPower` using the plotly library.



Supported Indicators

Beta

Introduction

In technical analysis Beta indicator is used to measure volatility or risk of a target (ETF) relative to the overall risk (volatility) of the reference (market indexes). The Beta indicators compares target's price movement to the movements of the indexes over the same period of time. It is common practice to use the SPX index as a benchmark of the overall reference market when it comes to Beta calculations.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using B Indicator

To create an automatic indicators for `Beta` , call the `B` helper method from the `QCAlgorithm` class. The `B` method creates a `Beta` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class BetaAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.b = self.B(Symbol.Create("QQQ", SecurityType.Equity, Market.USA), self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.b.IsReady:
            # The current value of self.b is represented by self.b.Current.Value
            self.Plot("Beta", "b", self.b.Current.Value)
```

The following reference table describes the `B` method:

INDICATORS

B() 1/1

```
Beta QuantConnect.Algorithm.QCAlgorithm.B (
Symbol target,
Symbol reference,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a Beta indicator for the given target symbol in relation with the reference used. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	target	The target symbol whose Beta value we want.
`Symbol`	reference	The reference symbol to compare with the target symbol.
`Int32`	period	The period of the Beta indicator.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`Beta` - The Beta indicator for the given parameters.

Definition at line 318 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Beta` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class BetaAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.b = Beta("", 20, Symbol.Create("QQQ", SecurityType.Equity, Market.USA), Symbol.Create("SPY",
SecurityType.Equity, Market.USA))

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.b.Update(bar)

        if self.b.IsReady:
            # The current value of self.b is represented by self.b.Current.Value
            self.Plot("Beta", "b", self.b.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class BetaAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.b = Beta("", 20, Symbol.Create("QQQ", SecurityType.Equity, Market.USA), Symbol.Create("SPY",
SecurityType.Equity, Market.USA))
        self.RegisterIndicator(self.symbol, self.b, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.b.IsReady:
            # The current value of self.b is represented by self.b.Current.Value
            self.Plot("Beta", "b", self.b.Current.Value)
```

The following reference table describes the `Beta` constructor:

INDICATORS

Beta() 1/1

```
Beta QuantConnect.Indicators.Beta (
string name,
int period,
Symbol targetSymbol,
Symbol referenceSymbol
)
```

reference values.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of this indicator.
`Symbol`	targetSymbol	The target symbol of this indicator.
`Symbol`	referenceSymbol	The reference symbol of this indicator.

Return

`Beta` - The new `Beta` indicator object.

Visualization

The following image shows plot values of selected properties of `Beta` using the plotly library.

Supported Indicators

Bollinger Bands

Introduction

This indicator creates a moving average (middle band) with an upper band and lower band fixed at k standard deviations above and below the moving average.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using BB Indicator

To create an automatic indicators for `BollingerBands` , call the `BB` helper method from the `QCAlgorithm` class. The `BB` method creates a `BollingerBands` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class BollingerBandsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.bb = self.BB(self.symbol, 30, 2)

    def OnData(self, slice: Slice) -> None:
        if self.bb.IsReady:
            # The current value of self.bb is represented by self.bb.Current.Value
            self.Plot("BollingerBands", "bb", self.bb.Current.Value)
            # Plot all attributes of self.bb
            self.Plot("BollingerBands", "standarddeviation", self.bb.StandardDeviation.Current.Value)
            self.Plot("BollingerBands", "middleband", self.bb.MiddleBand.Current.Value)
            self.Plot("BollingerBands", "upperband", self.bb.UpperBand.Current.Value)
            self.Plot("BollingerBands", "lowerband", self.bb.LowerBand.Current.Value)
            self.Plot("BollingerBands", "bandwidth", self.bb.BandWidth.Current.Value)
            self.Plot("BollingerBands", "percentb", self.bb.PercentB.Current.Value)
            self.Plot("BollingerBands", "price", self.bb.Price.Current.Value)
```

The following reference table describes the `BB` method:

INDICATORS

BB() 1/1

```
BollingerBands QuantConnect.Algorithm.QCAlgorithm.BB (
Symbol symbol,
Int32 period,
Decimal k,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new BollingerBands indicator which will compute the MiddleBand, UpperBand, LowerBand, and StandardDeviation.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose BollingerBands we seek.
`Int32`	period	The period of the standard deviation and moving average (middle band).
`Decimal`	k	The number of standard deviations specifying the distance between the middle band and upper or lower bands.
`*MovingAverageType`	movingAverageType	*(Optional)* The type of moving average to be used.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`BollingerBands` - A BollingerBands configured with the specified period.

Definition at line 297 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `BollingerBands` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class BollingerBandsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.bb = BollingerBands(30, 2)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.bb.Update(bar.EndTime, bar.Close)

        if self.bb.IsReady:
            # The current value of self.bb is represented by self.bb.Current.Value
            self.Plot("BollingerBands", "bb", self.bb.Current.Value)
            # Plot all attributes of self.bb
            self.Plot("BollingerBands", "standarddeviation", self.bb.StandardDeviation.Current.Value)
            self.Plot("BollingerBands", "middleband", self.bb.MiddleBand.Current.Value)
            self.Plot("BollingerBands", "upperband", self.bb.UpperBand.Current.Value)
            self.Plot("BollingerBands", "lowerband", self.bb.LowerBand.Current.Value)
            self.Plot("BollingerBands", "bandwidth", self.bb.BandWidth.Current.Value)
            self.Plot("BollingerBands", "percentb", self.bb.PercentB.Current.Value)
            self.Plot("BollingerBands", "price", self.bb.Price.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class BollingerBandsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.bb = BollingerBands(30, 2)
        self.RegisterIndicator(self.symbol, self.bb, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.bb.IsReady:
            # The current value of self.bb is represented by self.bb.Current.Value
            self.Plot("BollingerBands", "bb", self.bb.Current.Value)
            # Plot all attributes of self.bb
            self.Plot("BollingerBands", "standarddeviation", self.bb.StandardDeviation.Current.Value)
            self.Plot("BollingerBands", "middleband", self.bb.MiddleBand.Current.Value)
            self.Plot("BollingerBands", "upperband", self.bb.UpperBand.Current.Value)
            self.Plot("BollingerBands", "lowerband", self.bb.LowerBand.Current.Value)
            self.Plot("BollingerBands", "bandwidth", self.bb.BandWidth.Current.Value)
            self.Plot("BollingerBands", "percentb", self.bb.PercentB.Current.Value)
            self.Plot("BollingerBands", "price", self.bb.Price.Current.Value)
```

The following reference table describes the `BollingerBands` constructor:

INDICATORS

BollingerBands() 1/2

```
BollingerBands QuantConnect.Indicators.BollingerBands (
int period,
decimal k,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the BollingerBands class.

Show Details

Parameters		
int	period	The period of the standard deviation and moving average (middle band).
decimal	k	The number of standard deviations specifying the distance between the middle band and upper or lower bands.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of moving average to be used. Default: MovingAverageType.Simple.

Return

`BollingerBands` - The new `BollingerBands` indicator object.

Chaikin Money Flow

Introduction

The Chaikin Money Flow Index (CMF) is a volume-weighted average of accumulation and distribution over a specified period. CMF = n-day Sum of [(((C - L) - (H - C)) / (H - L)) x Vol] / n-day Sum of Vol Where: n = number of periods, typically 21 H = high L = low C = close Vol = volume https://www.fidelity.com/learning-center/trading-investing/technical-analysis/technical-indicator-guide/cmf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CMF Indicator

To create an automatic indicators for `ChaikinMoneyFlow` , call the `CMF` helper method from the `QCAlgorithm` class. The `CMF` method creates a `ChaikinMoneyFlow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ChaikinMoneyFlowAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.cmf = self.CMF(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.cmf.IsReady:
            # The current value of self.cmf is represented by self.cmf.Current.Value
            self.Plot("ChaikinMoneyFlow", "cmf", self.cmf.Current.Value)
```

The following reference table describes the `CMF` method:

INDICATORS

CMF() 1/1

```
ChaikinMoneyFlow QuantConnect.Algorithm.QCAlgorithm.CMF (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new ChaikinMoneyFlow indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose CMF we want.
`Int32`	period	The period over which to compute the CMF.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`ChaikinMoneyFlow` - The ChaikinMoneyFlow indicator for the requested symbol over the specified period.

Definition at line 396 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

Chande Momentum Oscillator

Introduction

This indicator computes the Chande Momentum Oscillator (CMO). CMO calculation is mostly identical to RSI. The only difference is in the last step of calculation: RSI = gain / (gain+loss) CMO = (gain-loss) / (gain+loss)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CMO Indicator

To create an automatic indicators for `ChandeMomentumOscillator` , call the `CMO` helper method from the `QCAlgorithm` class. The `CMO` method creates a `ChandeMomentumOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ChandeMomentumOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.cmo = self.CMO(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.cmo.IsReady:
            # The current value of self.cmo is represented by self.cmo.Current.Value
            self.Plot("ChandeMomentumOscillator", "cmo", self.cmo.Current.Value)
```

The following reference table describes the `CMO` method:

INDICATORS

CMO() 1/1

```
ChandeMomentumOscillator QuantConnect.Algorithm.QCAlgorithm.CMO (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new ChandeMomentumOscillator indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose CMO we want.
`Int32`	period	The period over which to compute the CMO.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`ChandeMomentumOscillator` - The ChandeMomentumOscillator indicator for the requested symbol over the specified period.

Definition at line 415 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ChandeMomentumOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class ChandeMomentumOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.cmo = ChandeMomentumOscillator(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.cmo.Update(bar.EndTime, bar.Close)

        if self.cmo.IsReady:
            # The current value of self.cmo is represented by self.cmo.Current.Value
            self.Plot("ChandeMomentumOscillator", "cmo", self.cmo.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class ChandeMomentumOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.cmo = ChandeMomentumOscillator(20)
        self.RegisterIndicator(self.symbol, self.cmo, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.cmo.IsReady:
            # The current value of self.cmo is represented by self.cmo.Current.Value
            self.Plot("ChandeMomentumOscillator", "cmo", self.cmo.Current.Value)
```

The following reference table describes the `ChandeMomentumOscillator` constructor:

INDICATORS

ChandeMomentumOscillator() 1/2

```
ChandeMomentumOscillator QuantConnect.Indicators.ChandeMomentumOscillator (
int period
)
```

Initializes a new instance of the `ChandeMomentumOscillato` class using the specified period.

Show Details

Parameters		
int	period	The period of the indicator.

Return

`ChandeMomentumOscillator` - The new `ChandeMomentumOscillator` indicator object.

Definition at line 35 of file Indicators/ChandeMomentumOscillator.cs.

INDICATORS

ChandeMomentumOscillator() 2/2

```
ChandeMomentumOscillator QuantConnect.Indicators.ChandeMomentumOscillator (
string name,
int period
)
```

Initializes a new instance of the `ChandeMomentumOscillato` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the indicator.

Return

`ChandeMomentumOscillator` - The new `ChandeMomentumOscillator` indicator object.

Commodity Channel Index

Introduction

This indicator represents the traditional commodity channel index (CCI) CCI = (Typical Price - 20-period SMA of TP) / (.015 * Mean Deviation) Typical Price (TP) = (High + Low + Close)/3 Constant = 0.015 There are four steps to calculating the Mean Deviation, first, subtract the most recent 20-period average of the typical price from each period's typical price. Second, take the absolute values of these numbers. Third, sum the absolute values. Fourth, divide by the total number of periods (20).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CCI Indicator

To create an automatic indicators for `CommodityChannelIndex` , call the `CCI` helper method from the `QCAlgorithm` class. The `CCI` method creates a `CommodityChannelIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class CommodityChannelIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.cci = self.CCI(self.symbol, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.cci.IsReady:
            # The current value of self.cci is represented by self.cci.Current.Value
            self.Plot("CommodityChannelIndex", "cci", self.cci.Current.Value)
            # Plot all attributes of self.cci
            self.Plot("CommodityChannelIndex", "typicalpriceaverage",
self.cci.TypicalPriceAverage.Current.Value)
            self.Plot("CommodityChannelIndex", "typicalpricemeandeviation",
self.cci.TypicalPriceMeanDeviation.Current.Value)
```

The following reference table describes the `CCI` method:

INDICATORS

CCI() 1/1

```
CommodityChannelIndex QuantConnect.Algorithm.QCAlgorithm.CCI (
Symbol symbol,
Int32 period,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new CommodityChannelIndex indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose CCI we want.
`Int32`	period	The period over which to compute the CCI.
`*MovingAverageType`	movingAverageType	*(Optional)* The type of moving average to use in computing the typical price average.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`CommodityChannelIndex` - The CommodityChannelIndex indicator for the requested symbol over the specified period.

Definition at line 378 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `CommodityChannelIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```py
class CommodityChannelIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.cci = CommodityChannelIndex(20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.cci.Update(bar)

        if self.cci.IsReady:
            # The current value of self.cci is represented by self.cci.Current.Value
            self.Plot("CommodityChannelIndex", "cci", self.cci.Current.Value)
            # Plot all attributes of self.cci
            self.Plot("CommodityChannelIndex", "typicalpriceaverage",
self.cci.TypicalPriceAverage.Current.Value)
            self.Plot("CommodityChannelIndex", "typicalpricemeandeviation",
self.cci.TypicalPriceMeanDeviation.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class CommodityChannelIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.cci = CommodityChannelIndex(20, MovingAverageType.Simple)
        self.RegisterIndicator(self.symbol, self.cci, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.cci.IsReady:
            # The current value of self.cci is represented by self.cci.Current.Value
            self.Plot("CommodityChannelIndex", "cci", self.cci.Current.Value)
            # Plot all attributes of self.cci
            self.Plot("CommodityChannelIndex", "typicalpriceaverage",
self.cci.TypicalPriceAverage.Current.Value)
            self.Plot("CommodityChannelIndex", "typicalpricemeandeviation",
self.cci.TypicalPriceMeanDeviation.Current.Value)
```

The following reference table describes the `CommodityChannelIndex` constructor:

INDICATORS

CommodityChannelIndex() 1/2

```
CommodityChannelIndex QuantConnect.Indicators.CommodityChannelIndex (
int period,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the CommodityChannelIndex class.

Show Details

Parameters		
int	period	The period of the standard deviation and moving average (middle band).
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of moving average to be used. Default: MovingAverageType.Simple.

Return

CommodityChannelIndex - The new CommodityChannelIndex indicator object.

Definition at line 59 of file Indicators/CommodityChannelIndex.cs.

INDICATORS

CommodityChannelIndex() 2/2

```
CommodityChannelIndex QuantConnect.Indicators.CommodityChannelIndex (
string name,
int period,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the CommodityChannelIndex class.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the standard deviation and moving average (middle band).
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of moving average to be used. Default: MovingAverageType.Simple.

Return

CommodityChannelIndex - The new CommodityChannelIndex indicator object.

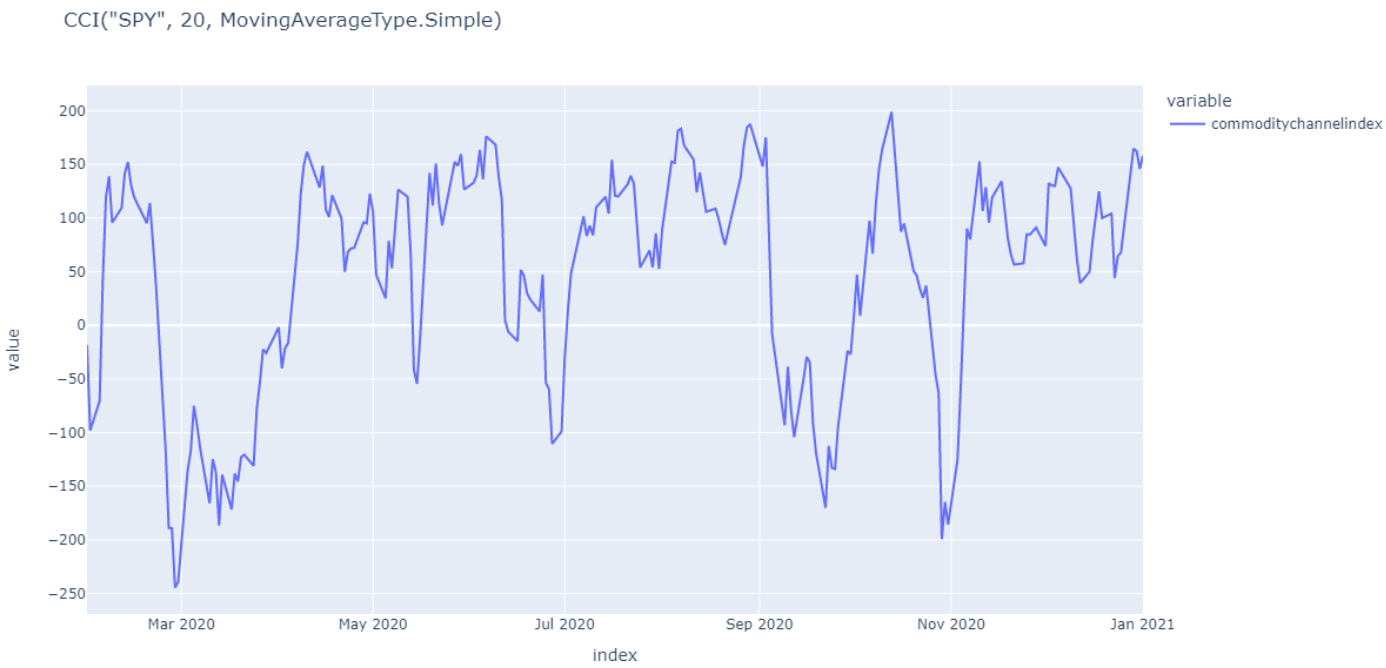
The following image shows plot values of selected properties of `CommodityChannelIndex` using the plotly library.



Supported Indicators

Coppock Curve

Introduction

A momentum indicator developed by Edwin “Sedge” Coppock in October 1965. The goal of this indicator is to identify long-term buying opportunities in the S&P500 and Dow Industrials. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CC Indicator

To create an automatic indicators for `CoppockCurve` , call the `CC` helper method from the `QCAlgorithm` class. The `CC` method creates a `CoppockCurve` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class CoppockCurveAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.cc = self.CC(self.symbol, 11, 14, 10)

    def OnData(self, slice: Slice) -> None:
        if self.cc.IsReady:
            # The current value of self.cc is represented by self.cc.Current.Value
            self.Plot("CoppockCurve", "cc", self.cc.Current.Value)
```

The following reference table describes the `CC` method:

INDICATORS

CC() 1/1

```
CoppockCurve QuantConnect.Algorithm.QCAlgorithm.CC (
Symbol symbol,
*Int32 shortRocPeriod,
*Int32 longRocPeriod,
*Int32 lwmaPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Initializes a new instance of the CoppockCurve" indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Coppock Curve we want.
`*Int32`	shortRocPeriod	*(Optional)* The period for the short ROC.
`*Int32`	longRocPeriod	*(Optional)* The period for the long ROC.
`*Int32`	lwmaPeriod	*(Optional)* The period for the LWMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`CoppockCurve` - The Coppock Curve indicator for the requested symbol over the specified period.

Definition at line 357 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

De Marker Indicator

Introduction

In the DeMarker strategy, for some period of size N, set: DeMax = High - Previous High, and DeMin = Previous Low - Low where, in the prior, if either term is less than zero (DeMax or DeMin), set it to zero. We can now define the indicator itself, DEM, as: DEM = MA(DeMax)/(MA(DeMax)+MA(DeMin)) where MA denotes a Moving Average of period N. https://www.investopedia.com/terms/d/demarkerindicator.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DEM Indicator

To create an automatic indicators for `DeMarkerIndicator` , call the `DEM` helper method from the `QCAlgorithm` class. The `DEM` method creates a `DeMarkerIndicator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class DeMarkerIndicatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dem = self.DEM(self.symbol, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.dem.IsReady:
            # The current value of self.dem is represented by self.dem.Current.Value
            self.Plot("DeMarkerIndicator", "dem", self.dem.Current.Value)
```

The following reference table describes the `DEM` method:

INDICATORS

DEM() 1/1

```
DeMarkerIndicator QuantConnect.Algorithm.QCAlgorithm.DEM (
Symbol symbol,
Int32 period,
MovingAverageType type,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new DeMarker Indicator (DEM), an oscillator-type indicator measuring changes in terms of an asset's High and Low tradebar values.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose DEM we seek.
`Int32`	period	The period of the moving average implemented.
`MovingAverageType`	type	Specifies the type of moving average to be used.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`DeMarkerIndicator` - The DeMarker indicator for the requested symbol.

Definition at line 435 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

Supported Indicators

Delay

Introduction

An indicator that delays its input for a certain period

To view the implementation of this indicator, see the LEAN GitHub repository .

Using Delay Indicator

Delay does not have an automatic indicator implementation available.

You can manually create a `Delay` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```
PY
class DelayAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.delay = Delay()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.delay.Update(bar.EndTime, bar.Close)

        if self.delay.IsReady:
            # The current value of self.delay is represented by self.delay.Current.Value
            self.Plot("Delay", "delay", self.delay.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
PY
class DelayAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.delay = Delay()
        self.RegisterIndicator(self.symbol, self.delay, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.delay.IsReady:
            # The current value of self.delay is represented by self.delay.Current.Value
            self.Plot("Delay", "delay", self.delay.Current.Value)
```

The following reference table describes the `Delay` constructor:

INDICATORS

Delay() 1/2

```
Delay QuantConnect.Indicators.Delay (
int period,
)
```

Initializes a new instance of the Delay class.

Show Details

Parameters		
int	period	The period to delay input, must be greater than zero.

Return

`Delay` - The new `Delay` indicator object.

Definition at line 27 of file Indicators/Delay.cs.

INDICATORS

Delay() 2/2

```
Delay QuantConnect.Indicators.Delay (
string name,
int period,
)
```

Initializes a new instance of the Delay class.

Show Details

Parameters		
string	name	Name of the delay window indicator.
int	period	The period to delay input, must be greater than zero.

Return

`Delay` - The new `Delay` indicator object.

Definition at line 37 of file Indicators/Delay.cs.

Visualization

The following image shows plot values of selected properties of `Delay` using the plotly library.

Supported Indicators

Detrended Price Oscillator

Introduction

The Detrended Price Oscillator is an indicator designed to remove trend from price and make it easier to identify cycles. DPO does not extend to the last date because it is based on a displaced moving average. Is estimated as Price {X/2 + 1} periods ago less the X-period simple moving average. E.g.DPO(20) equals price 11 days ago less the 20-day SMA.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DPO Indicator

To create an automatic indicators for `DetrendedPriceOscillator` , call the `DPO` helper method from the `QCAlgorithm` class. The `DPO` method creates a `DetrendedPriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class DetrendedPriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dpo = self.DPO(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.dpo.IsReady:
            # The current value of self.dpo is represented by self.dpo.Current.Value
            self.Plot("DetrendedPriceOscillator", "dpo", self.dpo.Current.Value)
```

The following reference table describes the `DPO` method:

INDICATORS

DPO() 1/1

```
DetrendedPriceOscillator QuantConnect.Algorithm.QCAlgorithm.DPO (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new DetrendedPriceOscillator" indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose DPO we want.
`Int32`	period	The period over which to compute the DPO.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`DetrendedPriceOscillator` - A new registered DetrendedPriceOscillator indicator for the requested symbol over the specified period.

Definition at line 505 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `DetrendedPriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class DetrendedPriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dpo = DetrendedPriceOscillator(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.dpo.Update(bar.EndTime, bar.Close)

        if self.dpo.IsReady:
            # The current value of self.dpo is represented by self.dpo.Current.Value
            self.Plot("DetrendedPriceOscillator", "dpo", self.dpo.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class DetrendedPriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dpo = DetrendedPriceOscillator(20)
        self.RegisterIndicator(self.symbol, self.dpo, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.dpo.IsReady:
            # The current value of self.dpo is represented by self.dpo.Current.Value
            self.Plot("DetrendedPriceOscillator", "dpo", self.dpo.Current.Value)
```

The following reference table describes the `DetrendedPriceOscillator` constructor:

INDICATORS

DetrendedPriceOscillator() 1/2

```
DetrendedPriceOscillator QuantConnect.Indicators.DetrendedPriceOscillator (
string name,
int period
)
```

Initializes a new instance of the `DetrendedPriceOscillator` class.

Show Details

Parameters		
`string`	name	The name for the indicator.
`int`	period	The number of periods to calculate the DPO.

Return

`DetrendedPriceOscillator` - The new `DetrendedPriceOscillator` indicator object.

Definition at line 46 of file Indicators/DetrendedPriceOscillator.cs.

INDICATORS

DetrendedPriceOscillator() 2/2

```
DetrendedPriceOscillator QuantConnect.Indicators.DetrendedPriceOscillator (
int period
)
```

Initializes a new instance of the `DetrendedPriceOscillator` class.

Show Details

Parameters		
`int`	period	The number of periods to calculate the DPO.

Return

`DetrendedPriceOscillator` - The new `DetrendedPriceOscillator` indicator object.

Definition at line 59 of file Indicators/DetrendedPriceOscillator.cs.

Supported Indicators

Donchian Channel

Introduction

This indicator computes the upper and lower band of the Donchian Channel. The upper band is computed by finding the highest high over the given period. The lower band is computed by finding the lowest low over the given period. The primary output value of the indicator is the mean of the upper and lower band for the given timeframe.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DCH Indicator

To create an automatic indicators for `DonchianChannel` , call the `DCH` helper method from the `QCAlgorithm` class. The `DCH` method creates a `DonchianChannel` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class DonchianChannelAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dch = self.DCH(self.symbol, 20, 20)

    def OnData(self, slice: Slice) -> None:
        if self.dch.IsReady:
            # The current value of self.dch is represented by self.dch.Current.Value
            self.Plot("DonchianChannel", "dch", self.dch.Current.Value)
            # Plot all attributes of self.dch
            self.Plot("DonchianChannel", "upperband", self.dch.UpperBand.Current.Value)
            self.Plot("DonchianChannel", "lowerband", self.dch.LowerBand.Current.Value)
```

The following reference table describes the `DCH` method:

INDICATORS

DCH() 1/2

```
DonchianChannel QuantConnect.Algorithm.QCAlgorithm.DCH (
 Symbol symbol,
 Int32 upperPeriod,
 Int32 lowerPeriod,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Donchian Channel indicator which will compute the Upper Band and Lower Band. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Donchian Channel we seek.
`Int32`	upperPeriod	The period over which to compute the upper Donchian Channel.
`Int32`	lowerPeriod	The period over which to compute the lower Donchian Channel.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`DonchianChannel` - The Donchian Channel indicator for the requested symbol.

Definition at line 454 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

DCH() 2/2

```
DonchianChannel QuantConnect.Algorithm.QCAlgorithm.DCH (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, IBaseDataBar> selector
)
```

Overload shorthand to create a new symmetric Donchian Channel indicator which has the upper and lower channels set to the same period length.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Donchian Channel we seek.
`Int32`	period	The period over which to compute the Donchian Channel.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`DonchianChannel` - The Donchian Channel indicator for the requested symbol.

Definition at line 473 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `DonchianChannel` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class DonchianChannelAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dch = DonchianChannel(20, 20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.dch.Update(bar)

        if self.dch.IsReady:
            # The current value of self.dch is represented by self.dch.Current.Value
            self.Plot("DonchianChannel", "dch", self.dch.Current.Value)
            # Plot all attributes of self.dch
            self.Plot("DonchianChannel", "upperband", self.dch.UpperBand.Current.Value)
            self.Plot("DonchianChannel", "lowerband", self.dch.LowerBand.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class DonchianChannelAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dch = DonchianChannel(20, 20)
        self.RegisterIndicator(self.symbol, self.dch, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.dch.IsReady:
            # The current value of self.dch is represented by self.dch.Current.Value
            self.Plot("DonchianChannel", "dch", self.dch.Current.Value)
            # Plot all attributes of self.dch
            self.Plot("DonchianChannel", "upperband", self.dch.UpperBand.Current.Value)
            self.Plot("DonchianChannel", "lowerband", self.dch.LowerBand.Current.Value)
```

The following reference table describes the `DonchianChannel` constructor:

INDICATORS

DonchianChannel() 1/4

```
DonchianChannel QuantConnect.Indicators.DonchianChannel (
int period
)
```

Initializes a new instance of the `DonchianChanne` class.

Double Exponential Moving Average

Introduction

This indicator computes the Double Exponential Moving Average (DEMA). The Double Exponential Moving Average is calculated with the following formula: EMA2 = EMA(EMA(t,period),period) DEMA = 2 * EMA(t,period) - EMA2 The Generalized DEMA (GD) is calculated with the following formula: GD = (volumeFactor+1) * EMA(t,period) - volumeFactor * EMA2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DEMA Indicator

To create an automatic indicators for `DoubleExponentialMovingAverage` , call the `DEMA` helper method from the `QCAlgorithm` class. The `DEMA` method creates a `DoubleExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
PY
class DoubleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dema = self.DEMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.dema.IsReady:
            # The current value of self.dema is represented by self.dema.Current.Value
            self.Plot("DoubleExponentialMovingAverage", "dema", self.dema.Current.Value)
```

The following reference table describes the `DEMA` method:

INDICATORS

DEMA() 1/1

```
DoubleExponentialMovingAverage QuantConnect.Algorithm.QCAlgorithm.DEMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new DoubleExponentialMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose DEMA we want.
`Int32`	period	The period over which to compute the DEMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`DoubleExponentialMovingAverage` - The DoubleExponentialMovingAverage indicator for the requested symbol over the specified period.

Definition at line 487 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `DoubleExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class DoubleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dema = DoubleExponentialMovingAverage(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.dema.Update(bar.EndTime, bar.Close)

        if self.dema.IsReady:
            # The current value of self.dema is represented by self.dema.Current.Value
            self.Plot("DoubleExponentialMovingAverage", "dema", self.dema.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class DoubleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.dema = DoubleExponentialMovingAverage(20)
        self.RegisterIndicator(self.symbol, self.dema, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.dema.IsReady:
            # The current value of self.dema is represented by self.dema.Current.Value
            self.Plot("DoubleExponentialMovingAverage", "dema", self.dema.Current.Value)
```

The following reference table describes the `DoubleExponentialMovingAverage` constructor:

INDICATORS

DoubleExponentialMovingAverage() 1/2

```
DoubleExponentialMovingAverage QuantConnect.Indicators.DoubleExponentialMovingAverage (
string name,
int period,
*decimal volumeFactor
)
```

Initializes a new instance of the `DoubleExponentialMovingAverag` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the DEMA.
`*decimal`	volumeFactor	*(Optional) (Optional)* The volume factor of the DEMA (value must be in the [0,1] range, set to 1 for standard DEMA). Default: 1m.

Return

`DoubleExponentialMovingAverage` - The new `DoubleExponentialMovingAverage` indicator object.

Definition at line 39 of file Indicators/DoubleExponentialMovingAverage.cs.

INDICATORS

DoubleExponentialMovingAverage() 2/2

```
DoubleExponentialMovingAverage QuantConnect.Indicators.DoubleExponentialMovingAverage (

Ease Of Movement Value

Introduction

This indicator computes the n-period Ease of Movement Value using the following: MID = (high_1 + low_1)/2 - (high_0 + low_0)/2 RATIO = (currentVolume/10000) / (high_1 - low_1) EMV = MID/RATIO _SMA = n-period of EMV Returns _SMA source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using EMV Indicator

To create an automatic indicators for `EaseOfMovementValue` , call the `EMV` helper method from the `QCAlgorithm` class. The `EMV` method creates a `EaseOfMovementValue` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class EaseOfMovementValueAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.emv = self.EMV(self.symbol, 1, 10000)

    def OnData(self, slice: Slice) -> None:
        if self.emv.IsReady:
            # The current value of self.emv is represented by self.emv.Current.Value
            self.Plot("EaseOfMovementValue", "emv", self.emv.Current.Value)
```

The following reference table describes the `EMV` method:

INDICATORS

EMV() 1/1

```
EaseOfMovementValue QuantConnect.Algorithm.QCAlgorithm.EMV (
Symbol symbol,
*Int32 period,
*Int32 scale,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an EaseOfMovementValue indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose EMV we want.
`*Int32`	period	*(Optional)* The period of the EMV.
`*Int32`	scale	*(Optional)* The length of the outputed value.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`EaseOfMovementValue` - The EaseOfMovementValue indicator for the given parameters.

Definition at line 560 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `EaseOfMovementValue` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class EaseOfMovementValueAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.emv = EaseOfMovementValue(1, 10000)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.emv.Update(bar)

        if self.emv.IsReady:
            # The current value of self.emv is represented by self.emv.Current.Value
            self.Plot("EaseOfMovementValue", "emv", self.emv.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class EaseOfMovementValueAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.emv = EaseOfMovementValue(1, 10000)
        self.RegisterIndicator(self.symbol, self.emv, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.emv.IsReady:
            # The current value of self.emv is represented by self.emv.Current.Value
            self.Plot("EaseOfMovementValue", "emv", self.emv.Current.Value)
```

The following reference table describes the `EaseOfMovementValue` constructor:

INDICATORS

EaseOfMovementValue() 1/2

```
EaseOfMovementValue QuantConnect.Indicators.EaseOfMovementValue (
*int period,
*int scale
)
```

Initializeds a new instance of the EaseOfMovement class using the specufued period.

Show Details

Parameters		
*int	period	*(Optional) (Optional)* The period over which to perform to computation. Default: 1.
*int	scale	*(Optional) (Optional)* The size of the number outputed by EMV. Default: 10000.

Return

`EaseOfMovementValue` - The new `EaseOfMovementValue` indicator object.

Definition at line 50 of file Indicators/EaseOfMovementValue.cs.

INDICATORS

EaseOfMovementValue() 2/2

```
EaseOfMovementValue QuantConnect.Indicators.EaseOfMovementValue (
string name,
int period,
int scale
)
```

Creates a new EaseOfMovement indicator with the specified period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period over which to perform to computation.
int	scale	The size of the number outputed by EMV.

Return

`EaseOfMovementValue` - The new `EaseOfMovementValue` indicator object.

Definition at line 60 of file Indicators/EaseOfMovementValue.cs.

Exponential Moving Average

Introduction

This indicator represents the traditional exponential moving average indicator (EMA). When the indicator is ready, the first value of the EMA is equivalent to the simple moving average. After the first EMA value, the EMA value is a function of the previous EMA value. Therefore, depending on the number of samples you feed into the indicator, it can provide different EMA values for a single security and lookback period. To make the indicator values consistent across time, warm up the indicator with all the trailing security price history.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using EMA Indicator

To create an automatic indicators for `ExponentialMovingAverage` , call the `EMA` helper method from the `QCAlgorithm` class. The `EMA` method creates a `ExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class ExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ema = self.EMA(self.symbol, 20, 0.5)

    def OnData(self, slice: Slice) -> None:
        if self.ema.IsReady:
            # The current value of self.ema is represented by self.ema.Current.Value
            self.Plot("ExponentialMovingAverage", "ema", self.ema.Current.Value)
```

The following reference table describes the `EMA` method:

INDICATORS

EMA() 1/2

```
ExponentialMovingAverage QuantConnect.Algorithm.QCAlgorithm.EMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates an ExponentialMovingAverage indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose EMA we want.
`Int32`	period	The period of the EMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`ExponentialMovingAverage` - The ExponentialMovingAverage for the given parameters.

Definition at line 524 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

EMA() 2/2

```
ExponentialMovingAverage QuantConnect.Algorithm.QCAlgorithm.EMA (
 Symbol symbol,
 Int32 period,
 Decimal smoothingFactor,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates an ExponentialMovingAverage indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose EMA we want.
`Int32`	period	The period of the EMA.
`Decimal`	smoothingFactor	The percentage of data from the previous value to be carried into the next value.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`ExponentialMovingAverage` - The ExponentialMovingAverage for the given parameters.

Definition at line 540 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class ExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ema = ExponentialMovingAverage(20, 0.5)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.ema.Update(bar.EndTime, bar.Close)

        if self.ema.IsReady:
            # The current value of self.ema is represented by self.ema.Current.Value
            self.Plot("ExponentialMovingAverage", "ema", self.ema.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class ExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ema = ExponentialMovingAverage(20, 0.5)
        self.RegisterIndicator(self.symbol, self.ema, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.ema.IsReady:
            # The current value of self.ema is represented by self.ema.Current.Value
            self.Plot("ExponentialMovingAverage", "ema", self.ema.Current.Value)
```

The following reference table describes the `ExponentialMovingAverage` constructor:

INDICATORS

ExponentialMovingAverage() 1/4

```
ExponentialMovingAverage QuantConnect.Indicators.ExponentialMovingAverage (
string name,
int period
)
```

Initializes a new instance of the ExponentialMovingAverage class with the specified name and period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the EMA.

Return

`ExponentialMovingAverage` - The new `ExponentialMovingAverage` indicator object.

Filtered Identity

Introduction

This indicator represents an indicator that is a ready after ingesting a single sample and always returns the same value as it is given if it passes a filter condition

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FilteredIdentity Indicator

To create an automatic indicators for `FilteredIdentity` , call the `FilteredIdentity` helper method from the `QCAlgorithm` class. The `FilteredIdentity` method creates a `FilteredIdentity` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
PY
class FilteredIdentityAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.filteredidentity = self.FilteredIdentity(self.symbol, filter = lambda x: x.Close > x.Open)

    def OnData(self, slice: Slice) -> None:
        if self.filteredidentity.IsReady:
            # The current value of self.filteredidentity is represented by
self.filteredidentity.Current.Value
            self.Plot("FilteredIdentity", "filteredidentity", self.filteredidentity.Current.Value)
```

The following reference table describes the `FilteredIdentity` method:

Warning: include(/tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/qcalgorithm-api/filteredidentity.html): failed to open stream: No such file or directory in /tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/indicators/using-indicator.php on line 49
Warning: include(): Failed opening '/tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/qcalgorithm-api/filteredidentity.html' for inclusion (include_path='/var/www/beta/core/libraries/Google:/var/www/beta:.:/usr/share/php') in /tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/indicators/using-indicator.php on line 49

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `FilteredIdentity` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to

update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class FilteredIdentityAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.filteredidentity = FilteredIdentity("SPY", filter = lambda x: x.Close > x.Open)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.filteredidentity.Update(bar.EndTime, bar.Close)

        if self.filteredidentity.IsReady:
            # The current value of self.filteredidentity is represented by
self.filteredidentity.Current.Value
            self.Plot("FilteredIdentity", "filteredidentity", self.filteredidentity.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class FilteredIdentityAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.filteredidentity = FilteredIdentity("SPY", filter = lambda x: x.Close > x.Open)
        self.RegisterIndicator(self.symbol, self.filteredidentity, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.filteredidentity.IsReady:
            # The current value of self.filteredidentity is represented by
self.filteredidentity.Current.Value
            self.Plot("FilteredIdentity", "filteredidentity", self.filteredidentity.Current.Value)
```

The following reference table describes the `FilteredIdentity` constructor:

INDICATORS

FilteredIdentity() 1/1

```
FilteredIdentity QuantConnect.Indicators.FilteredIdentity (
string name,
Func filter
)
```

Initializes a new instance of the FilteredIdentity indicator with the specified name.

Show Details

Parameters		
`string`	name	The name of the indicator.
`Func`	filter	Filters the IBaseData send into the indicator, if null defaults to true (x =.

Return

`FilteredIdentity` - The new `FilteredIdentity` indicator object.

Definition at line 36 of file Indicators/FilteredIdentity.cs.

Visualization

The following image shows plot values of selected properties of `FilteredIdentity` using the plotly library.

Fisher Transform

Introduction

The Fisher transform is a mathematical process which is used to convert any data set to a modified data set whose Probability Distribution Function is approximately Gaussian. Once the Fisher transform is computed, the transformed data can then be analyzed in terms of it's deviation from the mean. The equation is y = .5 * ln [1 + x / 1 - x] where x is the input y is the output ln is the natural logarithm The Fisher transform has much sharper turning points than other indicators such as MACD For more info, read chapter 1 of Cybernetic Analysis for Stocks and Futures by John F. Ehlers We are implementing the latest version of this indicator found at Fig. 4 of http://www.mesasoftware.com/papers/UsingTheFisherTransform.pdf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FISH Indicator

To create an automatic indicators for `FisherTransform` , call the `FISH` helper method from the `QCAlgorithm` class. The `FISH` method creates a `FisherTransform` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class FisherTransformAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.fish = self.FISH(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.fish.IsReady:
            # The current value of self.fish is represented by self.fish.Current.Value
            self.Plot("FisherTransform", "fish", self.fish.Current.Value)
```

The following reference table describes the `FISH` method:

INDICATORS

FISH() 1/1

```
FisherTransform QuantConnect.Algorithm.QCAlgorithm.FISH (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an FisherTransform indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose FisherTransform we want.
`Int32`	period	The period of the FisherTransform.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`FisherTransform` - The FisherTransform for the given parameters.

Definition at line 633 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `FisherTransform` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```py
class FisherTransformAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.fish = FisherTransform(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.fish.Update(bar)

        if self.fish.IsReady:
            # The current value of self.fish is represented by self.fish.Current.Value
            self.Plot("FisherTransform", "fish", self.fish.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class FisherTransformAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.fish = FisherTransform(20)
        self.RegisterIndicator(self.symbol, self.fish, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.fish.IsReady:
            # The current value of self.fish is represented by self.fish.Current.Value
            self.Plot("FisherTransform", "fish", self.fish.Current.Value)
```

The following reference table describes the `FisherTransform` constructor:

INDICATORS

FisherTransform() 1/2

```
FisherTransform QuantConnect.Indicators.FisherTransform (
int period
)
```

Initializes a new instance of the FisherTransform class with the default name and period.

Show Details

Parameters		
int	period	The period of the WMA.

Return

`FisherTransform` - The new `FisherTransform` indicator object.

Definition at line 50 of file Indicators/FisherTransform.cs.

INDICATORS

FisherTransform() 2/2

```
FisherTransform QuantConnect.Indicators.FisherTransform (
string name,
int period
)
```

A Fisher Transform of Prices.

Show Details

Parameters		
string	name	string - the name of the indicator.
int	period	The number of periods for the indicator.

Return

FisherTransform - The new FisherTransform indicator object.

Definition at line 60 of file Indicators/FisherTransform.cs.

Fractal Adaptive Moving Average

Introduction

The Fractal Adaptive Moving Average (FRAMA) by John Ehlers

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FRAMA Indicator

To create an automatic indicators for `FractalAdaptiveMovingAverage` , call the `FRAMA` helper method from the `QCAlgorithm` class. The `FRAMA` method creates a `FractalAdaptiveMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
class FractalAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.frama = self.FRAMA(self.symbol, 20, 198)

    def OnData(self, slice: Slice) -> None:
        if self.frama.IsReady:
            # The current value of self.frama is represented by self.frama.Current.Value
            self.Plot("FractalAdaptiveMovingAverage", "frama", self.frama.Current.Value)
```

The following reference table describes the `FRAMA` method:

INDICATORS

FRAMA() 1/1

```
FractalAdaptiveMovingAverage QuantConnect.Algorithm.QCAlgorithm.FRAMA (
Symbol symbol,
Int32 period,
*Int32 longPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates an FractalAdaptiveMovingAverage (FRAMA) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose FRAMA we want.
`Int32`	period	The period of the FRAMA.
`*Int32`	longPeriod	*(Optional)* The long period of the FRAMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`FractalAdaptiveMovingAverage` - The FRAMA for the given parameters.

Definition at line 653 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `FractalAdaptiveMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class FractalAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.frama = FractalAdaptiveMovingAverage(20, 198)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.frama.Update(bar)

        if self.frama.IsReady:
            # The current value of self.frama is represented by self.frama.Current.Value
            self.Plot("FractalAdaptiveMovingAverage", "frama", self.frama.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class FractalAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.frama = FractalAdaptiveMovingAverage(20, 198)
        self.RegisterIndicator(self.symbol, self.frama, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.frama.IsReady:
            # The current value of self.frama is represented by self.frama.Current.Value
            self.Plot("FractalAdaptiveMovingAverage", "frama", self.frama.Current.Value)
```

The following reference table describes the `FractalAdaptiveMovingAverage` constructor:

INDICATORS

FractalAdaptiveMovingAverage() 1/3

```
FractalAdaptiveMovingAverage QuantConnect.Indicators.FractalAdaptiveMovingAverage (
string name,
int n,
int longPeriod
)
```

Initializes a new instance of the average class.

Show Details

Parameters		
`string`	name	The name of the indicator instance.
`int`	n	The window period (must be even). Example value: 16.
`int`	longPeriod	The average period. Example value: 198.

Return

`FractalAdaptiveMovingAverage` - The new `FractalAdaptiveMovingAverage` indicator object.

Definition at line 38 of file Indicators/FractalAdaptiveMovingAverage.cs.

INDICATORS

FractalAdaptiveMovingAverage() 2/3

```
FractalAdaptiveMovingAverage QuantConnect.Indicators.FractalAdaptiveMovingAverage (
int n,
int longPeriod
)
```

Initializes a new instance of the average class.

Show Details

Parameters		
int	n	The window period (must be even). Example value: 16.
int	longPeriod	The average period. Example value: 198.

Return

`FractalAdaptiveMovingAverage` - The new `FractalAdaptiveMovingAverage` indicator object.

Definition at line 56 of file Indicators/FractalAdaptiveMovingAverage.cs.

INDICATORS

FractalAdaptiveMovingAverage() 3/3

```
FractalAdaptiveMovingAverage QuantConnect.Indicators.FractalAdaptiveMovingAverage (

Heikin Ashi

Introduction

This indicator computes the Heikin-Ashi bar (HA) The Heikin-Ashi bar is calculated using the following formulas: HA_Close[0] = (Open[0] + High[0] + Low[0] + Close[0]) / 4 HA_Open[0] = (HA_Open[1] + HA_Close[1]) / 2 HA_High[0] = MAX(High[0], HA_Open[0], HA_Close[0]) HA_Low[0] = MIN(Low[0], HA_Open[0], HA_Close[0])

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HeikinAshi Indicator

To create an automatic indicators for `HeikinAshi` , call the `HeikinAshi` helper method from the `QCAlgorithm` class. The `HeikinAshi` method creates a `HeikinAshi` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
class HeikinAshiAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.heikinashi = self.HeikinAshi(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.heikinashi.IsReady:
            # The current value of self.heikinashi is represented by self.heikinashi.Current.Value
            self.Plot("HeikinAshi", "heikinashi", self.heikinashi.Current.Value)
            # Plot all attributes of self.heikinashi
            self.Plot("HeikinAshi", "open", self.heikinashi.Open.Current.Value)
            self.Plot("HeikinAshi", "high", self.heikinashi.High.Current.Value)
            self.Plot("HeikinAshi", "low", self.heikinashi.Low.Current.Value)
            self.Plot("HeikinAshi", "close", self.heikinashi.Close.Current.Value)
            self.Plot("HeikinAshi", "volume", self.heikinashi.Volume.Current.Value)
```

The following reference table describes the `HeikinAshi` method:

Warning: include(/tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/qcalgorithm-api/heikinashi.html): failed to open stream: No such file or directory in /tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/indicators/using-indicator.php on line 49
Warning: include(): Failed opening '/tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/qcalgorithm-api/heikinashi.html' for inclusion (include_path='/var/www/beta/core/libraries/Google:/var/www/beta:.:/usr/share/php') in /tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/indicators/using-indicator.php on line 49

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `HeikinAshi` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```py
class HeikinAshiAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.heikinashi = HeikinAshi()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.heikinashi.Update(bar)

        if self.heikinashi.IsReady:
            # The current value of self.heikinashi is represented by self.heikinashi.Current.Value
            self.Plot("HeikinAshi", "heikinashi", self.heikinashi.Current.Value)
            # Plot all attributes of self.heikinashi
            self.Plot("HeikinAshi", "open", self.heikinashi.Open.Current.Value)
            self.Plot("HeikinAshi", "high", self.heikinashi.High.Current.Value)
            self.Plot("HeikinAshi", "low", self.heikinashi.Low.Current.Value)
            self.Plot("HeikinAshi", "close", self.heikinashi.Close.Current.Value)
            self.Plot("HeikinAshi", "volume", self.heikinashi.Volume.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class HeikinAshiAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.heikinashi = HeikinAshi()
        self.RegisterIndicator(self.symbol, self.heikinashi, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.heikinashi.IsReady:
            # The current value of self.heikinashi is represented by self.heikinashi.Current.Value
            self.Plot("HeikinAshi", "heikinashi", self.heikinashi.Current.Value)
            # Plot all attributes of self.heikinashi
            self.Plot("HeikinAshi", "open", self.heikinashi.Open.Current.Value)
            self.Plot("HeikinAshi", "high", self.heikinashi.High.Current.Value)
            self.Plot("HeikinAshi", "low", self.heikinashi.Low.Current.Value)
            self.Plot("HeikinAshi", "close", self.heikinashi.Close.Current.Value)
            self.Plot("HeikinAshi", "volume", self.heikinashi.Volume.Current.Value)
```

The following reference table describes the `HeikinAshi` constructor:

INDICATORS

HeikinAshi() 1/2

```
HeikinAshi QuantConnect.Indicators.HeikinAshi (
string name
)
```

Initializes a new instance of the `HeikinAsh` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`HeikinAshi` - The new `HeikinAshi` indicator object.

Definition at line 60 of file Indicators/HeikinAshi.cs.

INDICATORS

HeikinAshi() 2/2

```
HeikinAshi QuantConnect.Indicators.HeikinAshi (
)
```

Initializes a new instance of the `HeikinAsh` class.

Show Details

This method requires no argument input.

Return

`HeikinAshi` - The new `HeikinAshi` indicator object.

Definition at line 73 of file Indicators/HeikinAshi.cs.

Hilbert Transform

Introduction

This indicator computes the Hilbert Transform Indicator by John Ehlers. By using present and prior price differences, and some feedback, price values are split into their complex number components of real (inPhase) and imaginary (quadrature) parts. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HilbertTransform Indicator

To create an automatic indicators for `HilbertTransform` , call the `HilbertTransform` helper method from the `QCAlgorithm` class. The `HilbertTransform` method creates a `HilbertTransform` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
class HilbertTransformAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hilberttransform = self.HilbertTransform(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.hilberttransform.IsReady:
            # The current value of self.hilberttransform is represented by
self.hilberttransform.Current.Value
            self.Plot("HilbertTransform", "hilberttransform", self.hilberttransform.Current.Value)
            # Plot all attributes of self.hilberttransform
            self.Plot("HilbertTransform", "inphase", self.hilberttransform.InPhase.Current.Value)
            self.Plot("HilbertTransform", "quadrature", self.hilberttransform.Quadrature.Current.Value)
```

The following reference table describes the `HilbertTransform` method:

Warning: include(/tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/qcalgorithm-api/hilberttransform.html): failed to open stream: No such file or directory in /tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/indicators/using-indicator.php on line 49
Warning: include(): Failed opening '/tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/qcalgorithm-api/hilberttransform.html' for inclusion (include_path='/var/www/beta/core/libraries/Google:/var/www/beta:.:/usr/share/php') in /tmp/docs/227df3f244543bb12dcd97f1827791c4d3960ab7/Resources/indicators/using-indicator.php on line 49

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `HilbertTransform` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```
PY
class HilbertTransformAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hilberttransform = HilbertTransform()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.hilberttransform.Update(bar.EndTime, bar.Close)

        if self.hilberttransform.IsReady:
            # The current value of self.hilberttransform is represented by
self.hilberttransform.Current.Value
            self.Plot("HilbertTransform", "hilberttransform", self.hilberttransform.Current.Value)
            # Plot all attributes of self.hilberttransform
            self.Plot("HilbertTransform", "inphase", self.hilberttransform.InPhase.Current.Value)
            self.Plot("HilbertTransform", "quadrature", self.hilberttransform.Quadrature.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
PY
class HilbertTransformAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hilberttransform = HilbertTransform()
        self.RegisterIndicator(self.symbol, self.hilberttransform, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.hilberttransform.IsReady:
            # The current value of self.hilberttransform is represented by
self.hilberttransform.Current.Value
            self.Plot("HilbertTransform", "hilberttransform", self.hilberttransform.Current.Value)
            # Plot all attributes of self.hilberttransform
            self.Plot("HilbertTransform", "inphase", self.hilberttransform.InPhase.Current.Value)
            self.Plot("HilbertTransform", "quadrature", self.hilberttransform.Quadrature.Current.Value)
```

The following reference table describes the `HilbertTransform` constructor:

INDICATORS

HilbertTransform() 1/2

```
HilbertTransform QuantConnect.Indicators.HilbertTransform (
string name
)
```

Creates a new Hilbert Transform indicator.

Show Details

Parameters		
`string`	name	The name of this indicator.

Hull Moving Average

Introduction

Produces a Hull Moving Average as explained at http://www.alanhull.com/hull-moving-average/ and derived from the instructions for the Excel VBA code at http://finance4traders.blogspot.com/2009/06/how-to-calculate-hull-moving-average.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HMA Indicator

To create an automatic indicators for `HullMovingAverage` , call the `HMA` helper method from the `QCAlgorithm` class. The `HMA` method creates a `HullMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class HullMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hma = self.HMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.hma.IsReady:
            # The current value of self.hma is represented by self.hma.Current.Value
            self.Plot("HullMovingAverage", "hma", self.hma.Current.Value)
```

The following reference table describes the `HMA` method:

INDICATORS

HMA() 1/1

```
HullMovingAverage QuantConnect.Algorithm.QCAlgorithm.HMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new HullMovingAverage indicator. The Hull moving average is a series of nested weighted moving averages, is fast and smooth.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Hull moving average we want.
`Int32`	period	The period over which to compute the Hull moving average.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`HullMovingAverage` - The new `HullMovingAverage` object.

Definition at line 712 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `HullMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class HullMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hma = HullMovingAverage(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.hma.Update(bar.EndTime, bar.Close)

        if self.hma.IsReady:
            # The current value of self.hma is represented by self.hma.Current.Value
            self.Plot("HullMovingAverage", "hma", self.hma.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class HullMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.hma = HullMovingAverage(20)
        self.RegisterIndicator(self.symbol, self.hma, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.hma.IsReady:
            # The current value of self.hma is represented by self.hma.Current.Value
            self.Plot("HullMovingAverage", "hma", self.hma.Current.Value)
```

The following reference table describes the `HullMovingAverage` constructor:

INDICATORS

HullMovingAverage() 1/2

```
HullMovingAverage QuantConnect.Indicators.HullMovingAverage (
string name,
int period
)
```

A Hull Moving Average.

Show Details

Parameters		
`string`	name	string - a name for the indicator.
`int`	period	int - the number of periods to calculate the HMA - the period of the slower LWMA.

Return

`HullMovingAverage` - The new `HullMovingAverage` indicator object.

Definition at line 35 of file Indicators/HullMovingAverage.cs.

INDICATORS

HullMovingAverage() 2/2

```
HullMovingAverage QuantConnect.Indicators.HullMovingAverage (
int period
)
```

A Hull Moving Average.

Show Details

Parameters		
`int`	period	int - the number of periods over which to calculate the HMA - the length of the slower LWMA.

Return

`HullMovingAverage` - The new `HullMovingAverage` indicator object.

Definition at line 49 of file Indicators/HullMovingAverage.cs.

Supported Indicators

Ichimoku Kinko Hyo

Introduction

This indicator computes the Ichimoku Kinko Hyo indicator. It consists of the following main indicators: Tenkan-sen: (Highest High + Lowest Low) / 2 for the specific period (normally 9) Kijun-sen: (Highest High + Lowest Low) / 2 for the specific period (normally 26) Senkou A Span: (Tenkan-sen + Kijun-sen)/ 2 from a specific number of periods ago (normally 26) Senkou B Span: (Highest High + Lowest Low) / 2 for the specific period (normally 52), from a specific number of periods ago (normally 26)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ICHIMOKU Indicator

To create an automatic indicators for `IchimokuKinkoHyo` , call the `ICHIMOKU` helper method from the `QCAlgorithm` class. The `ICHIMOKU` method creates a `IchimokuKinkoHyo` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class IchimokuKinkoHyoAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ichimoku = self.ICHIMOKU(self.symbol, 9, 26, 17, 52, 26, 26)

    def OnData(self, slice: Slice) -> None:
        if self.ichimoku.IsReady:
            # The current value of self.ichimoku is represented by self.ichimoku.Current.Value
            self.Plot("IchimokuKinkoHyo", "ichimoku", self.ichimoku.Current.Value)
            # Plot all attributes of self.ichimoku
            self.Plot("IchimokuKinkoHyo", "tenkan", self.ichimoku.Tenkan.Current.Value)
            self.Plot("IchimokuKinkoHyo", "kijun", self.ichimoku.Kijun.Current.Value)
            self.Plot("IchimokuKinkoHyo", "senkoua", self.ichimoku.SenkouA.Current.Value)
            self.Plot("IchimokuKinkoHyo", "senkoub", self.ichimoku.SenkouB.Current.Value)
            self.Plot("IchimokuKinkoHyo", "chikou", self.ichimoku.Chikou.Current.Value)
            self.Plot("IchimokuKinkoHyo", "tenkanmaximum", self.ichimoku.TenkanMaximum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "tenkanminimum", self.ichimoku.TenkanMinimum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "kijunmaximum", self.ichimoku.KijunMaximum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "kijunminimum", self.ichimoku.KijunMinimum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "senkoubmaximum", self.ichimoku.SenkouBMaximum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "senkoubminimum", self.ichimoku.SenkouBMinimum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "delayedtenkansenkoua",
self.ichimoku.DelayedTenkanSenkouA.Current.Value)
            self.Plot("IchimokuKinkoHyo", "delayedkijunsenkoua",
self.ichimoku.DelayedKijunSenkouA.Current.Value)
            self.Plot("IchimokuKinkoHyo", "delayedmaximumsenkoub",
self.ichimoku.DelayedMaximumSenkouB.Current.Value)
            self.Plot("IchimokuKinkoHyo", "delayedminimumsenkoub",
self.ichimoku.DelayedMinimumSenkouB.Current.Value)
```

The following reference table describes the `ICHIMOKU` method:

INDICATORS

ICHIMOKU() 1/1

```
IchimokuKinkoHyo QuantConnect.Algorithm.QCAlgorithm.ICHIMOKU (
Symbol symbol,
Int32 tenkanPeriod,
Int32 kijunPeriod,
Int32 senkouAPeriod,
Int32 senkouBPeriod,
Int32 senkouADelayPeriod,
Int32 senkouBDelayPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new IchimokuKinkoHyo indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose ICHIMOKU we want.
Int32	tenkanPeriod	The period to calculate the Tenkan-sen period.
Int32	kijunPeriod	The period to calculate the Kijun-sen period.
Int32	senkouAPeriod	The period to calculate the Tenkan-sen period.
Int32	senkouBPeriod	The period to calculate the Tenkan-sen period.
Int32	senkouADelayPeriod	The period to calculate the Tenkan-sen period.
Int32	senkouBDelayPeriod	The period to calculate the Tenkan-sen period.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, TradeBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

IchimokuKinkoHyo - A new IchimokuKinkoHyo indicator with the specified periods and delays.

Definition at line 736 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update

its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `IchimokuKinkoHyo` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```
class IchimokuKinkoHyoAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ichimoku = IchimokuKinkoHyo(9, 26, 17, 52, 26, 26)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.ichimoku.Update(bar)

        if self.ichimoku.IsReady:
            # The current value of self.ichimoku is represented by self.ichimoku.Current.Value
            self.Plot("IchimokuKinkoHyo", "ichimoku", self.ichimoku.Current.Value)
            # Plot all attributes of self.ichimoku
            self.Plot("IchimokuKinkoHyo", "tenkan", self.ichimoku.Tenkan.Current.Value)
            self.Plot("IchimokuKinkoHyo", "kijun", self.ichimoku.Kijun.Current.Value)
            self.Plot("IchimokuKinkoHyo", "senkoua", self.ichimoku.SenkouA.Current.Value)
            self.Plot("IchimokuKinkoHyo", "senkoub", self.ichimoku.SenkouB.Current.Value)
            self.Plot("IchimokuKinkoHyo", "chikou", self.ichimoku.Chikou.Current.Value)
            self.Plot("IchimokuKinkoHyo", "tenkanmaximum", self.ichimoku.TenkanMaximum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "tenkanminimum", self.ichimoku.TenkanMinimum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "kijunmaximum", self.ichimoku.KijunMaximum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "kijunminimum", self.ichimoku.KijunMinimum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "senkoubmaximum", self.ichimoku.SenkouBMaximum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "senkoubminimum", self.ichimoku.SenkouBMinimum.Current.Value)
            self.Plot("IchimokuKinkoHyo", "delayedtenkansenkoua",
self.ichimoku.DelayedTenkanSenkouA.Current.Value)
            self.Plot("IchimokuKinkoHyo", "delayedkijunsenkoua",
self.ichimoku.DelayedKijunSenkouA.Current.Value)
            self.Plot("IchimokuKinkoHyo", "delayedmaximumsenkoub",
self.ichimoku.DelayedMaximumSenkouB.Current.Value)
            self.Plot("IchimokuKinkoHyo", "delayedminimumsenkoub",
self.ichimoku.DelayedMinimumSenkouB.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class IchimokuKinkoHyoAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ichimoku = IchimokuKinkoHyo(9, 26, 17, 52, 26, 26)
        self.RegisterIndicator(self.symbol, self.ichimoku, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.ichimoku.IsReady:

*int senkouBDelayPeriod
)
```

Creates a new IchimokuKinkoHyo indicator from the specific periods.

Show Details

Parameters		
*int	tenkanPeriod	*(Optional) (Optional)* The Tenkan-sen period. Default: 9.
*int	kijunPeriod	*(Optional) (Optional)* The Kijun-sen period. Default: 26.
*int	senkouAPeriod	*(Optional) (Optional)* The Senkou A Span period. Default: 26.
*int	senkouBPeriod	*(Optional) (Optional)* The Senkou B Span period. Default: 52.
*int	senkouADelayPeriod	*(Optional) (Optional)* The Senkou A Span delay. Default: 26.
*int	senkouBDelayPeriod	*(Optional) (Optional)* The Senkou B Span delay. Default: 26.

Return

`IchimokuKinkoHyo` - The new `IchimokuKinkoHyo` indicator object.

Definition at line 114 of file Indicators/IchimokuKinkoHyo.cs.

INDICATORS

IchimokuKinkoHyo() 2/2

```
IchimokuKinkoHyo QuantConnect.Indicators.IchimokuKinkoHyo (
 string name,
 *int tenkanPeriod,
 *int kijunPeriod,
 *int senkouAPeriod,
 *int senkouBPeriod,
 *int senkouADelayPeriod,
 *int senkouBDelayPeriod
)
```

Creates a new IchimokuKinkoHyo indicator from the specific periods.

Show Details

Parameters		
`string`	name	The name of this indicator.
`*int`	tenkanPeriod	*(Optional) (Optional)* The Tenkan-sen period. Default: 9.
`*int`	kijunPeriod	*(Optional) (Optional)* The Kijun-sen period. Default: 26.
`*int`	senkouAPeriod	*(Optional) (Optional)* The Senkou A Span period. Default: 26.
`*int`	senkouBPeriod	*(Optional) (Optional)* The Senkou B Span period. Default: 52.
`*int`	senkouADelayPeriod	*(Optional) (Optional)* The Senkou A Span delay. Default: 26.
`*int`	senkouBDelayPeriod	*(Optional) (Optional)* The Senkou B Span delay. Default: 26.

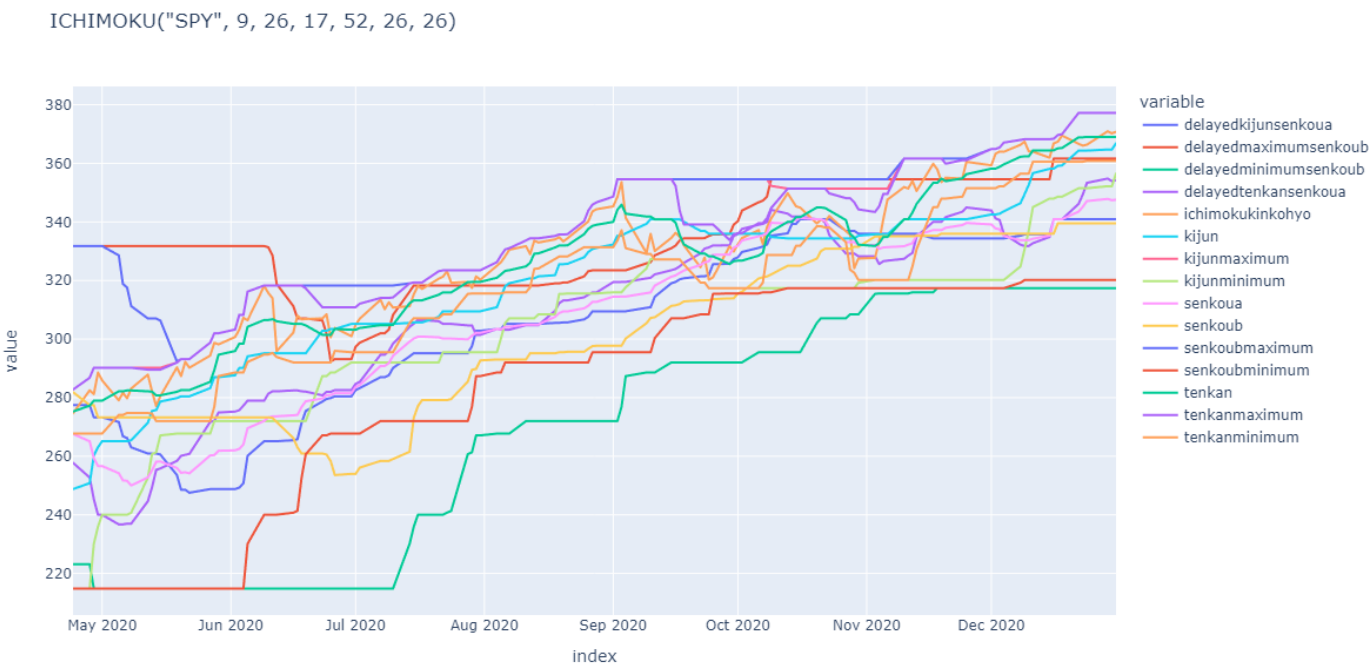
Return

`IchimokuKinkoHyo` - The new `IchimokuKinkoHyo` indicator object.

Definition at line 138 of file Indicators/IchimokuKinkoHyo.cs.

Visualization

The following image shows plot values of selected properties of `IchimokuKinkoHyo` using the plotly library.



Supported Indicators

Identity

Introduction

This indicator represents an indicator that is a ready after ingesting a single sample and always returns the same value as it is given.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using Identity Indicator

To create an automatic indicators for `Identity` , call the `Identity` helper method from the `QCAlgorithm` class. The `Identity` method creates a `Identity` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class IdentityAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.identity = self.Identity(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.identity.IsReady:
            # The current value of self.identity is represented by self.identity.Current.Value
            self.Plot("Identity", "identity", self.identity.Current.Value)
```

The following reference table describes the `Identity` method:

INDICATORS

Identity() 1/3

```
Identity QuantConnect.Algorithm.QCAlgorithm.Identity (
Symbol symbol,
*Func<IBaseData, Decimal> selector,
*String fieldName
)
```

Creates a new Identity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`Identity` - A new Identity indicator for the specified symbol and selector.

Definition at line 755 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

Identity() 2/3

```
Identity QuantConnect.Algorithm.QCAlgorithm.Identity (
Symbol symbol,
Resolution resolution,
*Func<IBaseData, Decimal> selector,
*String fieldName
)
```

Creates a new Identity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`Resolution`	resolution	The desired resolution of the data.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`Identity` - A new Identity indicator for the specified symbol and selector.

Definition at line 771 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

Identity() 3/3

```
Identity QuantConnect.Algorithm.QCAlgorithm.Identity (
Symbol symbol,
TimeSpan resolution,
*Func<IBaseData, Decimal> selector,
*String fieldName
)
```

Creates a new Identity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`TimeSpan`	resolution	The desired resolution of the data.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`Identity` - A new Identity indicator for the specified symbol and selector.

Definition at line 789 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Identity` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class IdentityAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.identity = Identity("SPY")

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.identity.Update(bar.EndTime, bar.Close)

        if self.identity.IsReady:
            # The current value of self.identity is represented by self.identity.Current.Value
            self.Plot("Identity", "identity", self.identity.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class IdentityAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.identity = Identity("SPY")
        self.RegisterIndicator(self.symbol, self.identity, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.identity.IsReady:
            # The current value of self.identity is represented by self.identity.Current.Value
            self.Plot("Identity", "identity", self.identity.Current.Value)
```

The following reference table describes the `Identity` constructor:

INDICATORS

Identity() 1/1

```
Identity QuantConnect.Indicators.Identity (
string name
)
```

Initializes a new instance of the Identity indicator with the specified name.

Show Details

Parameters		
`string`	name	The name of the indicator.

Return

`Identity` - The new `Identity` indicator object.

Definition at line 28 of file Indicators/Identity.cs.

Visualization

The following image shows plot values of selected properties of `Identity` using the plotly library.

Supported Indicators

Intraday Vwap

Introduction

Defines the canonical intraday VWAP indicator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VWAP Indicator

To create an automatic indicators for `IntradayVwap` , call the `VWAP` helper method from the `QCAlgorithm` class. The `VWAP` method creates a `IntradayVwap` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class IntradayVwapAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.vwap = self.VWAP(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.vwap.IsReady:
            # The current value of self.vwap is represented by self.vwap.Current.Value
            self.Plot("IntradayVwap", "vwap", self.vwap.Current.Value)
```

The following reference table describes the `VWAP` method:

INDICATORS

VWAP() 1/2

```
VolumeWeightedAveragePriceIndicator QuantConnect.Algorithm.QCAlgorithm.VWAP (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an VolumeWeightedAveragePrice (VWAP) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VWAP we want.
`Int32`	period	The period of the VWAP.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`VolumeWeightedAveragePriceIndicator` - The VolumeWeightedAveragePrice for the given parameters.

Definition at line 1831 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

VWAP() 2/2

```
IntradayVwap QuantConnect.Algorithm.QCAlgorithm.VWAP (
 Symbol symbol
)
```

Creates the canonical VWAP indicator that resets each day. The indicator will be automatically updated on the security's configured resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VWAP we want.

Return

`IntradayVwap` - The IntradayVWAP for the specified symbol.

Definition at line 1847 of file Algorithm/QCAlgorithm.Indicators.cs.

Kaufman Adaptive Moving Average

Introduction

This indicator computes the Kaufman Adaptive Moving Average (KAMA). The Kaufman Adaptive Moving Average is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:kaufman_s_adaptive_moving_average

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KAMA Indicator

To create an automatic indicators for `KaufmanAdaptiveMovingAverage` , call the `KAMA` helper method from the `QCAlgorithm` class. The `KAMA` method creates a `KaufmanAdaptiveMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class KaufmanAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kama = self.KAMA(self.symbol, 20, 10, 20)

    def OnData(self, slice: Slice) -> None:
        if self.kama.IsReady:
            # The current value of self.kama is represented by self.kama.Current.Value
            self.Plot("KaufmanAdaptiveMovingAverage", "kama", self.kama.Current.Value)
```

The following reference table describes the `KAMA` method:

INDICATORS

KAMA() 1/2

```
KaufmanAdaptiveMovingAverage QuantConnect.Algorithm.QCAlgorithm.KAMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new KaufmanAdaptiveMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose KAMA we want.
`Int32`	period	The period of the Efficiency Ratio (ER) of KAMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`KaufmanAdaptiveMovingAverage` - The KaufmanAdaptiveMovingAverage indicator for the requested symbol over the specified period.

Definition at line 806 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

KAMA() 2/2

```
KaufmanAdaptiveMovingAverage QuantConnect.Algorithm.QCAlgorithm.KAMA (
 Symbol symbol,
 Int32 period,
 Int32 fastEmaPeriod,
 Int32 slowEmaPeriod,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new KaufmanAdaptiveMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose KAMA we want.
`Int32`	period	The period of the Efficiency Ratio (ER).
`Int32`	fastEmaPeriod	The period of the fast EMA used to calculate the Smoothing Constant (SC).
`Int32`	slowEmaPeriod	The period of the slow EMA used to calculate the Smoothing Constant (SC).
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`KaufmanAdaptiveMovingAverage` - The KaufmanAdaptiveMovingAverage indicator for the requested symbol over the specified period.

Definition at line 822 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

class KaufmanAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kama = KaufmanAdaptiveMovingAverage(20, 10, 20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.kama.Update(bar.EndTime, bar.Close)

        if self.kama.IsReady:
            # The current value of self.kama is represented by self.kama.Current.Value
            self.Plot("KaufmanAdaptiveMovingAverage", "kama", self.kama.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class KaufmanAdaptiveMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kama = KaufmanAdaptiveMovingAverage(20, 10, 20)
        self.RegisterIndicator(self.symbol, self.kama, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.kama.IsReady:
            # The current value of self.kama is represented by self.kama.Current.Value
            self.Plot("KaufmanAdaptiveMovingAverage", "kama", self.kama.Current.Value)
```

The following reference table describes the `KaufmanAdaptiveMovingAverage` constructor:

INDICATORS

KaufmanAdaptiveMovingAverage() 1/2

```
KaufmanAdaptiveMovingAverage QuantConnect.Indicators.KaufmanAdaptiveMovingAverage (
string name,
int period,
*int fastEmaPeriod,
*int slowEmaPeriod
)
```

Initializes a new instance of the `KaufmanAdaptiveMovingAverag` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the Efficiency Ratio (ER).
`*int`	fastEmaPeriod	*(Optional) (Optional)* The period of the fast EMA used to calculate the Smoothing Constant (SC). Default: 2.
`*int`	slowEmaPeriod	*(Optional) (Optional)* The period of the slow EMA used to calculate the Smoothing Constant (SC). Default: 30.

Return

`KaufmanAdaptiveMovingAverage` - The new `KaufmanAdaptiveMovingAverage` indicator object.

Kaufman Efficiency Ratio

Introduction

This indicator computes the Kaufman Efficiency Ratio (KER). The Kaufman Efficiency Ratio is calculated as explained here: https://www.marketvolume.com/technicalanalysis/efficiencyratio.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KER Indicator

To create an automatic indicators for `KaufmanEfficiencyRatio` , call the `KER` helper method from the `QCAlgorithm` class. The `KER` method creates a `KaufmanEfficiencyRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
PY
class KaufmanEfficiencyRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ker = self.KER(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.ker.IsReady:
            # The current value of self.ker is represented by self.ker.Current.Value
            self.Plot("KaufmanEfficiencyRatio", "ker", self.ker.Current.Value)
```

The following reference table describes the `KER` method:

INDICATORS

KER() 1/1

```
KaufmanEfficiencyRatio QuantConnect.Algorithm.QCAlgorithm.KER (
Symbol symbol,
*Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates an KaufmanEfficiencyRatio indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose EF we want.
`*Int32`	period	*(Optional)* The period of the EF.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`KaufmanEfficiencyRatio` - The KaufmanEfficiencyRatio indicator for the given parameters.

Definition at line 841 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `KaufmanEfficiencyRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class KaufmanEfficiencyRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ker = KaufmanEfficiencyRatio(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.ker.Update(bar.EndTime, bar.Close)

        if self.ker.IsReady:
            # The current value of self.ker is represented by self.ker.Current.Value
            self.Plot("KaufmanEfficiencyRatio", "ker", self.ker.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class KaufmanEfficiencyRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ker = KaufmanEfficiencyRatio(20)
        self.RegisterIndicator(self.symbol, self.ker, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.ker.IsReady:
            # The current value of self.ker is represented by self.ker.Current.Value
            self.Plot("KaufmanEfficiencyRatio", "ker", self.ker.Current.Value)
```

The following reference table describes the `KaufmanEfficiencyRatio` constructor:

INDICATORS

KaufmanEfficiencyRatio() 1/2

```
KaufmanEfficiencyRatio QuantConnect.Indicators.KaufmanEfficiencyRatio (
string name,
int period
)
```

Initializes a new instance of the `KaufmanEfficiencyRati` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the Efficiency Ratio (ER).

Return

Keltner Channels

Introduction

This indicator creates a moving average (middle band) with an upper band and lower band fixed at k average True range multiples away from the middle band.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KCH Indicator

To create an automatic indicators for `KeltnerChannels` , call the `KCH` helper method from the `QCAlgorithm` class. The `KCH` method creates a `KeltnerChannels` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class KeltnerChannelsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kch = self.KCH(self.symbol, 20, 2, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.kch.IsReady:
            # The current value of self.kch is represented by self.kch.Current.Value
            self.Plot("KeltnerChannels", "kch", self.kch.Current.Value)
            # Plot all attributes of self.kch
            self.Plot("KeltnerChannels", "middleband", self.kch.MiddleBand.Current.Value)
            self.Plot("KeltnerChannels", "upperband", self.kch.UpperBand.Current.Value)
            self.Plot("KeltnerChannels", "lowerband", self.kch.LowerBand.Current.Value)
            self.Plot("KeltnerChannels", "averagetruerange", self.kch.AverageTrueRange.Current.Value)
```

The following reference table describes the `KCH` method:

INDICATORS

KCH() 1/1

```
KeltnerChannels QuantConnect.Algorithm.QCAlgorithm.KCH (
Symbol symbol,
Int32 period,
Decimal k,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Keltner Channels indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Keltner Channel we seek.
`Int32`	period	The period over which to compute the Keltner Channels.
`Decimal`	k	The number of multiples of the `AverageTrueRange` from the middle band of the Keltner Channels.
`*MovingAverageType`	movingAverageType	*(Optional)* Specifies the type of moving average to be used as the middle line of the Keltner Channel.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`KeltnerChannels` - The Keltner Channel indicator for the requested symbol.

Definition at line 862 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `KeltnerChannels` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```py
class KeltnerChannelsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kch = KeltnerChannels(20, 2, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.kch.Update(bar)

        if self.kch.IsReady:
            # The current value of self.kch is represented by self.kch.Current.Value
            self.Plot("KeltnerChannels", "kch", self.kch.Current.Value)
            # Plot all attributes of self.kch
            self.Plot("KeltnerChannels", "middleband", self.kch.MiddleBand.Current.Value)
            self.Plot("KeltnerChannels", "upperband", self.kch.UpperBand.Current.Value)
            self.Plot("KeltnerChannels", "lowerband", self.kch.LowerBand.Current.Value)
            self.Plot("KeltnerChannels", "averagetruerange", self.kch.AverageTrueRange.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class KeltnerChannelsAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.kch = KeltnerChannels(20, 2, MovingAverageType.Simple)
        self.RegisterIndicator(self.symbol, self.kch, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.kch.IsReady:
            # The current value of self.kch is represented by self.kch.Current.Value
            self.Plot("KeltnerChannels", "kch", self.kch.Current.Value)
            # Plot all attributes of self.kch
            self.Plot("KeltnerChannels", "middleband", self.kch.MiddleBand.Current.Value)
            self.Plot("KeltnerChannels", "upperband", self.kch.UpperBand.Current.Value)
            self.Plot("KeltnerChannels", "lowerband", self.kch.LowerBand.Current.Value)
            self.Plot("KeltnerChannels", "averagetruerange", self.kch.AverageTrueRange.Current.Value)
```

The following reference table describes the `KeltnerChannels` constructor:

INDICATORS

KeltnerChannels() 1/2

```
KeltnerChannels QuantConnect.Indicators.KeltnerChannels (
int period,
decimal k,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the KeltnerChannels class.

Show Details

Parameters		
int	period	The period of the average true range and moving average (middle band).
decimal	k	The number of multiplies specifying the distance between the middle band and upper or lower bands.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of moving average to be used. Default: MovingAverageType.Simple.

Return

`KeltnerChannels` - The new `KeltnerChannels` indicator object.

Definition at line 53 of file Indicators/KeltnerChannels.cs.

INDICATORS

KeltnerChannels() 2/2

```
KeltnerChannels QuantConnect.Indicators.KeltnerChannels (
string name,
int period,
decimal k,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the KeltnerChannels class.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the average true range and moving average (middle band).
decimal	k	The number of multiples specifying the distance between the middle band and upper or lower bands.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of moving average to be used. Default: MovingAverageType.Simple.

Return

`KeltnerChannels` - The new `KeltnerChannels` indicator object.

Definition at line 65 of file Indicators/KeltnerChannels.cs.

Least Squares Moving Average

Introduction

The Least Squares Moving Average (LSMA) first calculates a least squares regression line over the preceding time periods, and then projects it forward to the current period. In essence, it calculates what the value would be if the regression line continued. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LSMA Indicator

To create an automatic indicators for `LeastSquaresMovingAverage` , call the `LSMA` helper method from the `QCAlgorithm` class. The `LSMA` method creates a `LeastSquaresMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class LeastSquaresMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.lsma = self.LSMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.lsma.IsReady:
            # The current value of self.lsma is represented by self.lsma.Current.Value
            self.Plot("LeastSquaresMovingAverage", "lsma", self.lsma.Current.Value)
            # Plot all attributes of self.lsma
            self.Plot("LeastSquaresMovingAverage", "intercept", self.lsma.Intercept.Current.Value)
            self.Plot("LeastSquaresMovingAverage", "slope", self.lsma.Slope.Current.Value)
```

The following reference table describes the `LSMA` method:

INDICATORS

LSMA() 1/1

```
LeastSquaresMovingAverage QuantConnect.Algorithm.QCAlgorithm.LSMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates and registers a new Least Squares Moving Average instance.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose LSMA we seek.
`Int32`	period	The LSMA period. Normally 14.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`LeastSquaresMovingAverage` - A LeastSquaredMovingAverage configured with the specified period.

Definition at line 898 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `LeastSquaresMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class LeastSquaresMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.lsma = LeastSquaresMovingAverage(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.lsma.Update(bar.EndTime, bar.Close)

        if self.lsma.IsReady:
            # The current value of self.lsma is represented by self.lsma.Current.Value
            self.Plot("LeastSquaresMovingAverage", "lsma", self.lsma.Current.Value)
            # Plot all attributes of self.lsma
            self.Plot("LeastSquaresMovingAverage", "intercept", self.lsma.Intercept.Current.Value)
            self.Plot("LeastSquaresMovingAverage", "slope", self.lsma.Slope.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class LeastSquaresMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.lsma = LeastSquaresMovingAverage(20)
        self.RegisterIndicator(self.symbol, self.lsma, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.lsma.IsReady:
            # The current value of self.lsma is represented by self.lsma.Current.Value
            self.Plot("LeastSquaresMovingAverage", "lsma", self.lsma.Current.Value)
            # Plot all attributes of self.lsma
            self.Plot("LeastSquaresMovingAverage", "intercept", self.lsma.Intercept.Current.Value)
            self.Plot("LeastSquaresMovingAverage", "slope", self.lsma.Slope.Current.Value)
```

The following reference table describes the LeastSquaresMovingAverage constructor:

INDICATORS

LeastSquaresMovingAverage() 1/2

```
LeastSquaresMovingAverage QuantConnect.Indicators.LeastSquaresMovingAverage (
string name,
int period
)
```

Initializes a new instance of the LeastSquaresMovingAverag class.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The number of data points to hold in the window.

Return

LeastSquaresMovingAverage - The new LeastSquaresMovingAverage indicator object.

Supported Indicators

Linear Weighted Moving Average

Introduction

This indicator represents the traditional Weighted Moving Average indicator. The weight are linearly distributed according to the number of periods in the indicator. For example, a 4 period indicator will have a numerator of (4 * window[0]) + (3 * window[1]) + (2 * window[2]) + window[3] and a denominator of 4 + 3 + 2 + 1 = 10 During the warm up period, IsReady will return False, but the LWMA will still be computed correctly because the denominator will be the minimum of Samples factorial or Size factorial and the computation iterates over that minimum value. The RollingWindow of inputs is created when the indicator is created. A RollingWindow of LWMAs is not saved. That is up to the caller.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LWMA Indicator

To create an automatic indicators for `LinearWeightedMovingAverage` , call the `LWMA` helper method from the `QCAlgorithm` class. The `LWMA` method creates a `LinearWeightedMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class LinearWeightedMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.lwma = self.LWMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.lwma.IsReady:
            # The current value of self.lwma is represented by self.lwma.Current.Value
            self.Plot("LinearWeightedMovingAverage", "lwma", self.lwma.Current.Value)
```

The following reference table describes the `LWMA` method:

INDICATORS

LWMA() 1/1

```
LinearWeightedMovingAverage QuantConnect.Algorithm.QCAlgorithm.LWMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new LinearWeightedMovingAverage indicator. This indicator will linearly distribute the weights across the periods.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose LWMA we want.
`Int32`	period	The period over which to compute the LWMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`LinearWeightedMovingAverage` - The new `LinearWeightedMovingAverage` object.

Definition at line 917 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

Log Return

Introduction

This indicator represents the LogReturn indicator (LOGR) - log returns are useful for identifying price convergence/divergence in a given period - logr = log (current price / last price in period)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LOGR Indicator

To create an automatic indicators for `LogReturn` , call the `LOGR` helper method from the `QCAlgorithm` class. The `LOGR` method creates a `LogReturn` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class LogReturnAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.logr = self.LOGR(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.logr.IsReady:
            # The current value of self.logr is represented by self.logr.Current.Value
            self.Plot("LogReturn", "logr", self.logr.Current.Value)
```

The following reference table describes the `LOGR` method:

INDICATORS

LOGR() 1/1

```
LogReturn QuantConnect.Algorithm.QCAlgorithm.LOGR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new LogReturn indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose log return we seek.
`Int32`	period	The period of the log return.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`LogReturn` - log return indicator for the requested symbol.

Definition at line 880 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `LogReturn` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class LogReturnAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.logr = LogReturn(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.logr.Update(bar.EndTime, bar.Close)

        if self.logr.IsReady:
            # The current value of self.logr is represented by self.logr.Current.Value
            self.Plot("LogReturn", "logr", self.logr.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class LogReturnAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.logr = LogReturn(20)
        self.RegisterIndicator(self.symbol, self.logr, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.logr.IsReady:
            # The current value of self.logr is represented by self.logr.Current.Value
            self.Plot("LogReturn", "logr", self.logr.Current.Value)
```

The following reference table describes the `LogReturn` constructor:

INDICATORS

LogReturn() 1/2

```
LogReturn QuantConnect.Indicators.LogReturn (
string name,
int period
)
```

Initializes a new instance of the LogReturn class with the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the LOGR.

Return

`LogReturn` - The new `LogReturn` indicator object.

Definition at line 37 of file Indicators/LogReturn.cs.

INDICATORS

LogReturn() 2/2

```
LogReturn QuantConnect.Indicators.LogReturn (
int period
)
```

Initializes a new instance of the LogReturn class with the default name and period.

Show Details

Parameters		
`int`	period	The period of the SMA.

Return

`LogReturn` - The new `LogReturn` indicator object.

Supported Indicators

Mass Index

Introduction

The Mass Index uses the high-low range to identify trend reversals based on range expansions. In this sense, the Mass Index is a volatility indicator that does not have a directional bias. Instead, the Mass Index identifies range bulges that can foreshadow a reversal of the current trend. Developed by Donald Dorsey.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MASS Indicator

To create an automatic indicators for `MassIndex` , call the `MASS` helper method from the `QCAlgorithm` class. The `MASS` method creates a `MassIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class MassIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mass = self.MASS(self.symbol, 9, 25)

    def OnData(self, slice: Slice) -> None:
        if self.mass.IsReady:
            # The current value of self.mass is represented by self.mass.Current.Value
            self.Plot("MassIndex", "mass", self.mass.Current.Value)
```

The following reference table describes the `MASS` method:

INDICATORS

MASS() 1/1

```
MassIndex QuantConnect.Algorithm.QCAlgorithm.MASS (
 Symbol symbol,
 *Int32 emaPeriod,
 *Int32 sumPeriod,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates a new Mass Index indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Mass Index we want.
`*Int32`	emaPeriod	*(Optional)* The period used by both EMA.
`*Int32`	sumPeriod	*(Optional)* The sum period.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`MassIndex` - The Mass Index indicator for the requested symbol over the specified period.

Definition at line 1073 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `MassIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class MassIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mass = MassIndex(9, 25)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.mass.Update(bar)

        if self.mass.IsReady:
            # The current value of self.mass is represented by self.mass.Current.Value
            self.Plot("MassIndex", "mass", self.mass.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MassIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mass = MassIndex(9, 25)
        self.RegisterIndicator(self.symbol, self.mass, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.mass.IsReady:
            # The current value of self.mass is represented by self.mass.Current.Value
            self.Plot("MassIndex", "mass", self.mass.Current.Value)
```

The following reference table describes the `MassIndex` constructor:

INDICATORS

MassIndex() 1/2

```
MassIndex QuantConnect.Indicators.MassIndex (
string name,
int emaPeriod,
int sumPeriod
)
```

Initializes a new instance of the `MassInde` class.

Show Details

Parameters		
`string`	name	The name for this instance.
`int`	emaPeriod	The period used by both EMA.
`int`	sumPeriod	The sum period.

Return

`MassIndex` - The new `MassIndex` indicator object.

Definition at line 39 of file Indicators/MassIndex.cs.

INDICATORS

MassIndex() 2/2

```
MassIndex QuantConnect.Indicators.MassIndex (
*int emaPeriod,
*int sumPeriod
)
```

Initializes a new instance of the MassInde class.

Show Details

Parameters		
*int	emaPeriod	*(Optional) (Optional)* The period used by both EMA. Default: 9.
*int	sumPeriod	*(Optional) (Optional)* The sum period. Default: 25.

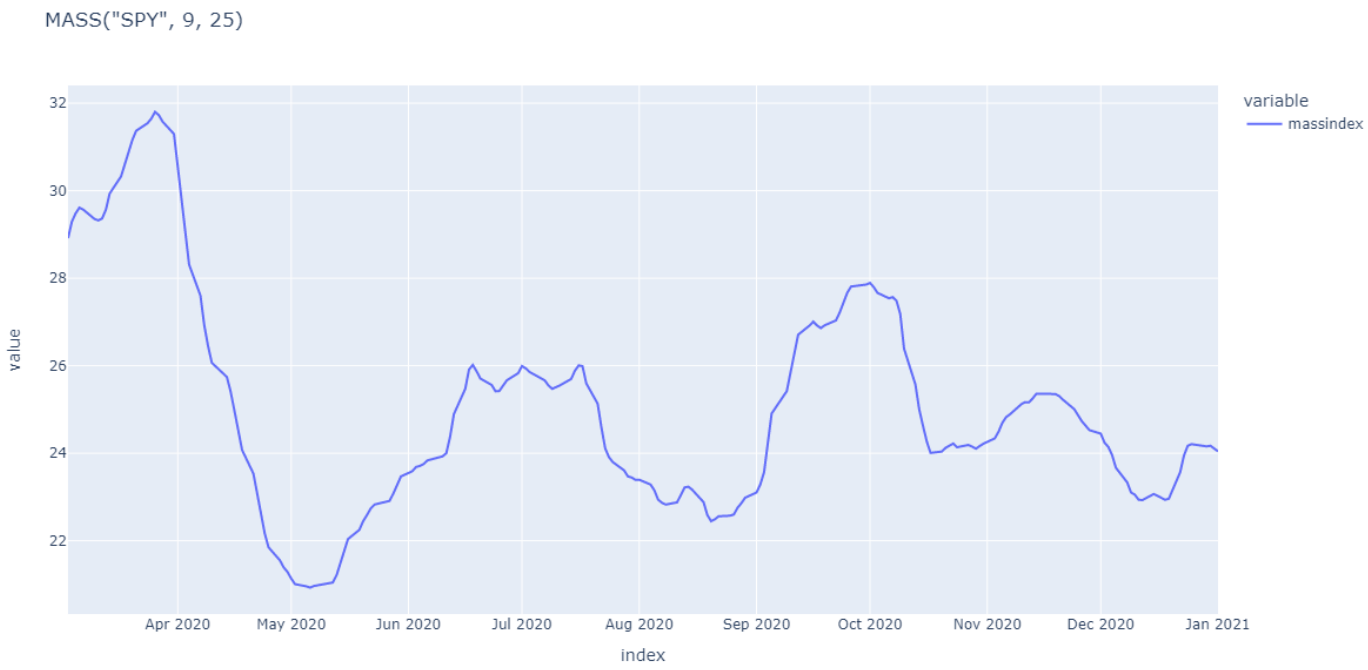
Return

MassIndex - The new MassIndex indicator object.

Definition at line 53 of file Indicators/MassIndex.cs.

Visualization

The following image shows plot values of selected properties of MassIndex using the plotly library.



Supported Indicators

Maximum

Introduction

This indicator represents an indicator capable of tracking the maximum value and how many periods ago it occurred

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MAX Indicator

To create an automatic indicators for `Maximum` , call the `MAX` helper method from the `QCAlgorithm` class. The `MAX` method creates a `Maximum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class MaximumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.max = self.MAX(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.max.IsReady:
            # The current value of self.max is represented by self.max.Current.Value
            self.Plot("Maximum", "max", self.max.Current.Value)
            # Plot all attributes of self.max
            self.Plot("Maximum", "periodssincemaximum", self.max.PeriodsSinceMaximum.Current.Value)
```

The following reference table describes the `MAX` method:

INDICATORS

MAX() 1/1

```
Maximum QuantConnect.Algorithm.QCAlgorithm.MAX (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Maximum indicator to compute the maximum value.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose max we want.
`Int32`	period	The look back period over which to compute the max value.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None and the symbol is of type TradeBar defaults to the High property, otherwise it defaults to Value property of BaseData (x => x.Value).

Return

`Maximum` - A Maximum indicator that compute the max value and the periods since the max value.

Definition at line 1017 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Maximum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class MaximumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.max = Maximum(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.max.Update(bar.EndTime, bar.Close)

        if self.max.IsReady:
            # The current value of self.max is represented by self.max.Current.Value
            self.Plot("Maximum", "max", self.max.Current.Value)
            # Plot all attributes of self.max
            self.Plot("Maximum", "periodssincemaximum", self.max.PeriodsSinceMaximum.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MaximumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.max = Maximum(20)
        self.RegisterIndicator(self.symbol, self.max, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.max.IsReady:
            # The current value of self.max is represented by self.max.Current.Value
            self.Plot("Maximum", "max", self.max.Current.Value)
            # Plot all attributes of self.max
            self.Plot("Maximum", "periodssincemaximum", self.max.PeriodsSinceMaximum.Current.Value)
```

The following reference table describes the `Maximum` constructor:

INDICATORS

Maximum() 1/2

```
Maximum QuantConnect.Indicators.Maximum (
int period
)
```

Creates a new Maximum indicator with the specified period.

Show Details

Parameters		
int	period	The period over which to look back.

Return

`Maximum` - The new `Maximum` indicator object.

Definition at line 44 of file Indicators/Maximum.cs.

INDICATORS

Maximum() 2/2

```
Maximum QuantConnect.Indicators.Maximum (
string name,
int period
)
```

Creates a new Maximum indicator with the specified period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period over which to look back.

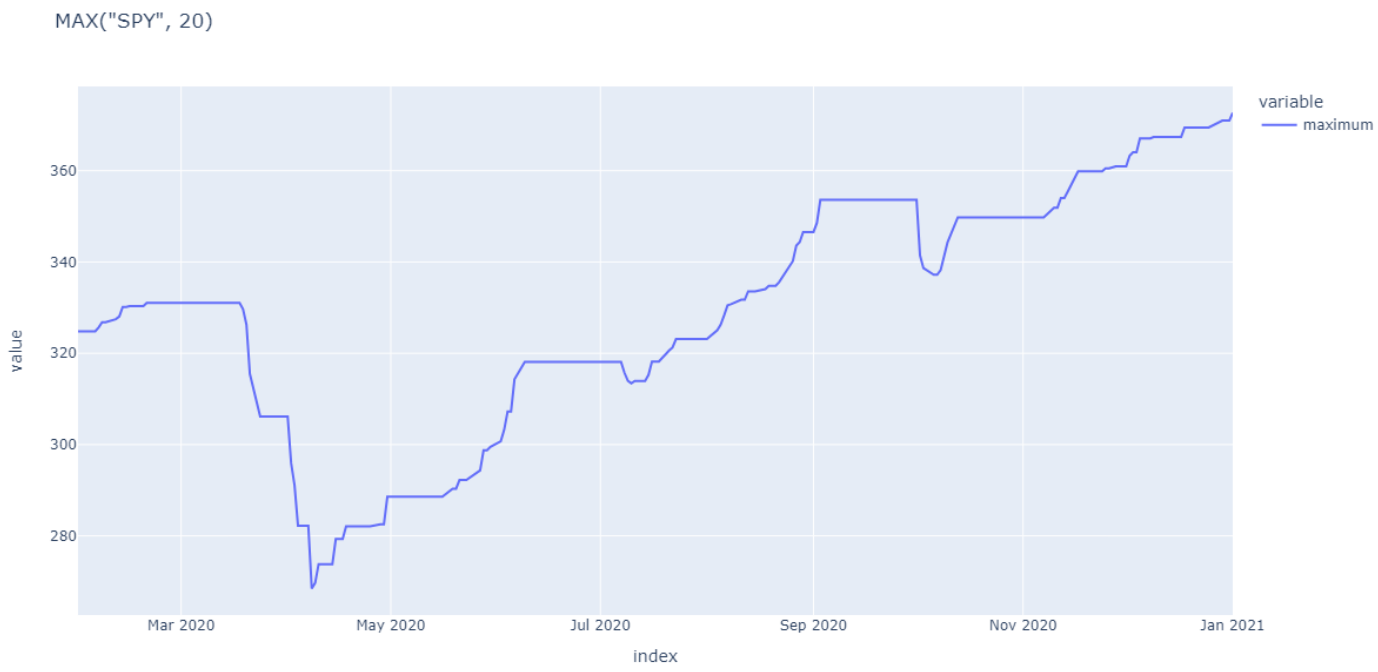
Return

`Maximum` - The new `Maximum` indicator object.

Definition at line 54 of file Indicators/Maximum.cs.

Visualization

The following image shows plot values of selected properties of `Maximum` using the plotly library.



Supported Indicators

Mc Clellan Oscillator

Introduction

The McClellan Oscillator is a market breadth indicator which was developed by Sherman and Marian McClellan. It is based on the difference between the number of advancing and declining periods.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOSC Indicator

To create an automatic indicators for `McClellanOscillator` , call the `MOSC` helper method from the `QCAlgorithm` class. The `MOSC` method creates a `McClellanOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class McClellanOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mosc = self.MOSC([self.symbol, Symbol.Create("QQQ", SecurityType.Equity, Market.USA)])

    def OnData(self, slice: Slice) -> None:
        if self.mosc.IsReady:
            # The current value of self.mosc is represented by self.mosc.Current.Value
            self.Plot("McClellanOscillator", "mosc", self.mosc.Current.Value)
            # Plot all attributes of self.mosc
            self.Plot("McClellanOscillator", "emafast", self.mosc.EMAFast.Current.Value)
            self.Plot("McClellanOscillator", "emaslow", self.mosc.EMASlow.Current.Value)
            self.Plot("McClellanOscillator", "addifference", self.mosc.ADDifference.Current.Value)
```

The following reference table describes the `MOSC` method:

INDICATORS

MOSC() 1/2

```
McClellanOscillator QuantConnect.Algorithm.QCAlgorithm.MOSC (
IEnumerable<Symbol> symbols,
*Int32 fastPeriod,
*Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new McClellan Oscillator indicator.

Show Details

Parameters		
`IEnumerable<Symbol>`	symbols	/
`*Int32`	fastPeriod	*(Optional)* /
`*Int32`	slowPeriod	*(Optional)* /
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* /

Return

`McClellanOscillator` - The new `McClellanOscillator` object.

Definition at line 2044 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MOSC() 2/2

```
McClellanOscillator QuantConnect.Algorithm.QCAlgorithm.MOSC (
Symbol> symbols,
*Int32 fastPeriod,
*Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new McClellan Oscillator indicator.

Show Details

Parameters		
`Symbol>`	symbols	The symbols whose McClellan Oscillator we want.
`*Int32`	fastPeriod	*(Optional)* Fast period EMA of advance decline difference.
`*Int32`	slowPeriod	*(Optional)* Slow period EMA of advance decline difference.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`McClellanOscillator` - The McClellan Oscillator indicator for the requested symbol over the specified period.

Definition at line 2059 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `McClellanOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class McClellanOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mosc = McClellanOscillator("")

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.mosc.Update(bar)

        if self.mosc.IsReady:
            # The current value of self.mosc is represented by self.mosc.Current.Value
            self.Plot("McClellanOscillator", "mosc", self.mosc.Current.Value)
            # Plot all attributes of self.mosc
            self.Plot("McClellanOscillator", "emafast", self.mosc.EMAFast.Current.Value)
            self.Plot("McClellanOscillator", "emaslow", self.mosc.EMASlow.Current.Value)
            self.Plot("McClellanOscillator", "addifference", self.mosc.ADDifference.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class McClellanOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mosc = McClellanOscillator("")
        self.RegisterIndicator(self.symbol, self.mosc, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.mosc.IsReady:
            # The current value of self.mosc is represented by self.mosc.Current.Value
            self.Plot("McClellanOscillator", "mosc", self.mosc.Current.Value)
            # Plot all attributes of self.mosc
            self.Plot("McClellanOscillator", "emafast", self.mosc.EMAFast.Current.Value)
            self.Plot("McClellanOscillator", "emaslow", self.mosc.EMASlow.Current.Value)
            self.Plot("McClellanOscillator", "addifference", self.mosc.ADDifference.Current.Value)
```

The following reference table describes the `McClellanOscillator` constructor:

INDICATORS

McClellanOscillator() 1/2

```
McClellanOscillator QuantConnect.Indicators.McClellanOscillator (
string name,
*int fastPeriod,
*int slowPeriod
)
```

The slow period of EMA of advance decline difference.

Show Details

Parameters		
`string`	name	The name of the indicator.
`*int`	fastPeriod	*(Optional) (Optional)* The fast period of EMA of advance decline difference. Default: 19.
`*int`	slowPeriod	*(Optional) (Optional)* The slow period of EMA of advance decline difference. Default: 39.

Return

`McClellanOscillator` - The new `McClellanOscillator` indicator object.

Definition at line 61 of file Indicators/McClellanOscillator.cs.

INDICATORS

McClellanOscillator() 2/2

```
McClellanOscillator QuantConnect.Indicators.McClellanOscillator (
*int fastPeriod,
*int slowPeriod
)
```

The slow period of EMA of advance decline difference.

Mc Clellan Summation Index

Introduction

The McClellan Summation Index (MSI) is a market breadth indicator that is based on the rolling average of difference between the number of advancing and declining issues on a stock exchange. It is generally considered as is a long-term version of the

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MSI Indicator

To create an automatic indicators for `McClellanSummationIndex` , call the `MSI` helper method from the `QCAlgorithm` class. The `MSI` method creates a `McClellanSummationIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class McClellanSummationIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.msi = self.MSI([self.symbol, Symbol.Create("QQQ", SecurityType.Equity, Market.USA)])

    def OnData(self, slice: Slice) -> None:
        if self.msi.IsReady:
            # The current value of self.msi is represented by self.msi.Current.Value
            self.Plot("McClellanSummationIndex", "msi", self.msi.Current.Value)
            # Plot all attributes of self.msi
            self.Plot("McClellanSummationIndex", "mcclellanoscillator",
self.msi.McClellanOscillator.Current.Value)
```

The following reference table describes the `MSI` method:

INDICATORS

MSI() 1/2

```
McClellanSummationIndex QuantConnect.Algorithm.QCAlgorithm.MSI (
IEnumerable<Symbol> symbols,
*Int32 fastPeriod,
*Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new McClellan Summation Index indicator.

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
*Int32	fastPeriod	*(Optional)* /
*Int32	slowPeriod	*(Optional)* /
*Nullable<Resolution>	resolution	*(Optional)* /
*Func<IBaseData, TradeBar>	selector	*(Optional)* /

Return

`McClellanSummationIndex` - The new `McClellanSummationIndex` object.

Definition at line 2082 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MSI() 2/2

```
McClellanSummationIndex QuantConnect.Algorithm.QCAlgorithm.MSI (
Symbol> symbols,
*Int32 fastPeriod,
*Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new McClellan Summation Index indicator.

Show Details

Parameters		
`Symbol>`	symbols	The symbols whose McClellan Summation Index we want.
`*Int32`	fastPeriod	*(Optional)* Fast period EMA of advance decline difference.
`*Int32`	slowPeriod	*(Optional)* Slow period EMA of advance decline difference.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`McClellanSummationIndex` - The McClellan Summation Index indicator for the requested symbol over the specified period.

Definition at line 2097 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `McClellanSummationIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class McClellanSummationIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.msi = McClellanSummationIndex("")

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.msi.Update(bar)

        if self.msi.IsReady:
            # The current value of self.msi is represented by self.msi.Current.Value
            self.Plot("McClellanSummationIndex", "msi", self.msi.Current.Value)
            # Plot all attributes of self.msi
            self.Plot("McClellanSummationIndex", "mcclellanoscillator",
self.msi.McClellanOscillator.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class McClellanSummationIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.msi = McClellanSummationIndex("")
        self.RegisterIndicator(self.symbol, self.msi, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.msi.IsReady:
            # The current value of self.msi is represented by self.msi.Current.Value
            self.Plot("McClellanSummationIndex", "msi", self.msi.Current.Value)
            # Plot all attributes of self.msi
            self.Plot("McClellanSummationIndex", "mcclellanoscillator",
self.msi.McClellanOscillator.Current.Value)
```

The following reference table describes the `McClellanSummationIndex` constructor:

INDICATORS

McClellanSummationIndex() 1/2

```
McClellanSummationIndex QuantConnect.Indicators.McClellanSummationIndex (
string name,
*int fastPeriod,
*int slowPeriod
)
```

The slow period of EMA of advance decline difference.

Show Details

Parameters		
`string`	name	The name of the indicator.
`*int`	fastPeriod	*(Optional) (Optional)* The fast period of EMA of advance decline difference. Default: 19.
`*int`	slowPeriod	*(Optional) (Optional)* The slow period of EMA of advance decline difference. Default: 39.

Return

`McClellanSummationIndex` - The new `McClellanSummationIndex` indicator object.

Mean Absolute Deviation

Introduction

This indicator computes the n-period mean absolute deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MAD Indicator

To create an automatic indicators for `MeanAbsoluteDeviation` , call the `MAD` helper method from the `QCAlgorithm` class. The `MAD` method creates a `MeanAbsoluteDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class MeanAbsoluteDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mad = self.MAD(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.mad.IsReady:
            # The current value of self.mad is represented by self.mad.Current.Value
            self.Plot("MeanAbsoluteDeviation", "mad", self.mad.Current.Value)
            # Plot all attributes of self.mad
            self.Plot("MeanAbsoluteDeviation", "mad", self.mad.Mean.Current.Value)
```

The following reference table describes the `MAD` method:

INDICATORS

MAD() 1/1

```
MeanAbsoluteDeviation QuantConnect.Algorithm.QCAlgorithm.MAD (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new MeanAbsoluteDeviation indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MeanAbsoluteDeviation we want.
`Int32`	period	The period over which to compute the MeanAbsoluteDeviation.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MeanAbsoluteDeviation` - The MeanAbsoluteDeviation indicator for the requested symbol over the specified period.

Definition at line 956 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `MeanAbsoluteDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class MeanAbsoluteDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mad = MeanAbsoluteDeviation(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.mad.Update(bar.EndTime, bar.Close)

        if self.mad.IsReady:
            # The current value of self.mad is represented by self.mad.Current.Value
            self.Plot("MeanAbsoluteDeviation", "mad", self.mad.Current.Value)
            # Plot all attributes of self.mad
            self.Plot("MeanAbsoluteDeviation", "mean", self.mad.Mean.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MeanAbsoluteDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mad = MeanAbsoluteDeviation(20)
        self.RegisterIndicator(self.symbol, self.mad, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.mad.IsReady:
            # The current value of self.mad is represented by self.mad.Current.Value
            self.Plot("MeanAbsoluteDeviation", "mad", self.mad.Current.Value)
            # Plot all attributes of self.mad
            self.Plot("MeanAbsoluteDeviation", "mean", self.mad.Mean.Current.Value)
```

The following reference table describes the `MeanAbsoluteDeviation` constructor:

INDICATORS

MeanAbsoluteDeviation() 1/2

```
MeanAbsoluteDeviation QuantConnect.Indicators.MeanAbsoluteDeviation (
int period
)
```

Evaluates the mean absolute deviation of samples in the lookback period.

Show Details

Parameters		
int	period	The sample size of the standard deviation.

Return

`MeanAbsoluteDeviation` - The new `MeanAbsoluteDeviation` indicator object.

Definition at line 37 of file Indicators/MeanAbsoluteDeviation.cs.

INDICATORS

MeanAbsoluteDeviation() 2/2

```
MeanAbsoluteDeviation QuantConnect.Indicators.MeanAbsoluteDeviation (
string name,
int period
)
```

Evaluates the mean absolute deviation of samples in the look-back period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The sample size of the mean absolute deviation.

Return

`MeanAbsoluteDeviation` - The new `MeanAbsoluteDeviation` indicator object.

Definition at line 49 of file Indicators/MeanAbsoluteDeviation.cs.

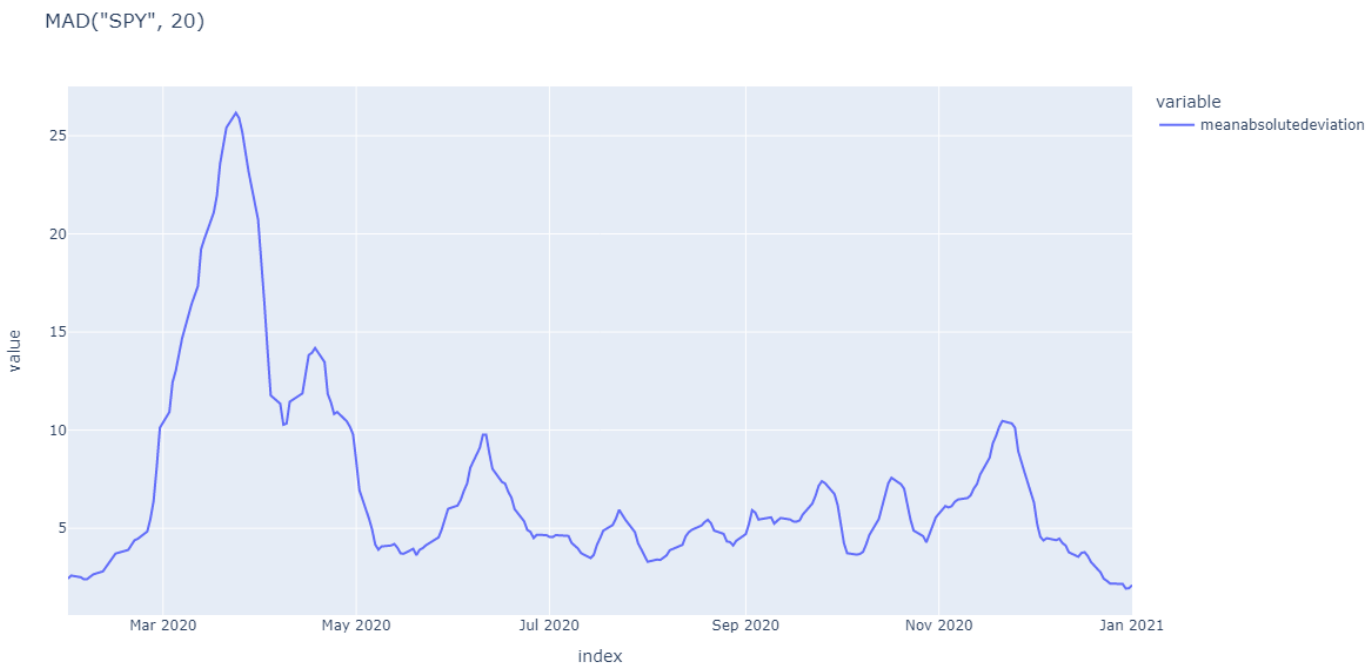
The following image shows plot values of selected properties of `MeanAbsoluteDeviation` using the plotly library.



Supported Indicators

Mid Point

Introduction

This indicator computes the MidPoint (MIDPOINT) The MidPoint is calculated using the following formula: MIDPOINT = (Highest Value + Lowest Value) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIDPOINT Indicator

To create an automatic indicators for `MidPoint` , call the `MIDPOINT` helper method from the `QCAlgorithm` class. The `MIDPOINT` method creates a `MidPoint` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class MidPointAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.midpoint = self.MIDPOINT(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.midpoint.IsReady:
            # The current value of self.midpoint is represented by self.midpoint.Current.Value
            self.Plot("MidPoint", "midpoint", self.midpoint.Current.Value)
```

The following reference table describes the `MIDPOINT` method:

INDICATORS

MIDPOINT() 1/1

```
MidPoint QuantConnect.Algorithm.QCAlgorithm.MIDPOINT (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new MidPoint indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MIDPOINT we want.
`Int32`	period	The period over which to compute the MIDPOINT.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MidPoint` - The MidPoint indicator for the requested symbol over the specified period.

Definition at line 1091 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `MidPoint` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```
PY
class MidPointAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.midpoint = MidPoint(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.midpoint.Update(bar.EndTime, bar.Close)

        if self.midpoint.IsReady:
            # The current value of self.midpoint is represented by self.midpoint.Current.Value
            self.Plot("MidPoint", "midpoint", self.midpoint.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MidPointAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.midpoint = MidPoint(20)
        self.RegisterIndicator(self.symbol, self.midpoint, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.midpoint.IsReady:
            # The current value of self.midpoint is represented by self.midpoint.Current.Value
            self.Plot("MidPoint", "midpoint", self.midpoint.Current.Value)
```

The following reference table describes the `MidPoint` constructor:

INDICATORS

MidPoint() 1/2

```
MidPoint QuantConnect.Indicators.MidPoint (
string name,
int period
)
```

Initializes a new instance of the `MidPoin` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the MIDPOINT.

Return

`MidPoint` - The new `MidPoint` indicator object.

Definition at line 34 of file Indicators/MidPoint.cs.

INDICATORS

MidPoint() 2/2

```
MidPoint QuantConnect.Indicators.MidPoint (
int period
)
```

Initializes a new instance of the `MidPoin` class using the specified period.

Show Details

Parameters		
`int`	period	The period of the MIDPOINT.

Return

`MidPoint` - The new `MidPoint` indicator object.

Mid Price

Introduction

This indicator computes the MidPrice (MIDPRICE). The MidPrice is calculated using the following formula: MIDPRICE = (Highest High + Lowest Low) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIDPRICE Indicator

To create an automatic indicators for `MidPrice` , call the `MIDPRICE` helper method from the `QCAlgorithm` class. The `MIDPRICE` method creates a `MidPrice` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class MidPriceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.midprice = self.MIDPRICE(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.midprice.IsReady:
            # The current value of self.midprice is represented by self.midprice.Current.Value
            self.Plot("MidPrice", "midprice", self.midprice.Current.Value)
```

The following reference table describes the `MIDPRICE` method:

INDICATORS

MIDPRICE() 1/1

```
MidPrice QuantConnect.Algorithm.QCAlgorithm.MIDPRICE (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new MidPrice indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MIDPRICE we want.
`Int32`	period	The period over which to compute the MIDPRICE.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`MidPrice` - The MidPrice indicator for the requested symbol over the specified period.

Definition at line 1109 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `MidPrice` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class MidPriceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.midprice = MidPrice(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.midprice.Update(bar)

        if self.midprice.IsReady:
            # The current value of self.midprice is represented by self.midprice.Current.Value
            self.Plot("MidPrice", "midprice", self.midprice.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MidPriceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.midprice = MidPrice(20)
        self.RegisterIndicator(self.symbol, self.midprice, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.midprice.IsReady:
            # The current value of self.midprice is represented by self.midprice.Current.Value
            self.Plot("MidPrice", "midprice", self.midprice.Current.Value)
```

The following reference table describes the `MidPrice` constructor:

INDICATORS

MidPrice() 1/2

```
MidPrice QuantConnect.Indicators.MidPrice (
string name,
int period
)
```

Initializes a new instance of the `MidPric` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the MIDPRICE.

Return

`MidPrice` - The new `MidPrice` indicator object.

Definition at line 36 of file Indicators/MidPrice.cs.

INDICATORS

MidPrice() 2/2

```
MidPrice QuantConnect.Indicators.MidPrice (
int period
)
```

Initializes a new instance of the `MidPric` class using the specified period.

Show Details

Parameters		
`int`	period	The period of the MIDPRICE.

Return

`MidPrice` - The new `MidPrice` indicator object.

Supported Indicators

Minimum

Introduction

This indicator represents an indicator capable of tracking the minimum value and how many periods ago it occurred

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIN Indicator

To create an automatic indicators for `Minimum` , call the `MIN` helper method from the `QCAlgorithm` class. The `MIN` method creates a `Minimum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class MinimumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.min = self.MIN(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.min.IsReady:
            # The current value of self.min is represented by self.min.Current.Value
            self.Plot("Minimum", "min", self.min.Current.Value)
            # Plot all attributes of self.min
            self.Plot("Minimum", "periodssinceminimum", self.min.PeriodsSinceMinimum.Current.Value)
```

The following reference table describes the `MIN` method:

INDICATORS

MIN() 1/1

```
Minimum QuantConnect.Algorithm.QCAlgorithm.MIN (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new Minimum indicator to compute the minimum value.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose min we want.
`Int32`	period	The look back period over which to compute the min value.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None and the symbol is of type TradeBar defaults to the Low property, otherwise it defaults to Value property of BaseData (x => x.Value).

Return

`Minimum` - A Minimum indicator that compute the in value and the periods since the min value.

Definition at line 1128 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Minimum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class MinimumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.min = Minimum(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.min.Update(bar.EndTime, bar.Close)

        if self.min.IsReady:
            # The current value of self.min is represented by self.min.Current.Value
            self.Plot("Minimum", "min", self.min.Current.Value)
            # Plot all attributes of self.min
            self.Plot("Minimum", "periodssinceminimum", self.min.PeriodsSinceMinimum.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MinimumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.min = Minimum(20)
        self.RegisterIndicator(self.symbol, self.min, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.min.IsReady:
            # The current value of self.min is represented by self.min.Current.Value
            self.Plot("Minimum", "min", self.min.Current.Value)
            # Plot all attributes of self.min
            self.Plot("Minimum", "periodssinceminimum", self.min.PeriodsSinceMinimum.Current.Value)
```

The following reference table describes the `Minimum` constructor:

INDICATORS

Minimum() 1/2

```
Minimum QuantConnect.Indicators.Minimum (
int period
)
```

Creates a new Minimum indicator with the specified period.

Show Details

Parameters		
int	period	The period over which to look back.

Momentum

Introduction

This indicator computes the n-period change in a value using the following: value_0 - value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOM Indicator

To create an automatic indicators for `Momentum` , call the `MOM` helper method from the `QCAlgorithm` class. The `MOM` method creates a `Momentum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class MomentumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mom = self.MOM(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.mom.IsReady:
            # The current value of self.mom is represented by self.mom.Current.Value
            self.Plot("Momentum", "mom", self.mom.Current.Value)
```

The following reference table describes the `MOM` method:

INDICATORS

MOM() 1/1

```
Momentum QuantConnect.Algorithm.QCAlgorithm.MOM (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Momentum indicator. This will compute the absolute n-period change in the security. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose momentum we want.
`Int32`	period	The period over which to compute the momentum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`Momentum` - The momentum indicator for the requested symbol over the specified period.

Definition at line 1164 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Momentum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class MomentumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mom = Momentum(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.mom.Update(bar.EndTime, bar.Close)

        if self.mom.IsReady:
            # The current value of self.mom is represented by self.mom.Current.Value
            self.Plot("Momentum", "mom", self.mom.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class MomentumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mom = Momentum(20)
        self.RegisterIndicator(self.symbol, self.mom, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:

Momentum Percent

Introduction

This indicator computes the n-period percentage rate of change in a value using the following: 100 * (value_0 - value_n) / value_n This indicator yields the same results of RateOfChangePercent

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOMP Indicator

To create an automatic indicators for `MomentumPercent` , call the `MOMP` helper method from the `QCAlgorithm` class. The `MOMP` method creates a `MomentumPercent` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class MomentumPercentAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.momp = self.MOMP(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.momp.IsReady:
            # The current value of self.momp is represented by self.momp.Current.Value
            self.Plot("MomentumPercent", "momp", self.momp.Current.Value)
```

The following reference table describes the `MOMP` method:

INDICATORS

MOMP() 1/1

```
MomentumPercent QuantConnect.Algorithm.QCAlgorithm.MOMP (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new MomentumPercent indicator. This will compute the n-period percent change in the security. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose momentum we want.
`Int32`	period	The period over which to compute the momentum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MomentumPercent` - The momentum indicator for the requested symbol over the specified period.

Definition at line 1202 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

The following reference table describes the `MomentumPercent` constructor:

INDICATORS

MomentumPercent() 1/2

```
MomentumPercent QuantConnect.Indicators.MomentumPercent (
int period
)
```

Creates a new MomentumPercent indicator with the specified period.

Show Details

Parameters		
int	period	The period over which to perform to computation.

Return

`MomentumPercent` - The new `MomentumPercent` indicator object.

Definition at line 30 of file Indicators/MomentumPercent.cs.

INDICATORS

MomentumPercent() 2/2

```
MomentumPercent QuantConnect.Indicators.MomentumPercent (
string name,
int period
)
```

Creates a new MomentumPercent indicator with the specified period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period over which to perform to computation.

Return

`MomentumPercent` - The new `MomentumPercent` indicator object.

Definition at line 40 of file Indicators/MomentumPercent.cs.

Supported Indicators

Momersion Indicator

Introduction

Oscillator indicator that measures momentum and mean-reversion over a specified period n. source Harris, Michael. "Momersion Indicator." Price Action Lab., 13 Aug. 2015. Web.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOMERSION Indicator

To create an automatic indicators for `MomersionIndicator` , call the `MOMERSION` helper method from the `QCAlgorithm` class. The `MOMERSION` method creates a `MomersionIndicator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class MomersionIndicatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.momersion = self.MOMERSION(self.symbol, 10, 20)

    def OnData(self, slice: Slice) -> None:
        if self.momersion.IsReady:
            # The current value of self.momersion is represented by self.momersion.Current.Value
            self.Plot("MomersionIndicator", "momersion", self.momersion.Current.Value)
```

The following reference table describes the `MOMERSION` method:

INDICATORS

MOMERSION() 1/1

```
MomersionIndicator QuantConnect.Algorithm.QCAlgorithm.MOMERSION (
Symbol symbol,
Nullable<Int32> minPeriod,
Int32 fullPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Momersion indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Momersion we want.
`Nullable<Int32>`	minPeriod	The minimum period over which to compute the Momersion. Must be greater than 3. If None, only full period will be used in computations.
`Int32`	fullPeriod	The full period over which to compute the Momersion.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MomersionIndicator` - The Momersion indicator for the requested symbol over the specified period.

Definition at line 1183 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `MomersionIndicator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class MomersionIndicatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.momersion = MomersionIndicator(10, 20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.momersion.Update(bar.EndTime, bar.Close)

        if self.momersion.IsReady:
            # The current value of self.momersion is represented by self.momersion.Current.Value
            self.Plot("MomersionIndicator", "momersion", self.momersion.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MomersionIndicatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.momersion = MomersionIndicator(10, 20)
        self.RegisterIndicator(self.symbol, self.momersion, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.momersion.IsReady:
            # The current value of self.momersion is represented by self.momersion.Current.Value
            self.Plot("MomersionIndicator", "momersion", self.momersion.Current.Value)
```

The following reference table describes the `MomersionIndicator` constructor:

INDICATORS

MomersionIndicator() 1/3

```
MomersionIndicator QuantConnect.Indicators.MomersionIndicator (
string name,
int? minPeriod,
int fullPeriod
)
```

Initializes a new instance of the `MomersionIndicato` class.

Show Details

Parameters		
`string`	name	The name.
`int?`	minPeriod	The minimum period.
`int`	fullPeriod	The full period.

Return

`MomersionIndicator` - The new `MomersionIndicator` indicator object.

Definition at line 48 of file Indicators/Momersion.cs.

INDICATORS

MomersionIndicator() 2/3

```
MomersionIndicator QuantConnect.Indicators.MomersionIndicator (
int? minPeriod,
int fullPeriod
)
```

Initializes a new instance of the MomersionIndicato class.

Show Details

Parameters		
int?	minPeriod	The minimum period.
int	fullPeriod	The full period.

Return

MomersionIndicator - The new MomersionIndicator indicator object.

Definition at line 65 of file Indicators/Momersion.cs.

INDICATORS

MomersionIndicator() 3/3

```
MomersionIndicator QuantConnect.Indicators.MomersionIndicator (
int fullPeriod
)
```

Initializes a new instance of the MomersionIndicato class.

Show Details

Parameters		
int	fullPeriod	The full period.

Return

MomersionIndicator - The new MomersionIndicator indicator object.

Money Flow Index

Introduction

The Money Flow Index (MFI) is an oscillator that uses both price and volume to measure buying and selling pressure Typical Price = (High + Low + Close)/3 Money Flow = Typical Price x Volume Positive Money Flow = Sum of the money flows of all days where the typical price is greater than the previous day's typical price Negative Money Flow = Sum of the money flows of all days where the typical price is less than the previous day's typical price Money Flow Ratio = (14-period Positive Money Flow)/(14-period Negative Money Flow) Money Flow Index = 100 x Positive Money Flow / (Positive Money Flow + Negative Money Flow)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MFI Indicator

To create an automatic indicators for `MoneyFlowIndex` , call the `MFI` helper method from the `QCAlgorithm` class. The `MFI` method creates a `MoneyFlowIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class MoneyFlowIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mfi = self.MFI(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.mfi.IsReady:
            # The current value of self.mfi is represented by self.mfi.Current.Value
            self.Plot("MoneyFlowIndex", "mfi", self.mfi.Current.Value)
            # Plot all attributes of self.mfi
            self.Plot("MoneyFlowIndex", "positivemoneyflow", self.mfi.PositiveMoneyFlow.Current.Value)
            self.Plot("MoneyFlowIndex", "negativemoneyflow", self.mfi.NegativeMoneyFlow.Current.Value)
            self.Plot("MoneyFlowIndex", "previoustypicalprice",
self.mfi.PreviousTypicalPrice.Current.Value)
```

The following reference table describes the `MFI` method:

INDICATORS

MFI() 1/1

```
MoneyFlowIndex QuantConnect.Algorithm.QCAlgorithm.MFI (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new MoneyFlowIndex indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MFI we want.
`Int32`	period	The period over which to compute the MFI.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`MoneyFlowIndex` - The MoneyFlowIndex indicator for the requested symbol over the specified period.

Definition at line 1053 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `MoneyFlowIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

```py
class MoneyFlowIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mfi = MoneyFlowIndex(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.mfi.Update(bar)

        if self.mfi.IsReady:
            # The current value of self.mfi is represented by self.mfi.Current.Value
            self.Plot("MoneyFlowIndex", "mfi", self.mfi.Current.Value)
            # Plot all attributes of self.mfi
            self.Plot("MoneyFlowIndex", "positivemoneyflow", self.mfi.PositiveMoneyFlow.Current.Value)
            self.Plot("MoneyFlowIndex", "negativemoneyflow", self.mfi.NegativeMoneyFlow.Current.Value)
            self.Plot("MoneyFlowIndex", "previoustypicalprice",
self.mfi.PreviousTypicalPrice.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MoneyFlowIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.mfi = MoneyFlowIndex(20)
        self.RegisterIndicator(self.symbol, self.mfi, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.mfi.IsReady:
            # The current value of self.mfi is represented by self.mfi.Current.Value
            self.Plot("MoneyFlowIndex", "mfi", self.mfi.Current.Value)
            # Plot all attributes of self.mfi
            self.Plot("MoneyFlowIndex", "positivemoneyflow", self.mfi.PositiveMoneyFlow.Current.Value)
            self.Plot("MoneyFlowIndex", "negativemoneyflow", self.mfi.NegativeMoneyFlow.Current.Value)
            self.Plot("MoneyFlowIndex", "previoustypicalprice",
self.mfi.PreviousTypicalPrice.Current.Value)
```

The following reference table describes the `MoneyFlowIndex` constructor:

INDICATORS

MoneyFlowIndex() 1/2

```
MoneyFlowIndex QuantConnect.Indicators.MoneyFlowIndex (
int period
)
```

Initializes a new instance of the MoneyFlowIndex class.

Show Details

Moving Average Convergence Divergence

Introduction

This indicator creates two moving averages defined on a base indicator and produces the difference between the fast and slow averages.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MACD Indicator

To create an automatic indicators for `MovingAverageConvergenceDivergence` , call the `MACD` helper method from the `QCAlgorithm` class. The `MACD` method creates a `MovingAverageConvergenceDivergence` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
class MovingAverageConvergenceDivergenceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.macd = self.MACD(self.symbol, 12, 26, 9, MovingAverageType.Exponential)

    def OnData(self, slice: Slice) -> None:
        if self.macd.IsReady:
            # The current value of self.macd is represented by self.macd.Current.Value
            self.Plot("MovingAverageConvergenceDivergence", "macd", self.macd.Current.Value)
            # Plot all attributes of self.macd
            self.Plot("MovingAverageConvergenceDivergence", "fast", self.macd.Fast.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "slow", self.macd.Slow.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "signal", self.macd.Signal.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "histogram",
self.macd.Histogram.Current.Value)
```

The following reference table describes the `MACD` method:

INDICATORS

MACD() 1/1

```
MovingAverageConvergenceDivergence QuantConnect.Algorithm.QCAlgorithm.MACD (
 Symbol symbol,
 Int32 fastPeriod,
 Int32 slowPeriod,
 Int32 signalPeriod,
 *MovingAverageType type,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a MACD indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MACD we want.
`Int32`	fastPeriod	The period for the fast moving average.
`Int32`	slowPeriod	The period for the slow moving average.
`Int32`	signalPeriod	The period for the signal moving average.
`*MovingAverageType`	type	*(Optional)* The type of moving average to use for the MACD.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MovingAverageConvergenceDivergence` - The moving average convergence divergence between the fast and slow averages.

Definition at line 938 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `MovingAverageConvergenceDivergence` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class MovingAverageConvergenceDivergenceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.macd = MovingAverageConvergenceDivergence(12, 26, 9, MovingAverageType.Exponential)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.macd.Update(bar.EndTime, bar.Close)

        if self.macd.IsReady:
            # The current value of self.macd is represented by self.macd.Current.Value
            self.Plot("MovingAverageConvergenceDivergence", "macd", self.macd.Current.Value)
            # Plot all attributes of self.macd
            self.Plot("MovingAverageConvergenceDivergence", "fast", self.macd.Fast.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "slow", self.macd.Slow.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "signal", self.macd.Signal.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "histogram",
self.macd.Histogram.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class MovingAverageConvergenceDivergenceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.macd = MovingAverageConvergenceDivergence(12, 26, 9, MovingAverageType.Exponential)
        self.RegisterIndicator(self.symbol, self.macd, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.macd.IsReady:
            # The current value of self.macd is represented by self.macd.Current.Value
            self.Plot("MovingAverageConvergenceDivergence", "macd", self.macd.Current.Value)
            # Plot all attributes of self.macd
            self.Plot("MovingAverageConvergenceDivergence", "fast", self.macd.Fast.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "slow", self.macd.Slow.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "signal", self.macd.Signal.Current.Value)
            self.Plot("MovingAverageConvergenceDivergence", "histogram",
self.macd.Histogram.Current.Value)
```

The following reference table describes the `MovingAverageConvergenceDivergence` constructor:

INDICATORS

MovingAverageConvergenceDivergence() 1/2

```
MovingAverageConvergenceDivergence QuantConnect.Indicators.MovingAverageConvergenceDivergence (
int fastPeriod,
int slowPeriod,
int signalPeriod,
*MovingAverageType type
)
```

Creates a new MACD with the specified parameters.

Show Details

Parameters		
int	fastPeriod	The fast moving average period.
int	slowPeriod	The slow moving average period.
int	signalPeriod	The signal period.
*MovingAverageType	type	*(Optional) (Optional)* The type of moving averages to use. Default: MovingAverageType.Exponential.

Return

MovingAverageConvergenceDivergence - The new MovingAverageConvergenceDivergence indicator object.

Definition at line 64 of file Indicators/MovingAverageConvergenceDivergence.cs.

INDICATORS

MovingAverageConvergenceDivergence() 2/2

```
MovingAverageConvergenceDivergence QuantConnect.Indicators.MovingAverageConvergenceDivergence (
 string name,
 int fastPeriod,
 int slowPeriod,
 int signalPeriod,
 *MovingAverageType type
)
```

Creates a new MACD with the specified parameters.

Show Details

Parameters		
string	name	The name of this indicator.
int	fastPeriod	The fast moving average period.
int	slowPeriod	The slow moving average period.
int	signalPeriod	The signal period.
*MovingAverageType	type	*(Optional) (Optional)* The type of moving averages to use. Default: MovingAverageType.Exponential.

Return

`MovingAverageConvergenceDivergence` - The new `MovingAverageConvergenceDivergence` indicator object.

Normalized Average True Range

Introduction

This indicator computes the Normalized Average True Range (NATR). The Normalized Average True Range is calculated with the following formula: NATR = (ATR(period) / Close) * 100

To view the implementation of this indicator, see the LEAN GitHub repository .

Using NATR Indicator

To create an automatic indicators for `NormalizedAverageTrueRange` , call the `NATR` helper method from the `QCAlgorithm` class. The `NATR` method creates a `NormalizedAverageTrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class NormalizedAverageTrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.natr = self.NATR(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.natr.IsReady:
            # The current value of self.natr is represented by self.natr.Current.Value
            self.Plot("NormalizedAverageTrueRange", "natr", self.natr.Current.Value)
```

The following reference table describes the `NATR` method:

INDICATORS

NATR() 1/1

```
NormalizedAverageTrueRange QuantConnect.Algorithm.QCAlgorithm.NATR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new NormalizedAverageTrueRange indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose NATR we want.
`Int32`	period	The period over which to compute the NATR.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`NormalizedAverageTrueRange` - The NormalizedAverageTrueRange indicator for the requested symbol over the specified period.

Definition at line 1220 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `NormalizedAverageTrueRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class NormalizedAverageTrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.natr = NormalizedAverageTrueRange(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.natr.Update(bar)

        if self.natr.IsReady:
            # The current value of self.natr is represented by self.natr.Current.Value
            self.Plot("NormalizedAverageTrueRange", "natr", self.natr.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class NormalizedAverageTrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.natr = NormalizedAverageTrueRange(20)
        self.RegisterIndicator(self.symbol, self.natr, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.natr.IsReady:
            # The current value of self.natr is represented by self.natr.Current.Value
            self.Plot("NormalizedAverageTrueRange", "natr", self.natr.Current.Value)
```

The following reference table describes the NormalizedAverageTrueRange constructor:

INDICATORS

NormalizedAverageTrueRange() 1/2

```
NormalizedAverageTrueRange QuantConnect.Indicators.NormalizedAverageTrueRange (
string name,
int period
)
```

Initializes a new instance of the NormalizedAverageTrueRang class using the specified name and period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the NATR.

Return

NormalizedAverageTrueRange - The new NormalizedAverageTrueRange indicator object.

Definition at line 37 of file Indicators/NormalizedAverageTrueRange.cs.

INDICATORS

NormalizedAverageTrueRange() 2/2

```
NormalizedAverageTrueRange QuantConnect.Indicators.NormalizedAverageTrueRange (
int period
)
```

Initializes a new instance of the `NormalizedAverageTrueRang` class using the specified period.

Show Details

Parameters		
`int`	period	The period of the NATR.

Return

`NormalizedAverageTrueRange` - The new `NormalizedAverageTrueRange` indicator object.

Definition at line 49 of file Indicators/NormalizedAverageTrueRange.cs.

Visualization

The following image shows plot values of selected properties of `NormalizedAverageTrueRange` using the plotly library.

Supported Indicators

On Balance Volume

Introduction

This indicator computes the On Balance Volume (OBV). The On Balance Volume is calculated by determining the price of the current close price and previous close price. If the current close price is equivalent to the previous price the OBV remains the same, If the current close price is higher the volume of that day is added to the OBV, while a lower close price will result in negative value.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using OBV Indicator

To create an automatic indicators for `OnBalanceVolume` , call the `OBV` helper method from the `QCAlgorithm` class. The `OBV` method creates a `OnBalanceVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class OnBalanceVolumeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.obv = self.OBV(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.obv.IsReady:
            # The current value of self.obv is represented by self.obv.Current.Value
            self.Plot("OnBalanceVolume", "obv", self.obv.Current.Value)
```

The following reference table describes the `OBV` method:

INDICATORS

OBV() 1/1

```
OnBalanceVolume QuantConnect.Algorithm.QCAlgorithm.OBV (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new On Balance Volume indicator. This will compute the cumulative total volume based on whether the close price being higher or lower than the previous period. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose On Balance Volume we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`OnBalanceVolume` - The On Balance Volume indicator for the requested symbol.

Definition at line 1239 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `OnBalanceVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class OnBalanceVolumeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.obv = OnBalanceVolume()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.obv.Update(bar)

        if self.obv.IsReady:
            # The current value of self.obv is represented by self.obv.Current.Value
            self.Plot("OnBalanceVolume", "obv", self.obv.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class OnBalanceVolumeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.obv = OnBalanceVolume()
        self.RegisterIndicator(self.symbol, self.obv, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.obv.IsReady:
            # The current value of self.obv is represented by self.obv.Current.Value
            self.Plot("OnBalanceVolume", "obv", self.obv.Current.Value)
```

The following reference table describes the `OnBalanceVolume` constructor:

INDICATORS

OnBalanceVolume() 1/2

```
OnBalanceVolume QuantConnect.Indicators.OnBalanceVolume (

)
```

Initializes a new instance of the Indicator class using the specified name.

Show Details

This method requires no argument input.

Return

`OnBalanceVolume` - The new `OnBalanceVolume` indicator object.

Definition at line 34 of file Indicators/OnBalanceVolume.cs.

INDICATORS

OnBalanceVolume() 2/2

```
OnBalanceVolume QuantConnect.Indicators.OnBalanceVolume (
string name
)
```

Initializes a new instance of the Indicator class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`OnBalanceVolume` - The new `OnBalanceVolume` indicator object.

Definition at line 43 of file Indicators/OnBalanceVolume.cs.

Parabolic Stop And Reverse

Introduction

Parabolic SAR Indicator Based on TA-Lib implementation

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PSAR Indicator

To create an automatic indicators for `ParabolicStopAndReverse` , call the `PSAR` helper method from the `QCAlgorithm` class. The `PSAR` method creates a `ParabolicStopAndReverse` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class ParabolicStopAndReverseAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.psar = self.PSAR(self.symbol, 0.02, 0.02, 0.2)

    def OnData(self, slice: Slice) -> None:
        if self.psar.IsReady:
            # The current value of self.psar is represented by self.psar.Current.Value
            self.Plot("ParabolicStopAndReverse", "psar", self.psar.Current.Value)
```

The following reference table describes the `PSAR` method:

INDICATORS

PSAR() 1/1

```
ParabolicStopAndReverse QuantConnect.Algorithm.QCAlgorithm.PSAR (
Symbol symbol,
*Decimal afStart,
*Decimal afIncrement,
*Decimal afMax,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Parabolic SAR indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose PSAR we seek.
`*Decimal`	afStart	*(Optional)* Acceleration factor start value. Normally 0.02.
`*Decimal`	afIncrement	*(Optional)* Acceleration factor increment value. Normally 0.02.
`*Decimal`	afMax	*(Optional)* Acceleration factor max value. Normally 0.2.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`ParabolicStopAndReverse` - A ParabolicStopAndReverse configured with the specified periods.

Definition at line 1299 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `ParabolicStopAndReverse` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class ParabolicStopAndReverseAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.psar = ParabolicStopAndReverse(0.02, 0.02, 0.2)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.psar.Update(bar)

        if self.psar.IsReady:
            # The current value of self.psar is represented by self.psar.Current.Value
            self.Plot("ParabolicStopAndReverse", "psar", self.psar.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class ParabolicStopAndReverseAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.psar = ParabolicStopAndReverse(0.02, 0.02, 0.2)
        self.RegisterIndicator(self.symbol, self.psar, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.psar.IsReady:
            # The current value of self.psar is represented by self.psar.Current.Value
            self.Plot("ParabolicStopAndReverse", "psar", self.psar.Current.Value)
```

The following reference table describes the `ParabolicStopAndReverse` constructor:

INDICATORS

ParabolicStopAndReverse() 1/2

```
ParabolicStopAndReverse QuantConnect.Indicators.ParabolicStopAndReverse (
string name,
*decimal afStart,
*decimal afIncrement,
*decimal afMax
)
```

Create new Parabolic SAR.

Show Details

Parameters		
`string`	name	The name of this indicator.
`*decimal`	afStart	*(Optional) (Optional)* Acceleration factor start value. Default: 0.02m.
`*decimal`	afIncrement	*(Optional) (Optional)* Acceleration factor increment value. Default: 0.02m.
`*decimal`	afMax	*(Optional) (Optional)* Acceleration factor max value. Default: 0.2m.

Return

`ParabolicStopAndReverse` - The new `ParabolicStopAndReverse` indicator object.

Definition at line 44 of file Indicators/ParabolicStopAndReverse.cs.

INDICATORS

ParabolicStopAndReverse() 2/2

```
ParabolicStopAndReverse QuantConnect.Indicators.ParabolicStopAndReverse (
*decimal afStart,
*decimal afIncrement,
*decimal afMax
)
```

Create new Parabolic SAR.

Show Details

Parameters		
*decimal	afStart	*(Optional) (Optional)* Acceleration factor start value. Default: 0.02m.
*decimal	afIncrement	*(Optional) (Optional)* Acceleration factor increment value. Default: 0.02m.
*decimal	afMax	*(Optional) (Optional)* Acceleration factor max value. Default: 0.2m.

Return

`ParabolicStopAndReverse` - The new `ParabolicStopAndReverse` indicator object.

Definition at line 59 of file Indicators/ParabolicStopAndReverse.cs.

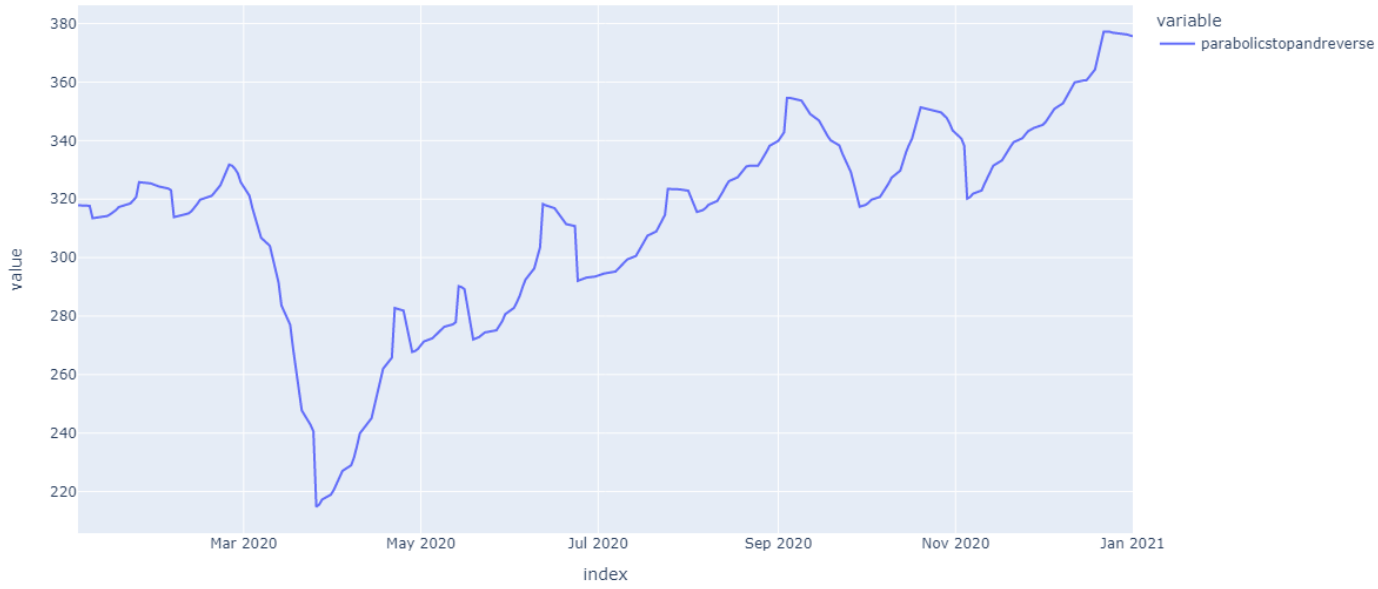
The following image shows plot values of selected properties of `ParabolicStopAndReverse` using the plotly library.

PSAR("SPY", 0.02, 0.02, 0.2)



Supported Indicators

Percentage Price Oscillator

Introduction

This indicator computes the Percentage Price Oscillator (PPO) The Percentage Price Oscillator is calculated using the following formula: PPO[i] = 100 * (FastMA[i] - SlowMA[i]) / SlowMA[i]

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PPO Indicator

To create an automatic indicators for `PercentagePriceOscillator` , call the `PPO` helper method from the `QCAlgorithm` class. The `PPO` method creates a `PercentagePriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class PercentagePriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ppo = self.PPO(self.symbol, 10, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.ppo.IsReady:
            # The current value of self.ppo is represented by self.ppo.Current.Value
            self.Plot("PercentagePriceOscillator", "ppo", self.ppo.Current.Value)
            # Plot all attributes of self.ppo
            self.Plot("PercentagePriceOscillator", "fast", self.ppo.Fast.Current.Value)
            self.Plot("PercentagePriceOscillator", "slow", self.ppo.Slow.Current.Value)
            self.Plot("PercentagePriceOscillator", "signal", self.ppo.Signal.Current.Value)
            self.Plot("PercentagePriceOscillator", "histogram", self.ppo.Histogram.Current.Value)
```

The following reference table describes the `PPO` method:

INDICATORS

PPO() 1/1

```
PercentagePriceOscillator QuantConnect.Algorithm.QCAlgorithm.PPO (
Symbol symbol,
Int32 fastPeriod,
Int32 slowPeriod,
MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new PercentagePriceOscillator indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose PPO we want.
`Int32`	fastPeriod	The fast moving average period.
`Int32`	slowPeriod	The slow moving average period.
`MovingAverageType`	movingAverageType	The type of moving average to use.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`PercentagePriceOscillator` - The PercentagePriceOscillator indicator for the requested symbol over the specified period.

Definition at line 1279 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `PercentagePriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class PercentagePriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ppo = PercentagePriceOscillator(10, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.ppo.Update(bar.EndTime, bar.Close)

        if self.ppo.IsReady:
            # The current value of self.ppo is represented by self.ppo.Current.Value
            self.Plot("PercentagePriceOscillator", "ppo", self.ppo.Current.Value)
            # Plot all attributes of self.ppo
            self.Plot("PercentagePriceOscillator", "fast", self.ppo.Fast.Current.Value)
            self.Plot("PercentagePriceOscillator", "slow", self.ppo.Slow.Current.Value)
            self.Plot("PercentagePriceOscillator", "signal", self.ppo.Signal.Current.Value)
            self.Plot("PercentagePriceOscillator", "histogram", self.ppo.Histogram.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class PercentagePriceOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ppo = PercentagePriceOscillator(10, 20, MovingAverageType.Simple)
        self.RegisterIndicator(self.symbol, self.ppo, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.ppo.IsReady:
            # The current value of self.ppo is represented by self.ppo.Current.Value
            self.Plot("PercentagePriceOscillator", "ppo", self.ppo.Current.Value)
            # Plot all attributes of self.ppo
            self.Plot("PercentagePriceOscillator", "fast", self.ppo.Fast.Current.Value)
            self.Plot("PercentagePriceOscillator", "slow", self.ppo.Slow.Current.Value)
            self.Plot("PercentagePriceOscillator", "signal", self.ppo.Signal.Current.Value)
            self.Plot("PercentagePriceOscillator", "histogram", self.ppo.Histogram.Current.Value)
```

The following reference table describes the `PercentagePriceOscillator` constructor:

INDICATORS

PercentagePriceOscillator() 1/2

```
PercentagePriceOscillator QuantConnect.Indicators.PercentagePriceOscillator (
string name,
int fastPeriod,
int slowPeriod,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the `PercentagePriceOscillato` class using the specified name and parameters.

Show Details

Parameters		
string	name	The name of this indicator.
int	fastPeriod	The fast moving average period.
int	slowPeriod	The slow moving average period.
*MovingAverageType	movingAverageType	*(Optional)* *(Optional)* The type of moving average to use. Default: MovingAverageType.Simple.

Return

PercentagePriceOscillator - The new PercentagePriceOscillator indicator object.

Pivot Points High Low

Introduction

Pivot Points (High/Low), also known as Bar Count Reversals, indicator. https://www.fidelity.com/learning-center/trading-investing/technical-analysis/technical-indicator-guide/pivot-points-high-low

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PPHL Indicator

To create an automatic indicators for `PivotPointsHighLow` , call the `PPHL` helper method from the `QCAlgorithm` class. The `PPHL` method creates a `PivotPointsHighLow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class PivotPointsHighLowAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.pphl = self.PPHL(self.symbol, 10, 10, 100)

    def OnData(self, slice: Slice) -> None:
        if self.pphl.IsReady:
            # The current value of self.pphl is represented by self.pphl.Current.Value
            self.Plot("PivotPointsHighLow", "pphl", self.pphl.Current.Value)
```

The following reference table describes the `PPHL` method:

INDICATORS

PPHL() 1/1

```
PivotPointsHighLow QuantConnect.Algorithm.QCAlgorithm.PPHL (
Symbol symbol,
Int32 lengthHigh,
Int32 lengthLow,
*Int32 lastStoredValues,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new PivotPointsHighLow indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose PPHL we seek.
`Int32`	lengthHigh	The number of surrounding bars whose high values should be less than the current bar's for the bar high to be marked as high pivot point.
`Int32`	lengthLow	The number of surrounding bars whose low values should be more than the current bar's for the bar low to be marked as low pivot point.
`*Int32`	lastStoredValues	*(Optional)* The number of last stored indicator values.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`PivotPointsHighLow` - The PivotPointsHighLow indicator for the requested symbol.

Definition at line 1259 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

        self.RegisterIndicator(self.symbol, self.pphl, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.pphl.IsReady:
            # The current value of self.pphl is represented by self.pphl.Current.Value
            self.Plot("PivotPointsHighLow", "pphl", self.pphl.Current.Value)
```

The following reference table describes the `PivotPointsHighLow` constructor:

INDICATORS

PivotPointsHighLow() 1/3

```
PivotPointsHighLow QuantConnect.Indicators.PivotPointsHighLow (
int surroundingBarsCount,
*int lastStoredValues
)
```

Creates a new instance of `PivotPointsHighLo` indicator with an equal high and low length.

Show Details

Parameters		
int	surroundingBarsCount	The length parameter here defines the number of surrounding bars that we compare against the current bar high and lows for the max/min.
*int	lastStoredValues	*(Optional) (Optional)* The number of last stored indicator values. Default: 100.

Return

`PivotPointsHighLow` - The new `PivotPointsHighLow` indicator object.

Definition at line 56 of file Indicators/PivotPointsHighLow.cs.

INDICATORS

PivotPointsHighLow() 2/3

```
PivotPointsHighLow QuantConnect.Indicators.PivotPointsHighLow (
 int surroundingBarsCountForHighPoint,
 int surroundingBarsCountForLowPoint,
 *int lastStoredValues
)
```

Creates a new instance of `PivotPointsHighLo` indicator.

Show Details

Parameters		
int	surroundingBarsCountForHighPoint	The number of surrounding bars whose high values should be less than the current bar's for the bar high to be marked as high pivot point.
int	surroundingBarsCountForLowPoint	The number of surrounding bars whose low values should be more than the current bar's for the bar low to be marked as low pivot point.
*int	lastStoredValues	*(Optional) (Optional)* The number of last stored indicator values. Default: 100.

Return

`PivotPointsHighLow` - The new `PivotPointsHighLow` indicator object.

Definition at line 66 of file Indicators/PivotPointsHighLow.cs.

INDICATORS

PivotPointsHighLow() 3/3

```
PivotPointsHighLow QuantConnect.Indicators.PivotPointsHighLow (
 string name,
 int surroundingBarsCountForHighPoint,
 int surroundingBarsCountForLowPoint,
 *int lastStoredValues
 )
```

Creates a new instance of `PivotPointsHighLo` indicator.

Show Details

Parameters		
`string`	name	The name of an indicator.
`int`	surroundingBarsCountForHighPoint	The number of surrounding bars whose high values should be less than the current bar's for the bar high to be marked as high pivot point.
`int`	surroundingBarsCountForLowPoint	The number of surrounding bars whose low values should be more than the current bar's for the bar low to be marked as low pivot point.
`*int`	lastStoredValues	*(Optional) (Optional)* The number of last stored indicator values. Default: 100.

Return

`PivotPointsHighLow` - The new `PivotPointsHighLow` indicator object.

Definition at line 78 of file Indicators/PivotPointsHighLow.cs.

Rate Of Change

Introduction

This indicator computes the n-period rate of change in a value using the following: (value_0 - value_n) / value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROC Indicator

To create an automatic indicators for `RateOfChange` , call the `ROC` helper method from the `QCAlgorithm` class. The `ROC` method creates a `RateOfChange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class RateOfChangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.roc = self.ROC(self.symbol, 10)

    def OnData(self, slice: Slice) -> None:
        if self.roc.IsReady:
            # The current value of self.roc is represented by self.roc.Current.Value
            self.Plot("RateOfChange", "roc", self.roc.Current.Value)
```

The following reference table describes the `ROC` method:

INDICATORS

ROC() 1/1

```
RateOfChange QuantConnect.Algorithm.QCAlgorithm.ROC (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new RateOfChange indicator. This will compute the n-period rate of change in the security. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RateOfChange we want.
`Int32`	period	The period over which to compute the RateOfChange.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RateOfChange` - The RateOfChange indicator for the requested symbol over the specified period.

Definition at line 1356 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `RateOfChange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class RateOfChangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.roc = RateOfChange(10)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.roc.Update(bar.EndTime, bar.Close)

        if self.roc.IsReady:
            # The current value of self.roc is represented by self.roc.Current.Value
            self.Plot("RateOfChange", "roc", self.roc.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class RateOfChangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.roc = RateOfChange(10)
        self.RegisterIndicator(self.symbol, self.roc, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.roc.IsReady:
            # The current value of self.roc is represented by self.roc.Current.Value
            self.Plot("RateOfChange", "roc", self.roc.Current.Value)
```

The following reference table describes the `RateOfChange` constructor:

INDICATORS

RateOfChange() 1/2

```
RateOfChange QuantConnect.Indicators.RateOfChange (
int period
)
```

Creates a new RateOfChange indicator with the specified period.

Show Details

Parameters		
int	period	The period over which to perform to computation.

Return

`RateOfChange` - The new `RateOfChange` indicator object.

Definition at line 40 of file Indicators/RateOfChange.cs.

INDICATORS

RateOfChange() 2/2

```
RateOfChange QuantConnect.Indicators.RateOfChange (
string name,
int period
)
```

Creates a new RateOfChange indicator with the specified period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period over which to perform to computation.

Return

`RateOfChange` - The new `RateOfChange` indicator object.

Visualization

The following image shows plot values of selected properties of `RateOfChange` using the plotly library.

Supported Indicators

Rate Of Change Percent

Introduction

This indicator computes the n-period percentage rate of change in a value using the following: 100 * (value_0 - value_n) / value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROCP Indicator

To create an automatic indicators for `RateOfChangePercent` , call the `ROCP` helper method from the `QCAlgorithm` class. The `ROCP` method creates a `RateOfChangePercent` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class RateOfChangePercentAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rocp = self.ROCP(self.symbol, 10)

    def OnData(self, slice: Slice) -> None:
        if self.rocp.IsReady:
            # The current value of self.rocp is represented by self.rocp.Current.Value
            self.Plot("RateOfChangePercent", "rocp", self.rocp.Current.Value)
```

The following reference table describes the `ROCP` method:

INDICATORS

ROCP() 1/1

```
RateOfChangePercent QuantConnect.Algorithm.QCAlgorithm.ROCP (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RateOfChangePercent indicator. This will compute the n-period percentage rate of change in the security. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RateOfChangePercent we want.
`Int32`	period	The period over which to compute the RateOfChangePercent.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RateOfChangePercent` - The RateOfChangePercent indicator for the requested symbol over the specified period.

Definition at line 1375 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `RateOfChangePercent` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class RateOfChangePercentAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rocp = RateOfChangePercent(10)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.rocp.Update(bar.EndTime, bar.Close)

        if self.rocp.IsReady:
            # The current value of self.rocp is represented by self.rocp.Current.Value
            self.Plot("RateOfChangePercent", "rocp", self.rocp.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class RateOfChangePercentAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rocp = RateOfChangePercent(10)
        self.RegisterIndicator(self.symbol, self.rocp, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.rocp.IsReady:
            # The current value of self.rocp is represented by self.rocp.Current.Value
            self.Plot("RateOfChangePercent", "rocp", self.rocp.Current.Value)
```

The following reference table describes the `RateOfChangePercent` constructor:

INDICATORS

RateOfChangePercent() 1/2

```
RateOfChangePercent QuantConnect.Indicators.RateOfChangePercent (
int period
)
```

Creates a new RateOfChangePercent indicator with the specified period.

Show Details

Parameters		
int	period	The period over which to perform to computation.

Return

`RateOfChangePercent` - The new `RateOfChangePercent` indicator object.

Supported Indicators

Rate Of Change Ratio

Introduction

This indicator computes the Rate Of Change Ratio (ROCR). The Rate Of Change Ratio is calculated with the following formula: ROCR = price / prevPrice

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROCR Indicator

To create an automatic indicators for `RateOfChangeRatio` , call the `ROCR` helper method from the `QCAlgorithm` class. The `ROCR` method creates a `RateOfChangeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class RateOfChangeRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rocr = self.ROCR(self.symbol, 10)

    def OnData(self, slice: Slice) -> None:
        if self.rocr.IsReady:
            # The current value of self.rocr is represented by self.rocr.Current.Value
            self.Plot("RateOfChangeRatio", "rocr", self.rocr.Current.Value)
```

The following reference table describes the `ROCR` method:

INDICATORS

ROCR() 1/1

```
RateOfChangeRatio QuantConnect.Algorithm.QCAlgorithm.ROCR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RateOfChangeRatio indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ROCR we want.
`Int32`	period	The period over which to compute the ROCR.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RateOfChangeRatio` - The RateOfChangeRatio indicator for the requested symbol over the specified period.

Definition at line 1393 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `RateOfChangeRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class RateOfChangeRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rocr = RateOfChangeRatio(10)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.rocr.Update(bar.EndTime, bar.Close)

        if self.rocr.IsReady:
            # The current value of self.rocr is represented by self.rocr.Current.Value
            self.Plot("RateOfChangeRatio", "rocr", self.rocr.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class RateOfChangeRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rocr = RateOfChangeRatio(10)
        self.RegisterIndicator(self.symbol, self.rocr, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.rocr.IsReady:
            # The current value of self.rocr is represented by self.rocr.Current.Value
            self.Plot("RateOfChangeRatio", "rocr", self.rocr.Current.Value)
```

The following reference table describes the `RateOfChangeRatio` constructor:

INDICATORS

RateOfChangeRatio() 1/2

```
RateOfChangeRatio QuantConnect.Indicators.RateOfChangeRatio (
string name,
int period
)
```

Initializes a new instance of the `RateOfChangeRati` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the ROCR.

Return

`RateOfChangeRatio` - The new `RateOfChangeRatio` indicator object.

Definition at line 30 of file Indicators/RateOfChangeRatio.cs.

INDICATORS

RateOfChangeRatio() 2/2

```
RateOfChangeRatio QuantConnect.Indicators.RateOfChangeRatio (
int period
)
```

Initializes a new instance of the `RateOfChangeRati` class using the specified period.

Show Details

Parameters		
`int`	period	The period of the ROCR.

Return

`RateOfChangeRatio` - The new `RateOfChangeRatio` indicator object.

Supported Indicators

Regression Channel

Introduction

The Regression Channel indicator extends the with the inclusion of two (upper and lower) channel lines that are distanced from the linear regression line by a user defined number of standard deviations. Reference: http://www.onlinetradingconcepts.com/TechnicalAnalysis/LinRegChannel.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RC Indicator

To create an automatic indicators for `RegressionChannel` , call the `RC` helper method from the `QCAlgorithm` class. The `RC` method creates a `RegressionChannel` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class RegressionChannelAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rc = self.RC(self.symbol, 20, 2)

    def OnData(self, slice: Slice) -> None:
        if self.rc.IsReady:
            # The current value of self.rc is represented by self.rc.Current.Value
            self.Plot("RegressionChannel", "rc", self.rc.Current.Value)
            # Plot all attributes of self.rc
            self.Plot("RegressionChannel", "linearregression", self.rc.LinearRegression.Current.Value)
            self.Plot("RegressionChannel", "upperchannel", self.rc.UpperChannel.Current.Value)
            self.Plot("RegressionChannel", "lowerchannel", self.rc.LowerChannel.Current.Value)
            self.Plot("RegressionChannel", "intercept", self.rc.Intercept.Current.Value)
            self.Plot("RegressionChannel", "slope", self.rc.Slope.Current.Value)
```

The following reference table describes the `RC` method:

INDICATORS

RC() 1/1

```
RegressionChannel QuantConnect.Algorithm.QCAlgorithm.RC (
Symbol symbol,
Int32 period,
Decimal k,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RegressionChannel indicator which will compute the LinearRegression, UpperChannel and

LowerChannel lines, the intercept and slope.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RegressionChannel we seek.
`Int32`	period	The period of the standard deviation and least square moving average (linear regression line).
`Decimal`	k	The number of standard deviations specifying the distance between the linear regression and upper or lower channel lines.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RegressionChannel` - A Regression Channel configured with the specified period and number of standard deviation.

Definition at line 1318 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `RegressionChannel` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```
class RegressionChannelAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rc = RegressionChannel(20, 2)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.rc.Update(bar.EndTime, bar.Close)

        if self.rc.IsReady:
            # The current value of self.rc is represented by self.rc.Current.Value
            self.Plot("RegressionChannel", "rc", self.rc.Current.Value)
            # Plot all attributes of self.rc
            self.Plot("RegressionChannel", "linearregression", self.rc.LinearRegression.Current.Value)
            self.Plot("RegressionChannel", "upperchannel", self.rc.UpperChannel.Current.Value)
            self.Plot("RegressionChannel", "lowerchannel", self.rc.LowerChannel.Current.Value)
            self.Plot("RegressionChannel", "intercept", self.rc.Intercept.Current.Value)
            self.Plot("RegressionChannel", "slope", self.rc.Slope.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class RegressionChannelAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rc = RegressionChannel(20, 2)
        self.RegisterIndicator(self.symbol, self.rc, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.rc.IsReady:
            # The current value of self.rc is represented by self.rc.Current.Value
            self.Plot("RegressionChannel", "rc", self.rc.Current.Value)
            # Plot all attributes of self.rc
            self.Plot("RegressionChannel", "linearregression", self.rc.LinearRegression.Current.Value)
            self.Plot("RegressionChannel", "upperchannel", self.rc.UpperChannel.Current.Value)
            self.Plot("RegressionChannel", "lowerchannel", self.rc.LowerChannel.Current.Value)
            self.Plot("RegressionChannel", "intercept", self.rc.Intercept.Current.Value)
            self.Plot("RegressionChannel", "slope", self.rc.Slope.Current.Value)
```

The following reference table describes the `RegressionChannel` constructor:

INDICATORS

RegressionChannel() 1/2

```
RegressionChannel QuantConnect.Indicators.RegressionChannel (
string name,
int period,
decimal k
)
```

Initializes a new instance of the `RegressionChanne` class.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The number of data points to hold in the window.
decimal	k	The number of standard deviations specifying the distance between the linear regression and upper or lower channel lines.

Return

`RegressionChannel` - The new `RegressionChannel` indicator object.

Definition at line 72 of file Indicators/RegressionChannel.cs.

INDICATORS

RegressionChannel() 2/2

```
RegressionChannel QuantConnect.Indicators.RegressionChannel (
int period,
decimal k
)
```

Initializes a new instance of the `LeastSquaresMovingAverag` class.

Show Details

Parameters		
int	period	The number of data points to hold in the window.
decimal	k	The number of standard deviations specifying the distance between the linear regression and upper or lower channel lines.

Return

`RegressionChannel` - The new `RegressionChannel` indicator object.

Definition at line 87 of file Indicators/RegressionChannel.cs.

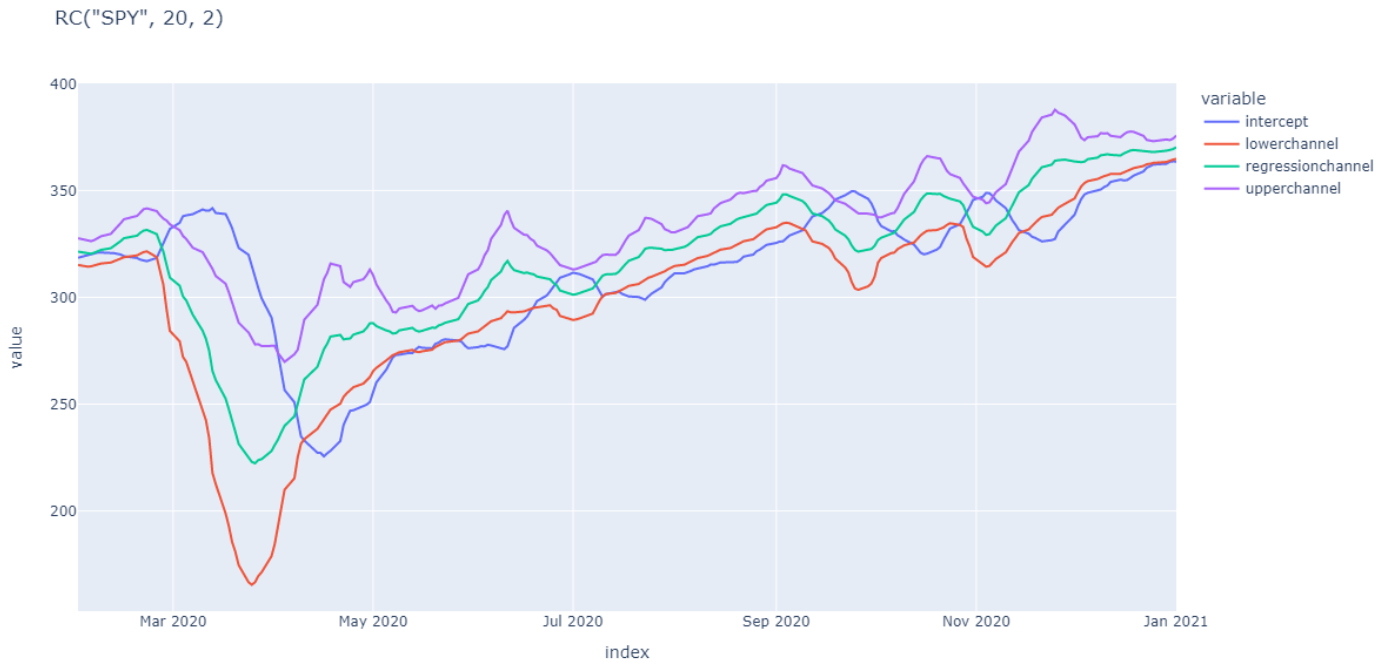
The following image shows plot values of selected properties of `RegressionChannel` using the plotly library.



Supported Indicators

Relative Daily Volume

Introduction

The Relative Daily Volume indicator is an indicator that compares current cumulative volume to the cumulative volume for a given time of day, measured as a ratio. Current volume from open to current time of day / Average over the past x days from open to current time of day

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RDV Indicator

To create an automatic indicators for `RelativeDailyVolume` , call the `RDV` helper method from the `QCAlgorithm` class. The `RDV` method creates a `RelativeDailyVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class RelativeDailyVolumeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rdv = self.RDV(self.symbol, 2)

    def OnData(self, slice: Slice) -> None:
        if self.rdv.IsReady:
            # The current value of self.rdv is represented by self.rdv.Current.Value
            self.Plot("RelativeDailyVolume", "rdv", self.rdv.Current.Value)
```

The following reference table describes the `RDV` method:

INDICATORS

RDV() 1/1

```
RelativeDailyVolume QuantConnect.Algorithm.QCAlgorithm.RDV (
Symbol symbol,
*Int32 period,
*Resolution resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an RelativeDailyVolume indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RDV we want.
`*Int32`	period	*(Optional)* The period of the RDV.
`*Resolution`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`RelativeDailyVolume` - The Relative Volume indicator for the given parameters.

Definition at line 1450 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `RelativeDailyVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class RelativeDailyVolumeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rdv = RelativeDailyVolume(2)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.rdv.Update(bar)

        if self.rdv.IsReady:
            # The current value of self.rdv is represented by self.rdv.Current.Value
            self.Plot("RelativeDailyVolume", "rdv", self.rdv.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class RelativeDailyVolumeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rdv = RelativeDailyVolume(2)
        self.RegisterIndicator(self.symbol, self.rdv, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.rdv.IsReady:
            # The current value of self.rdv is represented by self.rdv.Current.Value
            self.Plot("RelativeDailyVolume", "rdv", self.rdv.Current.Value)
```

The following reference table describes the `RelativeDailyVolume` constructor:

INDICATORS

RelativeDailyVolume() 1/2

```
RelativeDailyVolume QuantConnect.Indicators.RelativeDailyVolume (
*int period
)
```

Initializes a new instance of the RelativeDailyVolume class using the specified period.

Show Details

Parameters		
*int	period	*(Optional) (Optional)* The period over which to perform the computation. Default: 2.

Return

`RelativeDailyVolume` - The new `RelativeDailyVolume` indicator object.

Definition at line 50 of file Indicators/RelativeDailyVolume.cs.

INDICATORS

RelativeDailyVolume() 2/2

```
RelativeDailyVolume QuantConnect.Indicators.RelativeDailyVolume (
string name,
int period
)
```

Creates a new RelativeDailyVolume indicator with the specified period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of this indicator.

Return

`RelativeDailyVolume` - The new `RelativeDailyVolume` indicator object.

Definition at line 60 of file Indicators/RelativeDailyVolume.cs.

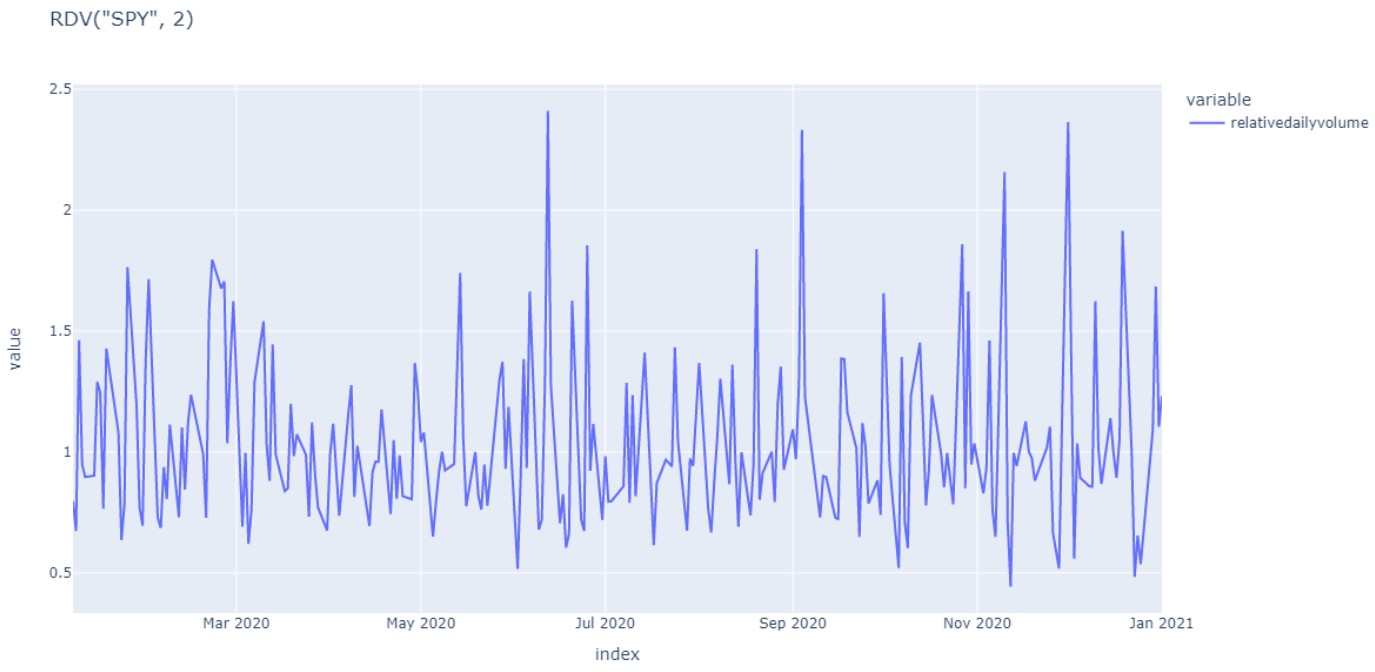
The following image shows plot values of selected properties of `RelativeDailyVolume` using the plotly library.



Supported Indicators

Relative Moving Average

Introduction

This indicator represents the relative moving average indicator (RMA). RMA = SMA(3 x Period) - SMA(2 x Period) + SMA(1 x Period) per formula: https://www.hybrid-solutions.com/plugins/client-vtl-plugins/free/rma.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RMA Indicator

To create an automatic indicators for `RelativeMovingAverage` , call the `RMA` helper method from the `QCAlgorithm` class. The `RMA` method creates a `RelativeMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class RelativeMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rma = self.RMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.rma.IsReady:
            # The current value of self.rma is represented by self.rma.Current.Value
            self.Plot("RelativeMovingAverage", "rma", self.rma.Current.Value)
            # Plot all attributes of self.rma
            self.Plot("RelativeMovingAverage", "shortaverage", self.rma.ShortAverage.Current.Value)
            self.Plot("RelativeMovingAverage", "mediumaverage", self.rma.MediumAverage.Current.Value)
            self.Plot("RelativeMovingAverage", "longaverage", self.rma.LongAverage.Current.Value)
```

The following reference table describes the `RMA` method:

INDICATORS

RMA() 1/1

```
RelativeMovingAverage QuantConnect.Algorithm.QCAlgorithm.RMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Relative Moving Average indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose relative moving average we seek.
`Int32`	period	The period of the relative moving average.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RelativeMovingAverage` - A relative moving average configured with the specified period and number of standard deviation.

Definition at line 1336 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `RelativeMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class RelativeMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rma = RelativeMovingAverage(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.rma.Update(bar.EndTime, bar.Close)

        if self.rma.IsReady:
            # The current value of self.rma is represented by self.rma.Current.Value
            self.Plot("RelativeMovingAverage", "rma", self.rma.Current.Value)
            # Plot all attributes of self.rma
            self.Plot("RelativeMovingAverage", "shortaverage", self.rma.ShortAverage.Current.Value)
            self.Plot("RelativeMovingAverage", "mediumaverage", self.rma.MediumAverage.Current.Value)
            self.Plot("RelativeMovingAverage", "longaverage", self.rma.LongAverage.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class RelativeMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rma = RelativeMovingAverage(20)
        self.RegisterIndicator(self.symbol, self.rma, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.rma.IsReady:
            # The current value of self.rma is represented by self.rma.Current.Value
            self.Plot("RelativeMovingAverage", "rma", self.rma.Current.Value)
            # Plot all attributes of self.rma
            self.Plot("RelativeMovingAverage", "shortaverage", self.rma.ShortAverage.Current.Value)
            self.Plot("RelativeMovingAverage", "mediumaverage", self.rma.MediumAverage.Current.Value)
            self.Plot("RelativeMovingAverage", "longaverage", self.rma.LongAverage.Current.Value)
```

The following reference table describes the `RelativeMovingAverage` constructor:

INDICATORS

RelativeMovingAverage() 1/2

```
RelativeMovingAverage QuantConnect.Indicators.RelativeMovingAverage (
string name,
int period
)
```

Initializes a new instance of the RelativeMovingAverage class with the specified name and period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the RMA.

Return

`RelativeMovingAverage` - The new `RelativeMovingAverage` indicator object.

Definition at line 55 of file Indicators/RelativeMovingAverage.cs.

INDICATORS

RelativeMovingAverage() 2/2

```
RelativeMovingAverage QuantConnect.Indicators.RelativeMovingAverage (
int period
)
```

Initializes a new instance of the SimpleMovingAverage class with the default name and period.

Show Details

Parameters		
int	period	/

Return

`RelativeMovingAverage` - The new `RelativeMovingAverage` indicator object.

Definition at line 67 of file Indicators/RelativeMovingAverage.cs.

Relative Strength Index

Introduction

This indicator represents the Relative Strength Index (RSI) developed by K. Welles Wilder. You can optionally specified a different moving average type to be used in the computation

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RSI Indicator

To create an automatic indicators for `RelativeStrengthIndex` , call the `RSI` helper method from the `QCAlgorithm` class. The `RSI` method creates a `RelativeStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class RelativeStrengthIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rsi = self.RSI(self.symbol, 14)

    def OnData(self, slice: Slice) -> None:
        if self.rsi.IsReady:
            # The current value of self.rsi is represented by self.rsi.Current.Value
            self.Plot("RelativeStrengthIndex", "rsi", self.rsi.Current.Value)
            # Plot all attributes of self.rsi
            self.Plot("RelativeStrengthIndex", "averageloss", self.rsi.AverageLoss.Current.Value)
            self.Plot("RelativeStrengthIndex", "averagegain", self.rsi.AverageGain.Current.Value)
```

The following reference table describes the `RSI` method:

INDICATORS

RSI() 1/1

```
RelativeStrengthIndex QuantConnect.Algorithm.QCAlgorithm.RSI (
Symbol symbol,
Int32 period,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RelativeStrengthIndex indicator. This will produce an oscillator that ranges from 0 to 100 based on the ratio of average gains to average losses over the specified period.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RSI we want.
`Int32`	period	The period over which to compute the RSI.
`*MovingAverageType`	movingAverageType	*(Optional)* The type of moving average to use in computing the average gain/loss values.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RelativeStrengthIndex` - The RelativeStrengthIndex indicator for the requested symbol over the specified period.

Definition at line 1413 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `RelativeStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class RelativeStrengthIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rsi = RelativeStrengthIndex(14)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.rsi.Update(bar.EndTime, bar.Close)

        if self.rsi.IsReady:
            # The current value of self.rsi is represented by self.rsi.Current.Value
            self.Plot("RelativeStrengthIndex", "rsi", self.rsi.Current.Value)
            # Plot all attributes of self.rsi
            self.Plot("RelativeStrengthIndex", "averageloss", self.rsi.AverageLoss.Current.Value)
            self.Plot("RelativeStrengthIndex", "averagegain", self.rsi.AverageGain.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class RelativeStrengthIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rsi = RelativeStrengthIndex(14)
        self.RegisterIndicator(self.symbol, self.rsi, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.rsi.IsReady:
            # The current value of self.rsi is represented by self.rsi.Current.Value
            self.Plot("RelativeStrengthIndex", "rsi", self.rsi.Current.Value)
            # Plot all attributes of self.rsi
            self.Plot("RelativeStrengthIndex", "averageloss", self.rsi.AverageLoss.Current.Value)
            self.Plot("RelativeStrengthIndex", "averagegain", self.rsi.AverageGain.Current.Value)
```

The following reference table describes the `RelativeStrengthIndex` constructor:

INDICATORS

RelativeStrengthIndex() 1/2

```
RelativeStrengthIndex QuantConnect.Indicators.RelativeStrengthIndex (
int period,
*MovingAverageType movingAverageType
)
```

Initializes a new instance of the RelativeStrengthIndex class with the specified name and period.

Show Details

Parameters		
int	period	The period used for up and down days.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of moving average to be used for computing the average gain/loss values. Default: MovingAverageType.Wilders.

Return

RelativeStrengthIndex - The new RelativeStrengthIndex indicator object.

Definition at line 48 of file Indicators/RelativeStrengthIndex.cs.

INDICATORS

RelativeStrengthIndex() 2/2

```
RelativeStrengthIndex QuantConnect.Indicators.RelativeStrengthIndex (
string name,

Relative Vigor Index

Introduction

The Relative Vigor Index (RVI) compares the ratio of the closing price of a security to its trading range. For illustration, let: a = Close−Open b = Close−Open of One Bar Prior to a c = Close−Open of One Bar Prior to b d = Close−Open of One Bar Prior to c e = High−Low of Bar a f = High−Low of Bar b g = High−Low of Bar c h = High−Low of Bar d Then let (a+2*(b+c)+d)/6 be NUM and (e+2*(f+g)+h)/6 be DENOM. RVI = SMA(NUM)/SMA(DENOM) for a specified period. https://www.investopedia.com/terms/r/relative_vigor_index.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RVI Indicator

To create an automatic indicators for `RelativeVigorIndex` , call the `RVI` helper method from the `QCAlgorithm` class. The `RVI` method creates a `RelativeVigorIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class RelativeVigorIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rvi = self.RVI(self.symbol, 20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        if self.rvi.IsReady:
            # The current value of self.rvi is represented by self.rvi.Current.Value
            self.Plot("RelativeVigorIndex", "rvi", self.rvi.Current.Value)
            # Plot all attributes of self.rvi
            self.Plot("RelativeVigorIndex", "signal", self.rvi.Signal.Current.Value)
```

The following reference table describes the `RVI` method:

INDICATORS

RVI() 1/1

```
RelativeVigorIndex QuantConnect.Algorithm.QCAlgorithm.RVI (
 Symbol symbol,
 Int32 period,
 *MovingAverageType movingAverageType,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates a new RelativeVigorIndex indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RVI we want.
`Int32`	period	The period over which to compute the RVI.
`*MovingAverageType`	movingAverageType	*(Optional)* The type of moving average to use.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`RelativeVigorIndex` - The RelativeVigorIndex indicator for the requested symbol over the specified period.

Definition at line 1431 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```py
class RelativeVigorIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rvi = RelativeVigorIndex(20, MovingAverageType.Simple)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.rvi.Update(bar)

        if self.rvi.IsReady:
            # The current value of self.rvi is represented by self.rvi.Current.Value
            self.Plot("RelativeVigorIndex", "rvi", self.rvi.Current.Value)
            # Plot all attributes of self.rvi
            self.Plot("RelativeVigorIndex", "signal", self.rvi.Signal.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class RelativeVigorIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.rvi = RelativeVigorIndex(20, MovingAverageType.Simple)
        self.RegisterIndicator(self.symbol, self.rvi, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.rvi.IsReady:
            # The current value of self.rvi is represented by self.rvi.Current.Value
            self.Plot("RelativeVigorIndex", "rvi", self.rvi.Current.Value)
            # Plot all attributes of self.rvi
            self.Plot("RelativeVigorIndex", "signal", self.rvi.Signal.Current.Value)
```

The following reference table describes the `RelativeVigorIndex` constructor:

INDICATORS

RelativeVigorIndex() 1/2

```
RelativeVigorIndex QuantConnect.Indicators.RelativeVigorIndex (
int period,
MovingAverageType type
)
```

Initializes a new instance of the `RelativeVigorInde` (RVI) class.

Show Details

Parameters		
`int`	period	The period for the RelativeVigorIndex.

Schaff Trend Cycle

Introduction

This indicator creates the Schaff Trend Cycle

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STC Indicator

To create an automatic indicators for `SchaffTrendCycle` , call the `STC` helper method from the `QCAlgorithm` class. The `STC` method creates a `SchaffTrendCycle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class SchaffTrendCycleAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.stc = self.STC(self.symbol, 5, 10, 20, MovingAverageType.Exponential)

    def OnData(self, slice: Slice) -> None:
        if self.stc.IsReady:
            # The current value of self.stc is represented by self.stc.Current.Value
            self.Plot("SchaffTrendCycle", "stc", self.stc.Current.Value)
```

The following reference table describes the `STC` method:

INDICATORS

STC() 1/1

```
SchaffTrendCycle QuantConnect.Algorithm.QCAlgorithm.STC (
Symbol symbol,
Int32 cyclePeriod,
Int32 fastPeriod,
Int32 slowPeriod,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Schaff Trend Cycle indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol for the indicator to track.
`Int32`	cyclePeriod	The signal period.
`Int32`	fastPeriod	The fast moving average period.
`Int32`	slowPeriod	The slow moving average period.
`*MovingAverageType`	movingAverageType	*(Optional)* The type of moving average to use.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`SchaffTrendCycle` - The SchaffTrendCycle indicator for the requested symbol over the specified period.

Definition at line 1549 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

        self.stc = SchaffTrendCycle(5, 10, 20, MovingAverageType.Exponential)
        self.RegisterIndicator(self.symbol, self.stc, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.stc.IsReady:
            # The current value of self.stc is represented by self.stc.Current.Value
            self.Plot("SchaffTrendCycle", "stc", self.stc.Current.Value)
```

The following reference table describes the `SchaffTrendCycle` constructor:

INDICATORS

SchaffTrendCycle() 1/2

```
SchaffTrendCycle QuantConnect.Indicators.SchaffTrendCycle (
*int fastPeriod,
*int slowPeriod,
*int cyclePeriod,
*MovingAverageType type
)
```

https://www.tradingpedia.com/forex-trading-indicators/schaff-trend-cycle.

Show Details

Parameters		
*int	fastPeriod	*(Optional) (Optional)* The fast moving average period. Default: 23.
*int	slowPeriod	*(Optional) (Optional)* The slow moving average period. Default: 50.
*int	cyclePeriod	*(Optional) (Optional)* The signal period. Default: 10.
*MovingAverageType	type	*(Optional) (Optional)* The type of moving averages to use. Default: MovingAverageType.Exponential.

Return

SchaffTrendCycle - The new SchaffTrendCycle indicator object.

Definition at line 58 of file Indicators/SchaffTrendCycle.cs.

INDICATORS

SchaffTrendCycle() 2/2

```
SchaffTrendCycle QuantConnect.Indicators.SchaffTrendCycle (
 string name,
 int fastPeriod,
 int slowPeriod,
 int cyclePeriod,
 MovingAverageType type
 )
```

Creates a new schaff trend cycle with the specified parameters.

Show Details

Parameters		
string	name	The name of this indicator.
int	fastPeriod	The fast moving average period.
int	slowPeriod	The slow moving average period.
int	cyclePeriod	The signal period.
MovingAverageType	type	The type of moving averages to use.

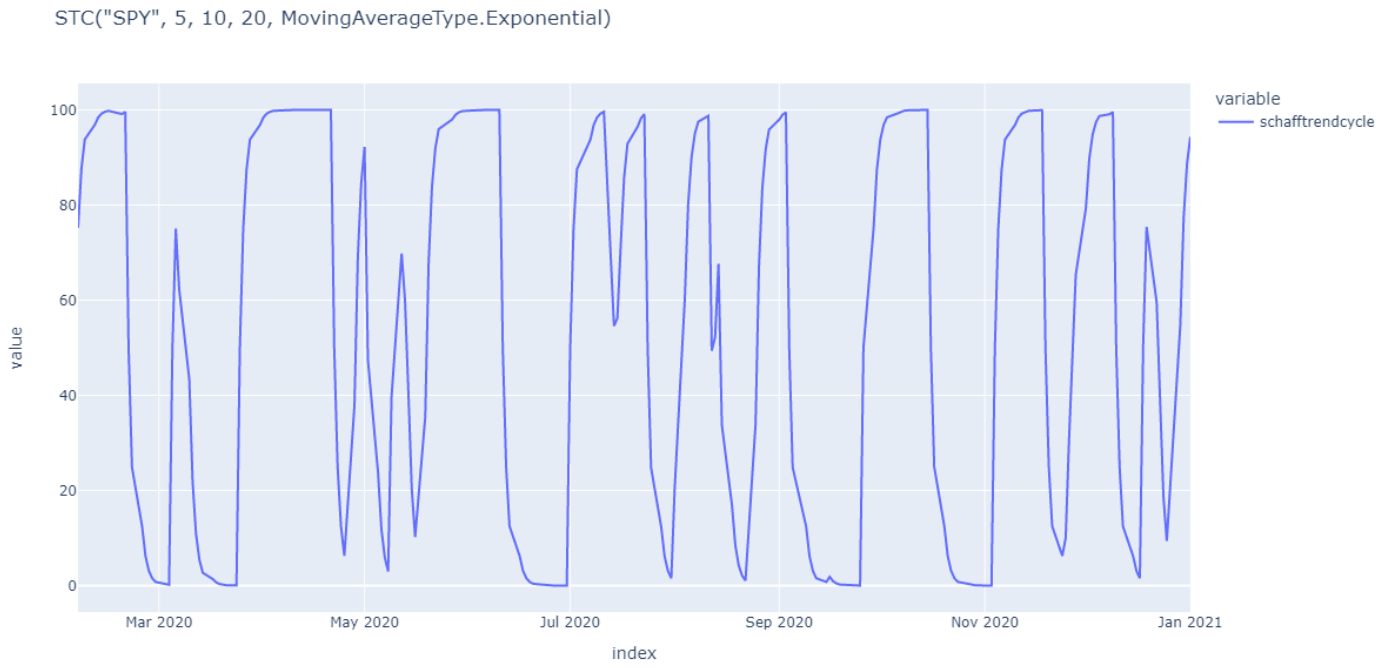
Return

`SchaffTrendCycle` - The new `SchaffTrendCycle` indicator object.

Definition at line 71 of file Indicators/SchaffTrendCycle.cs.

Visualization

The following image shows plot values of selected properties of `SchaffTrendCycle` using the plotly library.



Supported Indicators

Sharpe Ratio

Introduction

Calculation of the Sharpe Ratio (SR) developed by William F. Sharpe. Reference: https://www.investopedia.com/articles/07/sharpe_ratio.asp Formula: S(x) = (Rx - Rf) / stdDev(Rx) Where: S(x) - sharpe ratio of x Rx - average rate of return for x Rf - risk-free rate

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SR Indicator

To create an automatic indicators for `SharpeRatio` , call the `SR` helper method from the `QCAlgorithm` class. The `SR` method creates a `SharpeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class SharpeRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sr = self.SR(self.symbol, 22, 0.03)

    def OnData(self, slice: Slice) -> None:
        if self.sr.IsReady:
            # The current value of self.sr is represented by self.sr.Current.Value
            self.Plot("SharpeRatio", "sr", self.sr.Current.Value)
```

The following reference table describes the `SR` method:

INDICATORS

SR() 1/1

```
SharpeRatio QuantConnect.Algorithm.QCAlgorithm.SR (
Symbol symbol,
Int32 sharpePeriod,
*Decimal riskFreeRate,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RollingSharpeRatio indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RSR we want.
`Int32`	sharpePeriod	Period of historical observation for sharpe ratio calculation.
`*Decimal`	riskFreeRate	*(Optional)* Risk-free rate for sharpe ratio calculation.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`SharpeRatio` - The RollingSharpeRatio indicator for the requested symbol over the specified period.

Definition at line 1489 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `SharpeRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class SharpeRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sr = SharpeRatio(22, 0.03)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.sr.Update(bar.EndTime, bar.Close)

        if self.sr.IsReady:
            # The current value of self.sr is represented by self.sr.Current.Value
            self.Plot("SharpeRatio", "sr", self.sr.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class SharpeRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sr = SharpeRatio(22, 0.03)
        self.RegisterIndicator(self.symbol, self.sr, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.sr.IsReady:
            # The current value of self.sr is represented by self.sr.Current.Value
            self.Plot("SharpeRatio", "sr", self.sr.Current.Value)
```

The following reference table describes the SharpeRatio constructor:

INDICATORS

SharpeRatio() 1/2

```
SharpeRatio QuantConnect.Indicators.SharpeRatio (
string name,
int period,
*decimal riskFreeRate
)
```

Creates a new Sharpe Ratio indicator using the specified periods.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	Period of historical observation for sharpe ratio calculation.
*decimal	riskFreeRate	*(Optional) (Optional)* Risk-free rate for sharpe ratio calculation. Default: 0.0m.

Return

SharpeRatio - The new SharpeRatio indicator object.

Definition at line 66 of file Indicators/SharpeRatio.cs.

INDICATORS

SharpeRatio() 2/2

```
SharpeRatio QuantConnect.Indicators.SharpeRatio (
int period,
*decimal riskFreeRate
)
```

Creates a new SharpeRatio indicator using the specified periods.

Show Details

Parameters		
int	period	Period of historical observation for sharpe ratio calculation.
*decimal	riskFreeRate	*(Optional) (Optional)* Risk-free rate for sharpe ratio calculation. Default: 0.0m.

Return

SharpeRatio - The new SharpeRatio indicator object.

Simple Moving Average

Introduction

This indicator represents the traditional simple moving average indicator (SMA)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SMA Indicator

To create an automatic indicators for `SimpleMovingAverage` , call the `SMA` helper method from the `QCAlgorithm` class. The `SMA` method creates a `SimpleMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class SimpleMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sma = self.SMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.sma.IsReady:
            # The current value of self.sma is represented by self.sma.Current.Value
            self.Plot("SimpleMovingAverage", "sma", self.sma.Current.Value)
            # Plot all attributes of self.sma
            self.Plot("SimpleMovingAverage", "rollingsum", self.sma.RollingSum.Current.Value)
```

The following reference table describes the `SMA` method:

INDICATORS

SMA() 1/1

```
SimpleMovingAverage QuantConnect.Algorithm.QCAlgorithm.SMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates an SimpleMovingAverage indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose SMA we want.
`Int32`	period	The period of the SMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`SimpleMovingAverage` - The SimpleMovingAverage for the given parameters.

Definition at line 1528 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `SimpleMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class SimpleMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sma = SimpleMovingAverage(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.sma.Update(bar.EndTime, bar.Close)

        if self.sma.IsReady:
            # The current value of self.sma is represented by self.sma.Current.Value
            self.Plot("SimpleMovingAverage", "sma", self.sma.Current.Value)
            # Plot all attributes of self.sma
            self.Plot("SimpleMovingAverage", "rollingsum", self.sma.RollingSum.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class SimpleMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sma = SimpleMovingAverage(20)
        self.RegisterIndicator(self.symbol, self.sma, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.sma.IsReady:
            # The current value of self.sma is represented by self.sma.Current.Value
            self.Plot("SimpleMovingAverage", "sma", self.sma.Current.Value)
            # Plot all attributes of self.sma
            self.Plot("SimpleMovingAverage", "rollingsum", self.sma.RollingSum.Current.Value)
```

The following reference table describes the `SimpleMovingAverage` constructor:

INDICATORS

SimpleMovingAverage() 1/2

```
SimpleMovingAverage QuantConnect.Indicators.SimpleMovingAverage (
string name,
int period
)
```

Initializes a new instance of the SimpleMovingAverage class with the specified name and period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the SMA.

Return

`SimpleMovingAverage` - The new `SimpleMovingAverage` indicator object.

Definition at line 47 of file Indicators/SimpleMovingAverage.cs.

INDICATORS

SimpleMovingAverage() 2/2

```
SimpleMovingAverage QuantConnect.Indicators.SimpleMovingAverage (
int period
)
```

Initializes a new instance of the SimpleMovingAverage class with the default name and period.

Show Details

Parameters		
int	period	The period of the SMA.

Return

`SimpleMovingAverage` - The new `SimpleMovingAverage` indicator object.

Supported Indicators

Sortino Ratio

Introduction

Calculation of the Sortino Ratio, a modification of the . Reference: https://www.cmegroup.com/education/files/rr-sortino-a-sharper-ratio.pdf Formula: S(x) = (R - T) / TDD Where: S(x) - Sortino ratio of x R - the average period return T - the target or required rate of return for the investment strategy under consideration. In Sortino's early work, T was originally known as the minimum acceptable return, or MAR. In his more recent work, MAR is now referred to as the Desired Target Return. TDD - the target downside deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SORTINO Indicator

To create an automatic indicators for `SortinoRatio` , call the `SORTINO` helper method from the `QCAlgorithm` class. The `SORTINO` method creates a `SortinoRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class SortinoRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sortino = self.SORTINO(self.symbol, 22)

    def OnData(self, slice: Slice) -> None:
        if self.sortino.IsReady:
            # The current value of self.sortino is represented by self.sortino.Current.Value
            self.Plot("SortinoRatio", "sortino", self.sortino.Current.Value)
```

The following reference table describes the `SORTINO` method:

INDICATORS

SORTINO() 1/1

```
SortinoRatio QuantConnect.Algorithm.QCAlgorithm.SORTINO (
Symbol symbol,
Int32 sortinoPeriod,
*Double minimumAcceptableReturn,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Sortino indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Sortino we want.
`Int32`	sortinoPeriod	Period of historical observation for Sortino ratio calculation.
`*Double`	minimumAcceptableReturn	*(Optional)* Minimum acceptable return (eg risk-free rate) for the Sortino ratio calculation.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`SortinoRatio` - The SortinoRatio indicator for the requested symbol over the specified period.

Definition at line 1508 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `SortinoRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class SortinoRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sortino = SortinoRatio(22)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.sortino.Update(bar.EndTime, bar.Close)

        if self.sortino.IsReady:
            # The current value of self.sortino is represented by self.sortino.Current.Value
            self.Plot("SortinoRatio", "sortino", self.sortino.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class SortinoRatioAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sortino = SortinoRatio(22)
        self.RegisterIndicator(self.symbol, self.sortino, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.sortino.IsReady:
            # The current value of self.sortino is represented by self.sortino.Current.Value
            self.Plot("SortinoRatio", "sortino", self.sortino.Current.Value)
```

The following reference table describes the `SortinoRatio` constructor:

INDICATORS

SortinoRatio() 1/2

```
SortinoRatio QuantConnect.Indicators.SortinoRatio (
string name,
int period,
*double minimumAcceptableReturn
)
```

Creates a new Sortino Ratio indicator using the specified periods.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	Period of historical observation for Sortino ratio calculation.
*double	minimumAcceptableReturn	*(Optional)* *(Optional)* Minimum acceptable return for Sortino ratio calculation. Default: 0.

Return

`SortinoRatio` - The new `SortinoRatio` indicator object.

Standard Deviation

Introduction

This indicator computes the n-period population standard deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STD Indicator

To create an automatic indicators for `StandardDeviation` , call the `STD` helper method from the `QCAlgorithm` class. The `STD` method creates a `StandardDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class StandardDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.std = self.STD(self.symbol, 22)

    def OnData(self, slice: Slice) -> None:
        if self.std.IsReady:
            # The current value of self.std is represented by self.std.Current.Value
            self.Plot("StandardDeviation", "std", self.std.Current.Value)
```

The following reference table describes the `STD` method:

INDICATORS

STD() 1/1

```
StandardDeviation QuantConnect.Algorithm.QCAlgorithm.STD (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new StandardDeviation indicator. This will return the population standard deviation of samples over the specified period.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose STD we want.
`Int32`	period	The period over which to compute the STD.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`StandardDeviation` - The StandardDeviation indicator for the requested symbol over the specified period.

Definition at line 1567 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `StandardDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class StandardDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.std = StandardDeviation(22)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.std.Update(bar.EndTime, bar.Close)

        if self.std.IsReady:
            # The current value of self.std is represented by self.std.Current.Value
            self.Plot("StandardDeviation", "std", self.std.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class StandardDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.std = StandardDeviation(22)
        self.RegisterIndicator(self.symbol, self.std, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.std.IsReady:
            # The current value of self.std is represented by self.std.Current.Value
            self.Plot("StandardDeviation", "std", self.std.Current.Value)
```

The following reference table describes the `StandardDeviation` constructor:

INDICATORS

StandardDeviation() 1/2

```
StandardDeviation QuantConnect.Indicators.StandardDeviation (
int period
)
```

On a data set of size N will use an N normalizer and would thus be biased if applied to a subset.

Show Details

Parameters		
int	period	The sample size of the standard deviation.

Return

`StandardDeviation` - The new `StandardDeviation` indicator object.

Definition at line 32 of file Indicators/StandardDeviation.cs.

INDICATORS

StandardDeviation() 2/2

```
StandardDeviation QuantConnect.Indicators.StandardDeviation (
string name,
int period
)
```

On a data set of size N will use an N normalizer and would thus be biased if applied to a subset.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The sample size of the standard deviation.

Return

`StandardDeviation` - The new `StandardDeviation` indicator object.

Definition at line 45 of file Indicators/StandardDeviation.cs.

Supported Indicators

Stochastic

Introduction

This indicator computes the Slow Stochastics %K and %D. The Fast Stochastics %K is is computed by (Current Close Price - Lowest Price of given Period) / (Highest Price of given Period - Lowest Price of given Period) multiplied by 100. Once the Fast Stochastics %K is calculated the Slow Stochastic %K is calculated by the average/smoothed price of of the Fast %K with the given period. The Slow Stochastics %D is then derived from the Slow Stochastics %K with the given period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STO Indicator

To create an automatic indicators for `Stochastic` , call the `STO` helper method from the `QCAlgorithm` class. The `STO` method creates a `Stochastic` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class StochasticAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sto = self.STO(self.symbol, 20, 10, 20)

    def OnData(self, slice: Slice) -> None:
        if self.sto.IsReady:
            # The current value of self.sto is represented by self.sto.Current.Value
            self.Plot("Stochastic", "sto", self.sto.Current.Value)
            # Plot all attributes of self.sto
            self.Plot("Stochastic", "faststoch", self.sto.FastStoch.Current.Value)
            self.Plot("Stochastic", "stochk", self.sto.StochK.Current.Value)
            self.Plot("Stochastic", "stochd", self.sto.StochD.Current.Value)
```

The following reference table describes the `STO` method:

INDICATORS

STO() 1/2

```
Stochastic QuantConnect.Algorithm.QCAlgorithm.STO (
Symbol symbol,
Int32 period,
Int32 kPeriod,
Int32 dPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new Stochastic indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose stochastic we seek.
`Int32`	period	The period of the stochastic. Normally 14.
`Int32`	kPeriod	The sum period of the stochastic. Normally 14.
`Int32`	dPeriod	The sum period of the stochastic. Normally 3.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`Stochastic` - Stochastic indicator for the requested symbol.

Definition at line 1607 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

STO() 2/2

```
Stochastic QuantConnect.Algorithm.QCAlgorithm.STO (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Overload short hand to create a new Stochastic indicator; defaulting to the 3 period for dStoch.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose stochastic we seek.
`Int32`	period	The period of the stochastic. Normally 14.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`Stochastic` - Stochastic indicator for the requested symbol.

Definition at line 1626 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Stochastic` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class StochasticAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sto = Stochastic(20, 10, 20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.sto.Update(bar)

        if self.sto.IsReady:
            # The current value of self.sto is represented by self.sto.Current.Value
            self.Plot("Stochastic", "sto", self.sto.Current.Value)
            # Plot all attributes of self.sto
            self.Plot("Stochastic", "faststoch", self.sto.FastStoch.Current.Value)
            self.Plot("Stochastic", "stochk", self.sto.StochK.Current.Value)
            self.Plot("Stochastic", "stochd", self.sto.StochD.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class StochasticAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sto = Stochastic(20, 10, 20)
        self.RegisterIndicator(self.symbol, self.sto, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.sto.IsReady:
            # The current value of self.sto is represented by self.sto.Current.Value
            self.Plot("Stochastic", "sto", self.sto.Current.Value)
            # Plot all attributes of self.sto
            self.Plot("Stochastic", "faststoch", self.sto.FastStoch.Current.Value)
            self.Plot("Stochastic", "stochk", self.sto.StochK.Current.Value)
            self.Plot("Stochastic", "stochd", self.sto.StochD.Current.Value)
```

The following reference table describes the `Stochastic` constructor:

INDICATORS

Stochastic() 1/2

```
Stochastic QuantConnect.Indicators.Stochastic (
string name,
int period,
int kPeriod,
int dPeriod
)
```

Creates a new Stochastics Indicator from the specified periods.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period given to calculate the Fast %K.
int	kPeriod	The K period given to calculated the Slow %K.
int	dPeriod	The D period given to calculated the Slow %D.

Return

`Stochastic` - The new `Stochastic` indicator object.

Definition at line 56 of file Indicators/Stochastics.cs.

INDICATORS

Stochastic() 2/2

```
Stochastic QuantConnect.Indicators.Stochastic (
int period,
int kPeriod,
int dPeriod
)
```

Creates a new `Stochasti` indicator from the specified inputs.

Show Details

Parameters		
`int`	period	The period given to calculate the Fast %K.
`int`	kPeriod	The K period given to calculated the Slow %K.
`int`	dPeriod	The D period given to calculated the Slow %D.

Return

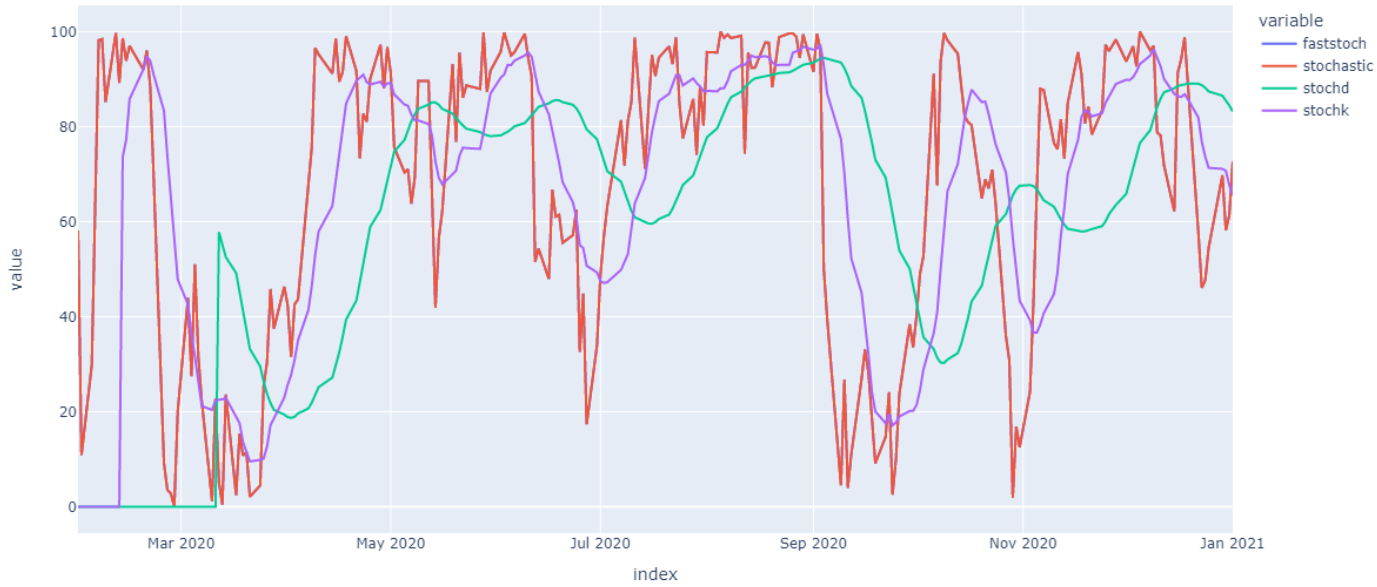
`Stochastic` - The new `Stochastic` indicator object.

Definition at line 92 of file Indicators/Stochastics.cs.

Visualization

The following image shows plot values of selected properties of `Stochastic` using the plotly library.

STO("SPY", 20, 10, 20)



Supported Indicators

Sum

Introduction

This indicator represents an indicator capable of tracking the sum for the given period

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SUM Indicator

To create an automatic indicators for `Sum` , call the `SUM` helper method from the `QCAlgorithm` class. The `SUM` method creates a `Sum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class SumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sum = self.SUM(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.sum.IsReady:
            # The current value of self.sum is represented by self.sum.Current.Value
            self.Plot("Sum", "sum", self.sum.Current.Value)
```

The following reference table describes the `SUM` method:

INDICATORS

SUM() 1/1

```
Sum QuantConnect.Algorithm.QCAlgorithm.SUM (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Sum indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Sum we want.
`Int32`	period	The period over which to compute the Sum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`Sum` - The Sum indicator for the requested symbol over the specified period.

Definition at line 1640 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Sum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class SumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sum = Sum(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.sum.Update(bar.EndTime, bar.Close)

        if self.sum.IsReady:
            # The current value of self.sum is represented by self.sum.Current.Value
            self.Plot("Sum", "sum", self.sum.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class SumAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.sum = Sum(20)
        self.RegisterIndicator(self.symbol, self.sum, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.sum.IsReady:
            # The current value of self.sum is represented by self.sum.Current.Value
            self.Plot("Sum", "sum", self.sum.Current.Value)
```

The following reference table describes the `Sum` constructor:

INDICATORS

Sum() 1/2

```
Sum QuantConnect.Indicators.Sum (
string name,
int period
)
```

Initializes a new instance of the Sum class with the specified name and period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the SMA.

Return

`Sum` - The new `Sum` indicator object.

Definition at line 47 of file Indicators/Sum.cs.

INDICATORS

Sum() 2/2

```
Sum QuantConnect.Indicators.Sum (
int period
)
```

Initializes a new instance of the Sum class with the default name and period.

Show Details

Parameters		
`int`	period	The period of the SMA.

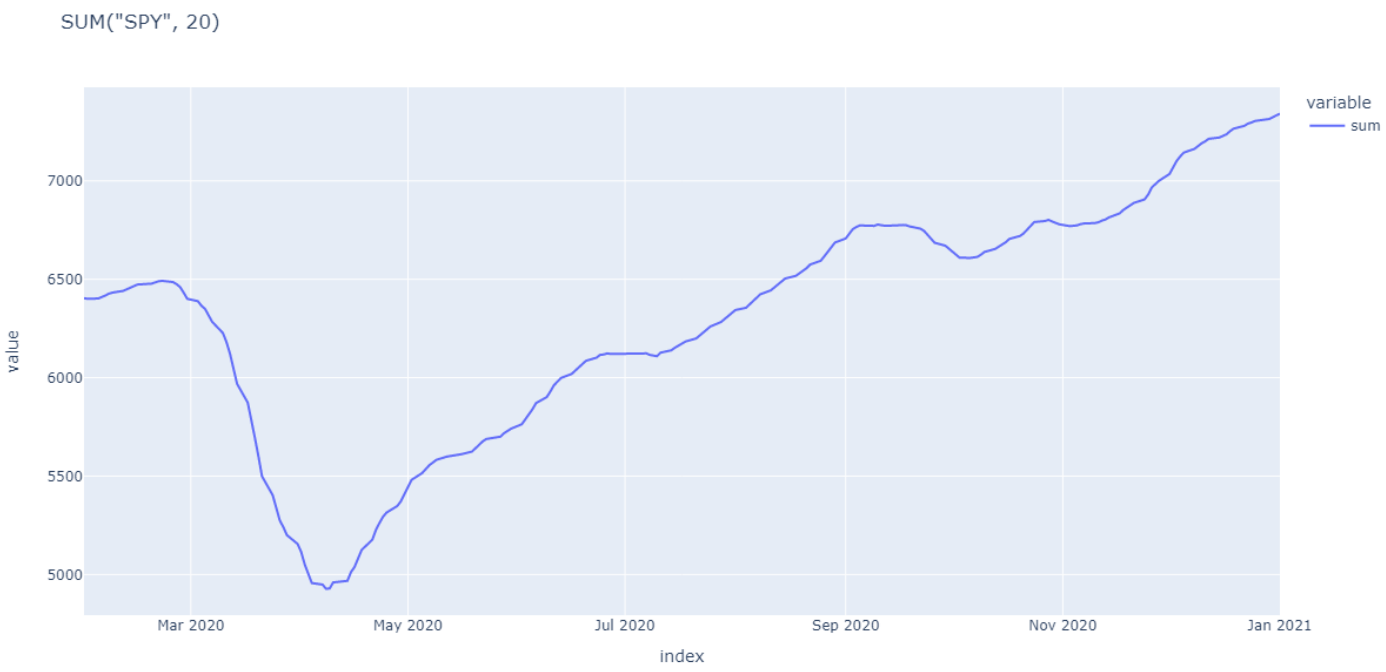
Return

`Sum` - The new `Sum` indicator object.

Definition at line 56 of file Indicators/Sum.cs.

Visualization

The following image shows plot values of selected properties of `Sum` using the plotly library.



Supported Indicators

Super Trend

Introduction

Super trend indicator. Formula can be found here via the excel file: https://tradingtuitions.com/supertrend-indicator-excel-sheet-with-realtime-buy-sell-signals/

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STR Indicator

To create an automatic indicators for `SuperTrend` , call the `STR` helper method from the `QCAlgorithm` class. The `STR` method creates a `SuperTrend` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class SuperTrendAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.str = self.STR(self.symbol, 20, 2, MovingAverageType.Wilders)

    def OnData(self, slice: Slice) -> None:
        if self.str.IsReady:
            # The current value of self.str is represented by self.str.Current.Value
            self.Plot("SuperTrend", "str", self.str.Current.Value)
            # Plot all attributes of self.str
            self.Plot("SuperTrend", "basicupperband", self.str.BasicUpperBand.Current.Value)
            self.Plot("SuperTrend", "basiclowerband", self.str.BasicLowerBand.Current.Value)
            self.Plot("SuperTrend", "currenttrailingupperband",
self.str.CurrentTrailingUpperBand.Current.Value)
            self.Plot("SuperTrend", "currenttrailinglowerband",
self.str.CurrentTrailingLowerBand.Current.Value)
```

The following reference table describes the `STR` method:

INDICATORS

STR() 1/1

```
SuperTrend QuantConnect.Algorithm.QCAlgorithm.STR (
Symbol symbol,
Int32 period,
Decimal multiplier,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new SuperTrend indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose SuperTrend indicator we want.
`Int32`	period	The smoothing period for average True range.
`Decimal`	multiplier	Multiplier to calculate basic upper and lower bands width.
`*MovingAverageType`	movingAverageType	*(Optional)* Smoother type for average True range, defaults to Wilders.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`SuperTrend` - The new `SuperTrend` object.

Definition at line 1469 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `SuperTrend` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

```py
class SuperTrendAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.str = SuperTrend(20, 2, MovingAverageType.Wilders)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.str.Update(bar)

        if self.str.IsReady:
            # The current value of self.str is represented by self.str.Current.Value
            self.Plot("SuperTrend", "str", self.str.Current.Value)
            # Plot all attributes of self.str
            self.Plot("SuperTrend", "basicupperband", self.str.BasicUpperBand.Current.Value)
            self.Plot("SuperTrend", "basiclowerband", self.str.BasicLowerBand.Current.Value)
            self.Plot("SuperTrend", "currenttrailingupperband",
self.str.CurrentTrailingUpperBand.Current.Value)
            self.Plot("SuperTrend", "currenttrailinglowerband",
self.str.CurrentTrailingLowerBand.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class SuperTrendAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.str = SuperTrend(20, 2, MovingAverageType.Wilders)
        self.RegisterIndicator(self.symbol, self.str, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.str.IsReady:
            # The current value of self.str is represented by self.str.Current.Value
            self.Plot("SuperTrend", "str", self.str.Current.Value)
            # Plot all attributes of self.str
            self.Plot("SuperTrend", "basicupperband", self.str.BasicUpperBand.Current.Value)
            self.Plot("SuperTrend", "basiclowerband", self.str.BasicLowerBand.Current.Value)
            self.Plot("SuperTrend", "currenttrailingupperband",
self.str.CurrentTrailingUpperBand.Current.Value)
            self.Plot("SuperTrend", "currenttrailinglowerband",
self.str.CurrentTrailingLowerBand.Current.Value)
```

The following reference table describes the `SuperTrend` constructor:

INDICATORS

SuperTrend() 1/2

```
SuperTrend QuantConnect.Indicators.SuperTrend (
string name,
int period,
decimal multiplier,
*MovingAverageType movingAverageType
)
```

Creates a new SuperTrend indicator using the specified name, period, multiplier and moving average type.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The smoothing period used by average true range.
decimal	multiplier	The coefficient used in calculations of basic upper and lower bands.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of smoothing used to smooth the true range values. Default: MovingAverageType.Wilders.

Return

SuperTrend - The new SuperTrend indicator object.

Definition at line 78 of file Indicators/SuperTrend.cs.

INDICATORS

SuperTrend() 2/2

```
SuperTrend QuantConnect.Indicators.SuperTrend (
int period,
decimal multiplier,
*MovingAverageType movingAverageType
)
```

Creates a new SuperTrend indicator using the specified period, multiplier and moving average type.

Show Details

Parameters		
int	period	The smoothing period used in average true range.
decimal	multiplier	The coefficient used in calculations of basic upper and lower bands.
*MovingAverageType	movingAverageType	*(Optional) (Optional)* The type of smoothing used to smooth the true range values. Default: MovingAverageType.Wilders.

Return

SuperTrend - The new SuperTrend indicator object.

Swiss Army Knife

Introduction

Swiss Army Knife indicator by John Ehlers

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SWISS Indicator

To create an automatic indicators for `SwissArmyKnife` , call the `SWISS` helper method from the `QCAlgorithm` class. The `SWISS` method creates a `SwissArmyKnife` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class SwissArmyKnifeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.swiss = self.SWISS(self.symbol, 20, 0.2, SwissArmyKnifeTool.Gauss)

    def OnData(self, slice: Slice) -> None:
        if self.swiss.IsReady:
            # The current value of self.swiss is represented by self.swiss.Current.Value
            self.Plot("SwissArmyKnife", "swiss", self.swiss.Current.Value)
```

The following reference table describes the `SWISS` method:

INDICATORS

SWISS() 1/1

```
SwissArmyKnife QuantConnect.Algorithm.QCAlgorithm.SWISS (
Symbol symbol,
Int32 period,
Double delta,
SwissArmyKnifeTool tool,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates Swiss Army Knife transformation for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol to use for calculations.
`Int32`	period	The period of the calculation.
`Double`	delta	The delta scale of the BandStop or BandPass.
`SwissArmyKnifeTool`	tool	The tool os the Swiss Army Knife. *Options: ['Gauss', 'Butter', 'HighPass', 'TwoPoleHighPass', 'BandPass']*
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* elects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`SwissArmyKnife` - The calculation using the given tool.

Definition at line 1661 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `SwissArmyKnife` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

T3 Moving Average

Introduction

This indicator computes the T3 Moving Average (T3). The T3 Moving Average is calculated with the following formula: EMA1(x, Period) = EMA(x, Period) EMA2(x, Period) = EMA(EMA1(x, Period),Period) GD(x, Period, volumeFactor) = (EMA1(x, Period)*(1+volumeFactor)) - (EMA2(x, Period)* volumeFactor) T3 = GD(GD(GD(t, Period, volumeFactor), Period, volumeFactor), Period, volumeFactor);

To view the implementation of this indicator, see the LEAN GitHub repository .

Using T3 Indicator

To create an automatic indicators for `T3MovingAverage` , call the `T3` helper method from the `QCAlgorithm` class. The `T3` method creates a `T3MovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class T3MovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.t3 = self.T3(self.symbol, 30, 0.7)

    def OnData(self, slice: Slice) -> None:
        if self.t3.IsReady:
            # The current value of self.t3 is represented by self.t3.Current.Value
            self.Plot("T3MovingAverage", "t3", self.t3.Current.Value)
```

The following reference table describes the `T3` method:

INDICATORS

T3() 1/1

```
T3MovingAverage QuantConnect.Algorithm.QCAlgorithm.T3 (
Symbol symbol,
Int32 period,
*Decimal volumeFactor,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new T3MovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose T3 we want.
`Int32`	period	The period over which to compute the T3.
`*Decimal`	volumeFactor	*(Optional)* The volume factor to be used for the T3 (value must be in the [0,1] range, defaults to 0.7).
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`T3MovingAverage` - The T3MovingAverage indicator for the requested symbol over the specified period.

Definition at line 1680 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `T3MovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class T3MovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.t3 = T3MovingAverage(30, 0.7)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.t3.Update(bar.EndTime, bar.Close)

        if self.t3.IsReady:
            # The current value of self.t3 is represented by self.t3.Current.Value
            self.Plot("T3MovingAverage", "t3", self.t3.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class T3MovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.t3 = T3MovingAverage(30, 0.7)
        self.RegisterIndicator(self.symbol, self.t3, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.t3.IsReady:
            # The current value of self.t3 is represented by self.t3.Current.Value
            self.Plot("T3MovingAverage", "t3", self.t3.Current.Value)
```

The following reference table describes the `T3MovingAverage` constructor:

INDICATORS

T3MovingAverage() 1/2

```
T3MovingAverage QuantConnect.Indicators.T3MovingAverage (
string name,
int period,
*decimal volumeFactor
)
```

Initializes a new instance of the `T3MovingAverag` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the T3MovingAverage.
`*decimal`	volumeFactor	*(Optional) (Optional)* The volume factor of the T3MovingAverage (value must be in the [0,1] range, defaults to 0.7). Default: 0.7m.

Return

`T3MovingAverage` - The new `T3MovingAverage` indicator object.

Definition at line 39 of file Indicators/T3MovingAverage.cs.

INDICATORS

T3MovingAverage() 2/2

```
T3MovingAverage QuantConnect.Indicators.T3MovingAverage (
int period,
*decimal volumeFactor
)
```

Initializes a new instance of the `T3MovingAverag` class using the specified period.

Show Details

Parameters		
`int`	period	The period of the T3MovingAverage.
`*decimal`	volumeFactor	*(Optional) (Optional)* The volume factor of the T3MovingAverage (value must be in the [0,1] range, defaults to 0.7). Default: 0.7m.

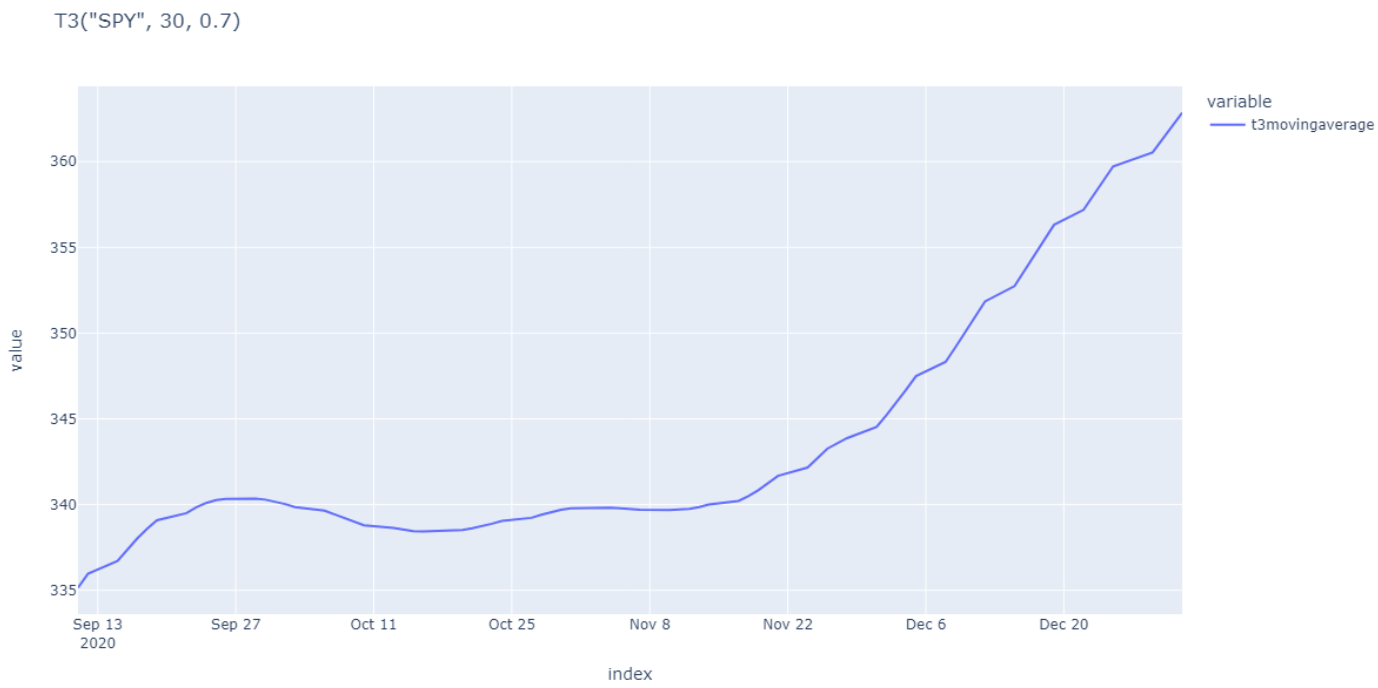
Return

`T3MovingAverage` - The new `T3MovingAverage` indicator object.

Definition at line 53 of file Indicators/T3MovingAverage.cs.

Visualization

The following image shows plot values of selected properties of `T3MovingAverage` using the plotly library.



Supported Indicators

Target Downside Deviation

Introduction

This indicator computes the n-period target downside deviation. The target downside deviation is defined as the root-mean-square, or RMS, of the deviations of the realized return's underperformance from the target return where all returns above the target return are treated as underperformance of 0. Reference: https://www.cmegroup.com/education/files/rr-sortino-a-sharper-ratio.pdf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TDD Indicator

To create an automatic indicators for `TargetDownsideDeviation` , call the `TDD` helper method from the `QCAlgorithm` class. The `TDD` method creates a `TargetDownsideDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class TargetDownsideDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tdd = self.TDD(self.symbol, 50)

    def OnData(self, slice: Slice) -> None:
        if self.tdd.IsReady:
            # The current value of self.tdd is represented by self.tdd.Current.Value
            self.Plot("TargetDownsideDeviation", "tdd", self.tdd.Current.Value)
```

The following reference table describes the `TDD` method:

INDICATORS

TDD() 1/1

```
TargetDownsideDeviation QuantConnect.Algorithm.QCAlgorithm.TDD (
Symbol symbol,
Int32 period,
*Double minimumAcceptableReturn,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new TargetDownsideDeviation indicator. The target downside deviation is defined as the root-mean-square, or RMS, of the deviations of the realized return's underperformance from the target return where all

returns above the target return are treated as underperformance of 0.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TDD we want.
`Int32`	period	The period over which to compute the TDD.
`*Double`	minimumAcceptableReturn	*(Optional)* Minimum acceptable return (MAR) for the target downside deviation calculation.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`TargetDownsideDeviation` - The TargetDownsideDeviation indicator for the requested symbol over the specified period.

Definition at line 1587 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `TargetDownsideDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class TargetDownsideDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tdd = TargetDownsideDeviation(TargetDownsideDeviation(50), RateOfChange(1))

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.tdd.Update(bar.EndTime, bar.Close)

        if self.tdd.IsReady:
            # The current value of self.tdd is represented by self.tdd.Current.Value
            self.Plot("TargetDownsideDeviation", "tdd", self.tdd.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class TargetDownsideDeviationAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tdd = TargetDownsideDeviation(TargetDownsideDeviation(50), RateOfChange(1))
        self.RegisterIndicator(self.symbol, self.tdd, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.tdd.IsReady:
            # The current value of self.tdd is represented by self.tdd.Current.Value
            self.Plot("TargetDownsideDeviation", "tdd", self.tdd.Current.Value)
```

The following reference table describes the `TargetDownsideDeviation` constructor:

INDICATORS

TargetDownsideDeviation() 1/2

```
TargetDownsideDeviation QuantConnect.Indicators.TargetDownsideDeviation (
int period,
*double minimumAcceptableReturn
)
```

return are treated as underperformance of 0.

Show Details

Parameters		
int	period	The sample size of the target downside deviation.
*double	minimumAcceptableReturn	*(Optional) (Optional)* Minimum acceptable return (MAR) for target downside deviation calculation. Default: 0.

Return

`TargetDownsideDeviation` - The new `TargetDownsideDeviation` indicator object.

Definition at line 45 of file Indicators/TargetDownsideDeviation.cs.

INDICATORS

TargetDownsideDeviation() 2/2

```
TargetDownsideDeviation QuantConnect.Indicators.TargetDownsideDeviation (
string name,
int period,

Supported Indicators

Time Profile

Introduction

This indicator represents an Indicator of the Market Profile with Time Price Opportunity (TPO) mode and its attributes

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TP Indicator

To create an automatic indicators for `TimeProfile` , call the `TP` helper method from the `QCAlgorithm` class. The `TP` method creates a `TimeProfile` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class TimeProfileAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tp = self.TP(self.symbol, 3, 0.70, 0.05)

    def OnData(self, slice: Slice) -> None:
        if self.tp.IsReady:
            # The current value of self.tp is represented by self.tp.Current.Value
            self.Plot("TimeProfile", "tp", self.tp.Current.Value)
            # Plot all attributes of self.tp
            self.Plot("TimeProfile", "volumeperprice", self.tp.VolumePerPrice.Current.Value)
            self.Plot("TimeProfile", "profilehigh", self.tp.ProfileHigh.Current.Value)
            self.Plot("TimeProfile", "profilelow", self.tp.ProfileLow.Current.Value)
            self.Plot("TimeProfile", "pocprice", self.tp.POCPrice.Current.Value)
            self.Plot("TimeProfile", "pocvolume", self.tp.POCVolume.Current.Value)
            self.Plot("TimeProfile", "valueareavolume", self.tp.ValueAreaVolume.Current.Value)
            self.Plot("TimeProfile", "valueareahigh", self.tp.ValueAreaHigh.Current.Value)
            self.Plot("TimeProfile", "valuearealow", self.tp.ValueAreaLow.Current.Value)
```

The following reference table describes the `TP` method:

INDICATORS

TP() 1/1

```
TimeProfile QuantConnect.Algorithm.QCAlgorithm.TP (
Symbol symbol,
*Int32 period,
*Decimal valueAreaVolumePercentage,
*Decimal priceRangeRoundOff,
*Resolution resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an Market Profile indicator for the symbol with Time Price Opportunity (TPO) mode. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TP we want.
`*Int32`	period	*(Optional)* The period of the TP.
`*Decimal`	valueAreaVolumePercentage	*(Optional)* The percentage of volume contained in the value area.
`*Decimal`	priceRangeRoundOff	*(Optional)* How many digits you want to round and the precision. i.e 0.01 round to two digits exactly.
`*Resolution`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`TimeProfile` - The Time Profile indicator for the given parameters.

Definition at line 998 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `TimeProfile` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

```py
class TimeProfileAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tp = TimeProfile("", 3, 0.70, 0.05)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.tp.Update(bar)

        if self.tp.IsReady:
            # The current value of self.tp is represented by self.tp.Current.Value
            self.Plot("TimeProfile", "tp", self.tp.Current.Value)
            # Plot all attributes of self.tp
            self.Plot("TimeProfile", "volumeperprice", self.tp.VolumePerPrice.Current.Value)
            self.Plot("TimeProfile", "profilehigh", self.tp.ProfileHigh.Current.Value)
            self.Plot("TimeProfile", "profilelow", self.tp.ProfileLow.Current.Value)
            self.Plot("TimeProfile", "pocprice", self.tp.POCPrice.Current.Value)
            self.Plot("TimeProfile", "pocvolume", self.tp.POCVolume.Current.Value)
            self.Plot("TimeProfile", "valueareavolume", self.tp.ValueAreaVolume.Current.Value)
            self.Plot("TimeProfile", "valueareahigh", self.tp.ValueAreaHigh.Current.Value)
            self.Plot("TimeProfile", "valuearealow", self.tp.ValueAreaLow.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class TimeProfileAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tp = TimeProfile("", 3, 0.70, 0.05)
        self.RegisterIndicator(self.symbol, self.tp, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.tp.IsReady:
            # The current value of self.tp is represented by self.tp.Current.Value
            self.Plot("TimeProfile", "tp", self.tp.Current.Value)
            # Plot all attributes of self.tp
            self.Plot("TimeProfile", "volumeperprice", self.tp.VolumePerPrice.Current.Value)
            self.Plot("TimeProfile", "profilehigh", self.tp.ProfileHigh.Current.Value)
            self.Plot("TimeProfile", "profilelow", self.tp.ProfileLow.Current.Value)
            self.Plot("TimeProfile", "pocprice", self.tp.POCPrice.Current.Value)
            self.Plot("TimeProfile", "pocvolume", self.tp.POCVolume.Current.Value)
            self.Plot("TimeProfile", "valueareavolume", self.tp.ValueAreaVolume.Current.Value)
            self.Plot("TimeProfile", "valueareahigh", self.tp.ValueAreaHigh.Current.Value)
            self.Plot("TimeProfile", "valuearealow", self.tp.ValueAreaLow.Current.Value)
```

The following reference table describes the `TimeProfile` constructor:

INDICATORS

TimeProfile() 1/2

```
TimeProfile QuantConnect.Indicators.TimeProfile (
*int period
)
```

Creates a new TimeProfile indicator with the specified period.

Show Details

Parameters		
*int	period	*(Optional) (Optional)* The period of this indicator. Default: 2.

Return

`TimeProfile` - The new `TimeProfile` indicator object.

Definition at line 29 of file Indicators/TimeProfile.cs.

INDICATORS

TimeProfile() 2/2

```
TimeProfile QuantConnect.Indicators.TimeProfile (
string name,
int period,
*decimal valueAreaVolumePercentage
)
```

Creates a new TimeProfile indicator with the specified name, period and priceRangeRoundOff.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of this indicator.
*decimal	valueAreaVolumePercentage	*(Optional) (Optional)* The percentage of volume contained in the value area. Default: 0.70m.

Return

`TimeProfile` - The new `TimeProfile` indicator object.

Supported Indicators

Triangular Moving Average

Introduction

This indicator computes the Triangular Moving Average (TRIMA). The Triangular Moving Average is calculated with the following formula: (1) When the period is even, TRIMA(x,period)=SMA(SMA(x,period/2),(period/2)+1) (2) When the period is odd, TRIMA(x,period)=SMA(SMA(x,(period+1)/2),(period+1)/2)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIMA Indicator

To create an automatic indicators for `TriangularMovingAverage` , call the `TRIMA` helper method from the `QCAlgorithm` class. The `TRIMA` method creates a `TriangularMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class TriangularMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trima = self.TRIMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.trima.IsReady:
            # The current value of self.trima is represented by self.trima.Current.Value
            self.Plot("TriangularMovingAverage", "trima", self.trima.Current.Value)
```

The following reference table describes the `TRIMA` method:

INDICATORS

TRIMA() 1/1

```
TriangularMovingAverage QuantConnect.Algorithm.QCAlgorithm.TRIMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new TriangularMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TRIMA we want.
`Int32`	period	The period over which to compute the TRIMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`TriangularMovingAverage` - The TriangularMovingAverage indicator for the requested symbol over the specified period.

Definition at line 1756 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `TriangularMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class TriangularMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trima = TriangularMovingAverage(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.trima.Update(bar.EndTime, bar.Close)

        if self.trima.IsReady:
            # The current value of self.trima is represented by self.trima.Current.Value
            self.Plot("TriangularMovingAverage", "trima", self.trima.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class TriangularMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trima = TriangularMovingAverage(20)
        self.RegisterIndicator(self.symbol, self.trima, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.trima.IsReady:
            # The current value of self.trima is represented by self.trima.Current.Value
            self.Plot("TriangularMovingAverage", "trima", self.trima.Current.Value)
```

The following reference table describes the `TriangularMovingAverage` constructor:

INDICATORS

TriangularMovingAverage() 1/2

```
TriangularMovingAverage QuantConnect.Indicators.TriangularMovingAverage (
string name,
int period
)
```

Initializes a new instance of the `TriangularMovingAverag` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the indicator.

Return

`TriangularMovingAverage` - The new `TriangularMovingAverage` indicator object.

Definition at line 35 of file Indicators/TriangularMovingAverage.cs.

INDICATORS

TriangularMovingAverage() 2/2

```
TriangularMovingAverage QuantConnect.Indicators.TriangularMovingAverage (
int period
)
```

Initializes a new instance of the `TriangularMovingAverag` class using the specified period.

Show Details

Parameters		
`int`	period	The period of the indicator.

Supported Indicators

Triple Exponential Moving Average

Introduction

This indicator computes the Triple Exponential Moving Average (TEMA). The Triple Exponential Moving Average is calculated with the following formula: EMA1 = EMA(t,period) EMA2 = EMA(EMA(t,period),period) EMA3 = EMA(EMA(EMA(t,period),period),period) TEMA = 3 * EMA1 - 3 * EMA2 + EMA3

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TEMA Indicator

To create an automatic indicators for `TripleExponentialMovingAverage` , call the `TEMA` helper method from the `QCAlgorithm` class. The `TEMA` method creates a `TripleExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class TripleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tema = self.TEMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.tema.IsReady:
            # The current value of self.tema is represented by self.tema.Current.Value
            self.Plot("TripleExponentialMovingAverage", "tema", self.tema.Current.Value)
```

The following reference table describes the `TEMA` method:

INDICATORS

TEMA() 1/1

```
TripleExponentialMovingAverage QuantConnect.Algorithm.QCAlgorithm.TEMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new TripleExponentialMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TEMA we want.
`Int32`	period	The period over which to compute the TEMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`TripleExponentialMovingAverage` - The TripleExponentialMovingAverage indicator for the requested symbol over the specified period.

Definition at line 1698 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `TripleExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class TripleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tema = TripleExponentialMovingAverage(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.tema.Update(bar.EndTime, bar.Close)

        if self.tema.IsReady:
            # The current value of self.tema is represented by self.tema.Current.Value
            self.Plot("TripleExponentialMovingAverage", "tema", self.tema.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```
class TripleExponentialMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tema = TripleExponentialMovingAverage(20)
        self.RegisterIndicator(self.symbol, self.tema, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.tema.IsReady:
            # The current value of self.tema is represented by self.tema.Current.Value
            self.Plot("TripleExponentialMovingAverage", "tema", self.tema.Current.Value)
```

The following reference table describes the `TripleExponentialMovingAverage` constructor:

INDICATORS

TripleExponentialMovingAverage() 1/2

```
TripleExponentialMovingAverage QuantConnect.Indicators.TripleExponentialMovingAverage (
string name,
int period
)
```

Initializes a new instance of the `TripleExponentialMovingAverag` class using the specified name and period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the TEMA.

Return

`TripleExponentialMovingAverage` - The new `TripleExponentialMovingAverage` indicator object.

Definition at line 38 of file Indicators/TripleExponentialMovingAverage.cs.

INDICATORS

TripleExponentialMovingAverage() 2/2

```
TripleExponentialMovingAverage QuantConnect.Indicators.TripleExponentialMovingAverage (
int period
)
```

Initializes a new instance of the `TripleExponentialMovingAverag` class using the specified period.

Supported Indicators

Trix

Introduction

This indicator computes the TRIX (1-period ROC of a Triple EMA) The TRIX is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:trix

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIX Indicator

To create an automatic indicators for `Trix` , call the `TRIX` helper method from the `QCAlgorithm` class. The `TRIX` method creates a `Trix` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
class TrixAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trix = self.TRIX(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.trix.IsReady:
            # The current value of self.trix is represented by self.trix.Current.Value
            self.Plot("Trix", "trix", self.trix.Current.Value)
```

The following reference table describes the `TRIX` method:

INDICATORS

TRIX() 1/1

```
Trix QuantConnect.Algorithm.QCAlgorithm.TRIX (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Trix indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TRIX we want.
`Int32`	period	The period over which to compute the TRIX.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`Trix` - The Trix indicator for the requested symbol over the specified period.

Definition at line 1774 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Trix` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class TrixAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trix = Trix(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.trix.Update(bar.EndTime, bar.Close)

        if self.trix.IsReady:
            # The current value of self.trix is represented by self.trix.Current.Value
            self.Plot("Trix", "trix", self.trix.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class TrixAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.trix = Trix(20)
        self.RegisterIndicator(self.symbol, self.trix, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.trix.IsReady:
            # The current value of self.trix is represented by self.trix.Current.Value
            self.Plot("Trix", "trix", self.trix.Current.Value)
```

The following reference table describes the `Trix` constructor:

INDICATORS

Trix() 1/2

```
Trix QuantConnect.Indicators.Trix (
string name,
int period
)
```

Initializes a new instance of the `Tri` class using the specified name and period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the indicator.

Return

`Trix` - The new `Trix` indicator object.

Definition at line 36 of file Indicators/Trix.cs.

INDICATORS

Trix() 2/2

```
Trix QuantConnect.Indicators.Trix (
int period
)
```

Initializes a new instance of the `Tri` class using the specified period.

Show Details

Parameters		
`int`	period	The period of the indicator.

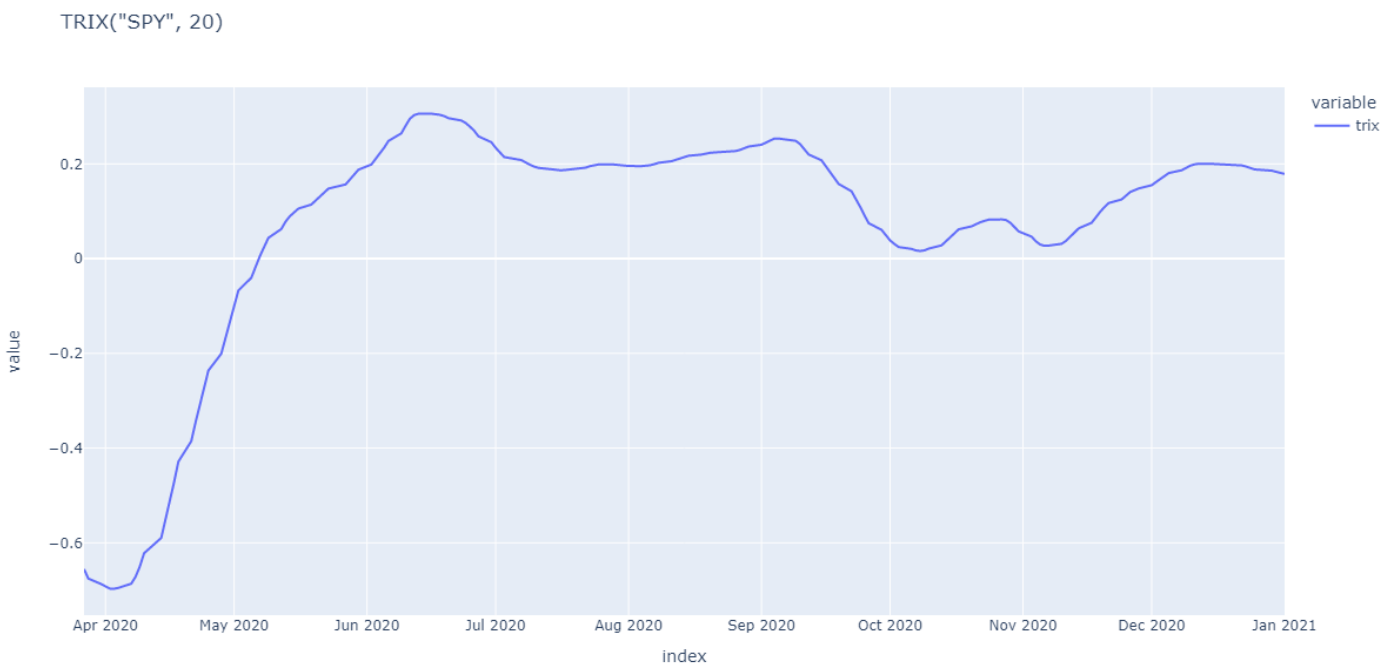
Return

`Trix` - The new `Trix` indicator object.

Definition at line 50 of file Indicators/Trix.cs.

Visualization

The following image shows plot values of selected properties of `Trix` using the plotly library.



Supported Indicators

True Range

Introduction

This indicator computes the True Range (TR). The True Range is the greatest of the following values: value1 = distance from today's high to today's low. value2 = distance from yesterday's close to today's high. value3 = distance from yesterday's close to today's low.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TR Indicator

To create an automatic indicators for `TrueRange` , call the `TR` helper method from the `QCAlgorithm` class. The `TR` method creates a `TrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class TrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tr = self.TR(self.symbol)

    def OnData(self, slice: Slice) -> None:
        if self.tr.IsReady:
            # The current value of self.tr is represented by self.tr.Current.Value
            self.Plot("TrueRange", "tr", self.tr.Current.Value)
```

The following reference table describes the `TR` method:

INDICATORS

TR() 1/1

```
TrueRange QuantConnect.Algorithm.QCAlgorithm.TR (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new TrueRange indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TR we want.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`TrueRange` - The TrueRange indicator for the requested symbol.

Definition at line 1738 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `TrueRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class TrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tr = TrueRange()

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.tr.Update(bar)

        if self.tr.IsReady:
            # The current value of self.tr is represented by self.tr.Current.Value
            self.Plot("TrueRange", "tr", self.tr.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class TrueRangeAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tr = TrueRange()
        self.RegisterIndicator(self.symbol, self.tr, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.tr.IsReady:
            # The current value of self.tr is represented by self.tr.Current.Value
            self.Plot("TrueRange", "tr", self.tr.Current.Value)
```

The following reference table describes the `TrueRange` constructor:

INDICATORS

TrueRange() 1/2

```
TrueRange QuantConnect.Indicators.TrueRange (

)
```

Initializes a new instance of the `TrueRang` class using the specified name.

Show Details

This method requires no argument input.

Return

`TrueRange` - The new `TrueRange` indicator object.

Definition at line 35 of file Indicators/TrueRange.cs.

INDICATORS

TrueRange() 2/2

```
TrueRange QuantConnect.Indicators.TrueRange (
string name
)
```

Initializes a new instance of the `TrueRang` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.

Return

`TrueRange` - The new `TrueRange` indicator object.

Definition at line 44 of file Indicators/TrueRange.cs.

Supported Indicators

True Strength Index

Introduction

This indicator computes the True Strength Index (TSI). The True Strength Index is calculated as explained here: https://school.stockcharts.com/doku.php?id=technical_indicators:True_strength_index Briefly, the calculation has three steps: 1. Smooth the momentum and the absolute momentum by getting an EMA of them (typically of period 25) 2. Double smooth the momentum and the absolute momentum by getting an EMA of their EMA (typically of period 13) 3. The TSI formula itself: divide the double-smoothed momentum over the double-smoothed absolute momentum and multiply by 100 The signal is typically a 7-to-12-EMA of the TSI.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TSI Indicator

To create an automatic indicators for `TrueStrengthIndex` , call the `TSI` helper method from the `QCAlgorithm` class. The `TSI` method creates a `TrueStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class TrueStrengthIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tsi = self.TSI(self.symbol, 25, 13, 7, MovingAverageType.Exponential)

    def OnData(self, slice: Slice) -> None:
        if self.tsi.IsReady:
            # The current value of self.tsi is represented by self.tsi.Current.Value
            self.Plot("TrueStrengthIndex", "tsi", self.tsi.Current.Value)
            # Plot all attributes of self.tsi
            self.Plot("TrueStrengthIndex", "signal", self.tsi.Signal.Current.Value)
```

The following reference table describes the `TSI` method:

INDICATORS

TSI() 1/1

```
TrueStrengthIndex QuantConnect.Algorithm.QCAlgorithm.TSI (
Symbol symbol,
*Int32 longTermPeriod,
*Int32 shortTermPeriod,
*Int32 signalPeriod,
*MovingAverageType signalType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a TrueStrengthIndex indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TSI we want.
`*Int32`	longTermPeriod	*(Optional)* Period used for the second (double) price change smoothing.
`*Int32`	shortTermPeriod	*(Optional)* Period used for the first price change smoothing.
`*Int32`	signalPeriod	*(Optional)* The signal period.
`*MovingAverageType`	signalType	*(Optional)* The type of moving average to use for the signal.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`TrueStrengthIndex` - The TrueStrengthIndex indicator for the given parameters.

Definition at line 1720 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

The following table describes the `MovingAverageType` enumeration members:

You can manually create a `TrueStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

```py
class TrueStrengthIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tsi = TrueStrengthIndex(25, 13, 7, MovingAverageType.Exponential)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.tsi.Update(bar.EndTime, bar.Close)

        if self.tsi.IsReady:
            # The current value of self.tsi is represented by self.tsi.Current.Value
            self.Plot("TrueStrengthIndex", "tsi", self.tsi.Current.Value)
            # Plot all attributes of self.tsi
            self.Plot("TrueStrengthIndex", "signal", self.tsi.Signal.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class TrueStrengthIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.tsi = TrueStrengthIndex(25, 13, 7, MovingAverageType.Exponential)
        self.RegisterIndicator(self.symbol, self.tsi, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.tsi.IsReady:
            # The current value of self.tsi is represented by self.tsi.Current.Value
            self.Plot("TrueStrengthIndex", "tsi", self.tsi.Current.Value)
            # Plot all attributes of self.tsi
            self.Plot("TrueStrengthIndex", "signal", self.tsi.Signal.Current.Value)
```

The following reference table describes the `TrueStrengthIndex` constructor:

INDICATORS

TrueStrengthIndex() 1/2

```
TrueStrengthIndex QuantConnect.Indicators.TrueStrengthIndex (
*int shortTermPeriod,
*int longTermPeriod,
*int signalPeriod,
*MovingAverageType signalType
)
```

Initializes a new instance of the `TrueStrengthInde` class using the specified short and long term smoothing periods, and the signal period and type.

Show Details

Parameters		
*int	shortTermPeriod	*(Optional) (Optional)* Period used for the first price change smoothing. Default: 13.
*int	longTermPeriod	*(Optional) (Optional)* Period used for the second (double) price change smoothing. Default: 25.
*int	signalPeriod	*(Optional) (Optional)* The signal period. Default: 7.
*MovingAverageType	signalType	*(Optional) (Optional)* The type of moving average to use for the signal. Default: MovingAverageType.Exponential.

Return

`TrueStrengthIndex` - The new `TrueStrengthIndex` indicator object.

Definition at line 67 of file Indicators/TrueStrengthIndex.cs.

INDICATORS

TrueStrengthIndex() 2/2

```
TrueStrengthIndex QuantConnect.Indicators.TrueStrengthIndex (
string name,
*int shortTermPeriod,
*int longTermPeriod,
*int signalPeriod,
*MovingAverageType signalType
)
```

Initializes a new instance of the `TrueStrengthInde` class using the specified name, the short and long term smoothing periods, and the signal period and type.

Show Details

Parameters		
`string`	name	The name of the indicator.
`*int`	shortTermPeriod	*(Optional) (Optional)* Period used for the first price change smoothing. Default: 13.
`*int`	longTermPeriod	*(Optional) (Optional)* Period used for the second (double) price change smoothing. Default: 25.
`*int`	signalPeriod	*(Optional) (Optional)* The signal period. Default: 7.
`*MovingAverageType`	signalType	*(Optional) (Optional)* The type of moving average to use for the signal. Default: MovingAverageType.Exponential.

Return

`TrueStrengthIndex` - The new `TrueStrengthIndex` indicator object.

Ultimate Oscillator

Introduction

This indicator computes the Ultimate Oscillator (ULTOSC) The Ultimate Oscillator is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:ultimate_oscillator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ULTOSC Indicator

To create an automatic indicators for `UltimateOscillator` , call the `ULTOSC` helper method from the `QCAlgorithm` class. The `ULTOSC` method creates a `UltimateOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
PY
class UltimateOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ultosc = self.ULTOSC(self.symbol, 5, 10, 20)

    def OnData(self, slice: Slice) -> None:
        if self.ultosc.IsReady:
            # The current value of self.ultosc is represented by self.ultosc.Current.Value
            self.Plot("UltimateOscillator", "ultosc", self.ultosc.Current.Value)
```

The following reference table describes the `ULTOSC` method:

INDICATORS

ULTOSC() 1/1

```
UltimateOscillator QuantConnect.Algorithm.QCAlgorithm.ULTOSC (
Symbol symbol,
Int32 period1,
Int32 period2,
Int32 period3,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new UltimateOscillator indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ULTOSC we want.
`Int32`	period1	The first period over which to compute the ULTOSC.
`Int32`	period2	The second period over which to compute the ULTOSC.
`Int32`	period3	The third period over which to compute the ULTOSC.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`UltimateOscillator` - The UltimateOscillator indicator for the requested symbol over the specified period.

Definition at line 1794 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `UltimateOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class UltimateOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ultosc = UltimateOscillator(5, 10, 20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.ultosc.Update(bar)

        if self.ultosc.IsReady:
            # The current value of self.ultosc is represented by self.ultosc.Current.Value
            self.Plot("UltimateOscillator", "ultosc", self.ultosc.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class UltimateOscillatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.ultosc = UltimateOscillator(5, 10, 20)
        self.RegisterIndicator(self.symbol, self.ultosc, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.ultosc.IsReady:
            # The current value of self.ultosc is represented by self.ultosc.Current.Value
            self.Plot("UltimateOscillator", "ultosc", self.ultosc.Current.Value)
```

The following reference table describes the `UltimateOscillator` constructor:

INDICATORS

UltimateOscillator() 1/2

```
UltimateOscillator QuantConnect.Indicators.UltimateOscillator (
int period1,
int period2,
int period3
)
```

Initializes a new instance of the `UltimateOscillato` class using the specified parameters.

Show Details

Parameters		
int	period1	The first period.
int	period2	The second period.
int	period3	The third period.

Return

`UltimateOscillator` - The new `UltimateOscillator` indicator object.

Definition at line 44 of file Indicators/UltimateOscillator.cs.

INDICATORS

UltimateOscillator() 2/2

```
UltimateOscillator QuantConnect.Indicators.UltimateOscillator (
 string name,
 int period1,
 int period2,
 int period3
 )
```

Initializes a new instance of the `UltimateOscillato` class using the specified parameters.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period1	The first period.

Supported Indicators

Variance

Introduction

This indicator computes the n-period population variance.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VAR Indicator

To create an automatic indicators for `Variance` , call the `VAR` helper method from the `QCAlgorithm` class. The `VAR` method creates a `Variance` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class VarianceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.var = self.VAR(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.var.IsReady:
            # The current value of self.var is represented by self.var.Current.Value
            self.Plot("Variance", "var", self.var.Current.Value)
```

The following reference table describes the `VAR` method:

INDICATORS

VAR() 1/1

```
Variance QuantConnect.Algorithm.QCAlgorithm.VAR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Variance indicator. This will return the population variance of samples over the specified period.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VAR we want.
`Int32`	period	The period over which to compute the VAR.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`Variance` - The Variance indicator for the requested symbol over the specified period.

Definition at line 1812 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `Variance` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class VarianceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.var = Variance(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.var.Update(bar.EndTime, bar.Close)

        if self.var.IsReady:
            # The current value of self.var is represented by self.var.Current.Value
            self.Plot("Variance", "var", self.var.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class VarianceAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.var = Variance(20)
        self.RegisterIndicator(self.symbol, self.var, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.var.IsReady:
            # The current value of self.var is represented by self.var.Current.Value
            self.Plot("Variance", "var", self.var.Current.Value)
```

The following reference table describes the `Variance` constructor:

INDICATORS

Variance() 1/2

```
Variance QuantConnect.Indicators.Variance (
int period
)
```

Initializes a new instance of the `Varianc` class using the specified period.

Show Details

Parameters		
int	period	The period of the indicator.

Return

`Variance` - The new `Variance` indicator object.

Definition at line 32 of file Indicators/Variance.cs.

INDICATORS

Variance() 2/2

```
Variance QuantConnect.Indicators.Variance (
string name,
int period
)
```

Initializes a new instance of the `Varianc` class using the specified name and period.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The period of the indicator.

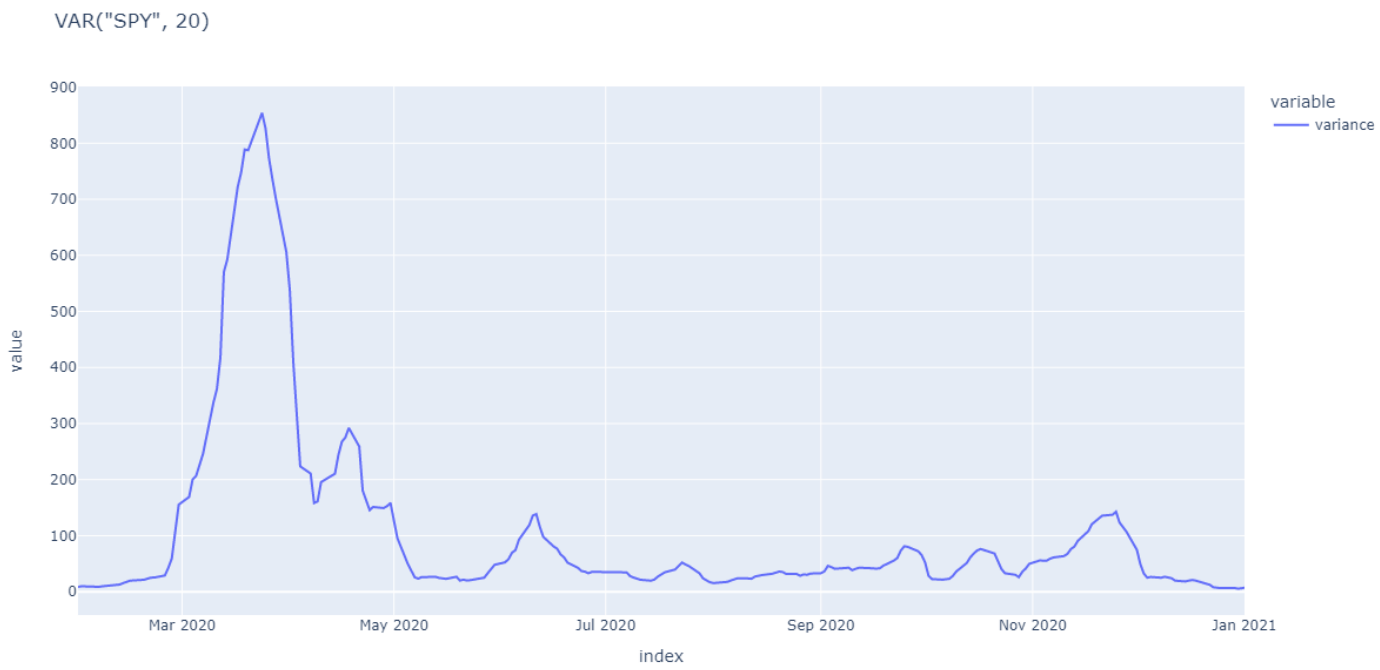
Return

`Variance` - The new `Variance` indicator object.

Definition at line 42 of file Indicators/Variance.cs.

Visualization

The following image shows plot values of selected properties of `Variance` using the plotly library.



Supported Indicators

Volume Profile

Introduction

This indicator represents an Indicator of the Market Profile with Volume Profile mode and its attributes

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VP Indicator

To create an automatic indicators for `VolumeProfile` , call the `VP` helper method from the `QCAlgorithm` class. The `VP` method creates a `VolumeProfile` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class VolumeProfileAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.vp = self.VP(self.symbol, 3, 0.70, 0.05)

    def OnData(self, slice: Slice) -> None:
        if self.vp.IsReady:
            # The current value of self.vp is represented by self.vp.Current.Value
            self.Plot("VolumeProfile", "vp", self.vp.Current.Value)
            # Plot all attributes of self.vp
            self.Plot("VolumeProfile", "volumeperprice", self.vp.VolumePerPrice.Current.Value)
            self.Plot("VolumeProfile", "profilehigh", self.vp.ProfileHigh.Current.Value)
            self.Plot("VolumeProfile", "profilelow", self.vp.ProfileLow.Current.Value)
            self.Plot("VolumeProfile", "pocprice", self.vp.POCPrice.Current.Value)
            self.Plot("VolumeProfile", "pocvolume", self.vp.POCVolume.Current.Value)
            self.Plot("VolumeProfile", "valueareavolume", self.vp.ValueAreaVolume.Current.Value)
            self.Plot("VolumeProfile", "valueareahigh", self.vp.ValueAreaHigh.Current.Value)
            self.Plot("VolumeProfile", "valuearealow", self.vp.ValueAreaLow.Current.Value)
```

The following reference table describes the `VP` method:

INDICATORS

VP() 1/1

```
VolumeProfile QuantConnect.Algorithm.QCAlgorithm.VP (
Symbol symbol,
*Int32 period,
*Decimal valueAreaVolumePercentage,
*Decimal priceRangeRoundOff,
*Resolution resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an Market Profile indicator for the symbol with Volume Profile (VOL) mode. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VP we want.
`*Int32`	period	*(Optional)* The period of the VP.
`*Decimal`	valueAreaVolumePercentage	*(Optional)* The percentage of volume contained in the value area.
`*Decimal`	priceRangeRoundOff	*(Optional)* How many digits you want to round and the precision. i.e 0.01 round to two digits exactly.
`*Resolution`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`VolumeProfile` - The Volume Profile indicator for the given parameters.

Definition at line 977 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `VolumeProfile` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

```py
class VolumeProfileAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.vp = VolumeProfile("", 3, 0.70, 0.05)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.vp.Update(bar)

        if self.vp.IsReady:
            # The current value of self.vp is represented by self.vp.Current.Value
            self.Plot("VolumeProfile", "vp", self.vp.Current.Value)
            # Plot all attributes of self.vp
            self.Plot("VolumeProfile", "volumeperprice", self.vp.VolumePerPrice.Current.Value)
            self.Plot("VolumeProfile", "profilehigh", self.vp.ProfileHigh.Current.Value)
            self.Plot("VolumeProfile", "profilelow", self.vp.ProfileLow.Current.Value)
            self.Plot("VolumeProfile", "pocprice", self.vp.POCPrice.Current.Value)
            self.Plot("VolumeProfile", "pocvolume", self.vp.POCVolume.Current.Value)
            self.Plot("VolumeProfile", "valueareavolume", self.vp.ValueAreaVolume.Current.Value)
            self.Plot("VolumeProfile", "valueareahigh", self.vp.ValueAreaHigh.Current.Value)
            self.Plot("VolumeProfile", "valuearealow", self.vp.ValueAreaLow.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class VolumeProfileAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.vp = VolumeProfile("", 3, 0.70, 0.05)
        self.RegisterIndicator(self.symbol, self.vp, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.vp.IsReady:
            # The current value of self.vp is represented by self.vp.Current.Value
            self.Plot("VolumeProfile", "vp", self.vp.Current.Value)
            # Plot all attributes of self.vp
            self.Plot("VolumeProfile", "volumeperprice", self.vp.VolumePerPrice.Current.Value)
            self.Plot("VolumeProfile", "profilehigh", self.vp.ProfileHigh.Current.Value)
            self.Plot("VolumeProfile", "profilelow", self.vp.ProfileLow.Current.Value)
            self.Plot("VolumeProfile", "pocprice", self.vp.POCPrice.Current.Value)
            self.Plot("VolumeProfile", "pocvolume", self.vp.POCVolume.Current.Value)
            self.Plot("VolumeProfile", "valueareavolume", self.vp.ValueAreaVolume.Current.Value)
            self.Plot("VolumeProfile", "valueareahigh", self.vp.ValueAreaHigh.Current.Value)
            self.Plot("VolumeProfile", "valuearealow", self.vp.ValueAreaLow.Current.Value)
```

The following reference table describes the `VolumeProfile` constructor:

INDICATORS

VolumeProfile() 1/2

```
VolumeProfile QuantConnect.Indicators.VolumeProfile (
*int period
)
```

Creates a new VolumeProfile indicator with the specified period.

Show Details

Parameters		
*int	period	*(Optional) (Optional)* The period of the indicator. Default: 2.

Return

VolumeProfile - The new VolumeProfile indicator object.

Definition at line 29 of file Indicators/VolumeProfile.cs.

INDICATORS

VolumeProfile() 2/2

```
VolumeProfile QuantConnect.Indicators.VolumeProfile (
string name,
int period,
*decimal valueAreaVolumePercentage
)
```

Creates a new VolumeProfile indicator with the specified name, period and priceRangeRoundOff.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of this indicator.
*decimal	valueAreaVolumePercentage	*(Optional) (Optional)* The percentage of volume contained in the value area. Default: 0.70m.

Return

VolumeProfile - The new VolumeProfile indicator object.

Definition at line 42 of file Indicators/VolumeProfile.cs.

Volume Weighted Average Price Indicator

Introduction

Volume Weighted Average Price (VWAP) Indicator: It is calculated by adding up the dollars traded for every transaction (price multiplied by number of shares traded) and then dividing by the total shares traded for the day.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VWAP Indicator

To create an automatic indicators for `VolumeWeightedAveragePriceIndicator` , call the `VWAP` helper method from the `QCAlgorithm` class. The `VWAP` method creates a `VolumeWeightedAveragePriceIndicator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class VolumeWeightedAveragePriceIndicatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.vwap = self.VWAP(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.vwap.IsReady:
            # The current value of self.vwap is represented by self.vwap.Current.Value
            self.Plot("VolumeWeightedAveragePriceIndicator", "vwap", self.vwap.Current.Value)
```

The following reference table describes the `VWAP` method:

INDICATORS

VWAP() 1/2

```
VolumeWeightedAveragePriceIndicator QuantConnect.Algorithm.QCAlgorithm.VWAP (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an VolumeWeightedAveragePrice (VWAP) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VWAP we want.
`Int32`	period	The period of the VWAP.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`VolumeWeightedAveragePriceIndicator` - The VolumeWeightedAveragePrice for the given parameters.

Definition at line 1831 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

VWAP() 2/2

```
IntradayVwap QuantConnect.Algorithm.QCAlgorithm.VWAP (
 Symbol symbol
)
```

Creates the canonical VWAP indicator that resets each day. The indicator will be automatically updated on the security's configured resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VWAP we want.

Return

`IntradayVwap` - The IntradayVWAP for the specified symbol.

Definition at line 1847 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update

its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `VolumeWeightedAveragePriceIndicator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

```py
class VolumeWeightedAveragePriceIndicatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.vwap = VolumeWeightedAveragePriceIndicator(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.vwap.Update(bar)

        if self.vwap.IsReady:
            # The current value of self.vwap is represented by self.vwap.Current.Value
            self.Plot("VolumeWeightedAveragePriceIndicator", "vwap", self.vwap.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class VolumeWeightedAveragePriceIndicatorAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.vwap = VolumeWeightedAveragePriceIndicator(20)
        self.RegisterIndicator(self.symbol, self.vwap, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.vwap.IsReady:
            # The current value of self.vwap is represented by self.vwap.Current.Value
            self.Plot("VolumeWeightedAveragePriceIndicator", "vwap", self.vwap.Current.Value)
```

The following reference table describes the `VolumeWeightedAveragePriceIndicator` constructor:

INDICATORS

VolumeWeightedAveragePriceIndicator() 1/2

```
VolumeWeightedAveragePriceIndicator QuantConnect.Indicators.VolumeWeightedAveragePriceIndicator (
int period
)
```

Initializes a new instance of the VWAP class with the default name and period.

Show Details

Parameters		
int	period	The period of the VWAP.

Return

`VolumeWeightedAveragePriceIndicator` - The new `VolumeWeightedAveragePriceIndicator` indicator object.

Definition at line 40 of file Indicators/VolumeWeightedAveragePriceIndicator.cs.

INDICATORS

VolumeWeightedAveragePriceIndicator() 2/2

```
VolumeWeightedAveragePriceIndicator QuantConnect.Indicators.VolumeWeightedAveragePriceIndicator (
string name,
int period
)
```

Initializes a new instance of the VWAP class with a given name and period.

Show Details

Parameters		
string	name	string - the name of the indicator.
int	period	The period of the VWAP.

Return

`VolumeWeightedAveragePriceIndicator` - The new `VolumeWeightedAveragePriceIndicator` indicator object.

Wilder Accumulative Swing Index

Introduction

This indicator calculates the Accumulative Swing Index (ASI) as defined by Welles Wilder in his book 'New Concepts in Technical Trading Systems'. $ASI_t = ASI_{t-1} + SI_t$ Where: ASI_{t-1} The for the previous period. SI_t The calculated for the current period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ASI Indicator

To create an automatic indicators for `WilderAccumulativeSwingIndex` , call the `ASI` helper method from the `QCAlgorithm` class. The `ASI` method creates a `WilderAccumulativeSwingIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class WilderAccumulativeSwingIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.asi = self.ASI(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.asi.IsReady:
            # The current value of self.asi is represented by self.asi.Current.Value
            self.Plot("WilderAccumulativeSwingIndex", "asi", self.asi.Current.Value)
```

The following reference table describes the `ASI` method:

INDICATORS

ASI() 1/1

```
WilderAccumulativeSwingIndex QuantConnect.Algorithm.QCAlgorithm.ASI (
Symbol symbol,
Decimal limitMove,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a Wilder Accumulative Swing Index (ASI) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ASI we want.
`Decimal`	limitMove	The maximum daily change in price for the ASI.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`WilderAccumulativeSwingIndex` - The WilderAccumulativeSwingIndex for the given parameters.

Definition at line 1927 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `WilderAccumulativeSwingIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

```py
class WilderAccumulativeSwingIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.asi = WilderAccumulativeSwingIndex(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.asi.Update(bar)

        if self.asi.IsReady:
            # The current value of self.asi is represented by self.asi.Current.Value
            self.Plot("WilderAccumulativeSwingIndex", "asi", self.asi.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class WilderAccumulativeSwingIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.asi = WilderAccumulativeSwingIndex(20)
        self.RegisterIndicator(self.symbol, self.asi, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.asi.IsReady:
            # The current value of self.asi is represented by self.asi.Current.Value
            self.Plot("WilderAccumulativeSwingIndex", "asi", self.asi.Current.Value)
```

The following reference table describes the `WilderAccumulativeSwingIndex` constructor:

INDICATORS

WilderAccumulativeSwingIndex() 1/2

```
WilderAccumulativeSwingIndex QuantConnect.Indicators.WilderAccumulativeSwingIndex (
decimal limitMove
)
```

Initializes a new instance of the `WilderAccumulativeSwingInde` class using the specified name.

Show Details

Parameters		
`decimal`	limitMove	A decimal representing the limit move value for the period.

Return

`WilderAccumulativeSwingIndex` - The new `WilderAccumulativeSwingIndex` indicator object.

Definition at line 56 of file Indicators/WilderAccumulativeSwingIndex.cs.

INDICATORS

WilderAccumulativeSwingIndex() 2/2

```
WilderAccumulativeSwingIndex QuantConnect.Indicators.WilderAccumulativeSwingIndex (
string name,
decimal limitMove
)
```

Initializes a new instance of the `WilderAccumulativeSwingInde` class using the specified name.

Show Details

Parameters		
`string`	name	The name of this indicator.
`decimal`	limitMove	A decimal representing the limit move value for the period.

Return

`WilderAccumulativeSwingIndex` - The new `WilderAccumulativeSwingIndex` indicator object.

Definition at line 66 of file Indicators/WilderAccumulativeSwingIndex.cs.

Supported Indicators

Wilder Moving Average

Introduction

This indicator represents the moving average indicator defined by Welles Wilder in his book: New Concepts in Technical Trading Systems.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using WWMA Indicator

To create an automatic indicators for `WilderMovingAverage` , call the `WWMA` helper method from the `QCAlgorithm` class. The `WWMA` method creates a `WilderMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```py
class WilderMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.wwma = self.WWMA(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.wwma.IsReady:
            # The current value of self.wwma is represented by self.wwma.Current.Value
            self.Plot("WilderMovingAverage", "wwma", self.wwma.Current.Value)
```

The following reference table describes the `WWMA` method:

INDICATORS

WWMA() 1/1

```
WilderMovingAverage QuantConnect.Algorithm.QCAlgorithm.WWMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a WilderMovingAverage indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose WMA we want.
`Int32`	period	The period of the WMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`WilderMovingAverage` - The WilderMovingAverage for the given parameters.

Definition at line 1886 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `WilderMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with time/number pair, or an `IndicatorDataPoint` . The indicator will only be ready after you prime it with enough data.

PY

```
class WilderMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.wwma = WilderMovingAverage(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.wwma.Update(bar.EndTime, bar.Close)

        if self.wwma.IsReady:
            # The current value of self.wwma is represented by self.wwma.Current.Value
            self.Plot("WilderMovingAverage", "wwma", self.wwma.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class WilderMovingAverageAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.wwma = WilderMovingAverage(20)
        self.RegisterIndicator(self.symbol, self.wwma, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.wwma.IsReady:
            # The current value of self.wwma is represented by self.wwma.Current.Value
            self.Plot("WilderMovingAverage", "wwma", self.wwma.Current.Value)
```

The following reference table describes the `WilderMovingAverage` constructor:

INDICATORS

WilderMovingAverage() 1/2

```
WilderMovingAverage QuantConnect.Indicators.WilderMovingAverage (
string name,
int period
)
```

Initializes a new instance of the WilderMovingAverage class with the specified name and period.

Show Details

Parameters		
string	name	The name of this indicator.
int	period	The period of the Wilder Moving Average.

Return

`WilderMovingAverage` - The new `WilderMovingAverage` indicator object.

Definition at line 33 of file Indicators/WilderMovingAverage.cs.

INDICATORS

WilderMovingAverage() 2/2

```
WilderMovingAverage QuantConnect.Indicators.WilderMovingAverage (
int period
)
```

Initializes a new instance of the WilderMovingAverage class with the default name and period.

Show Details

Parameters		
`int`	period	The period of the Wilder Moving Average.

Return

`WilderMovingAverage` - The new `WilderMovingAverage` indicator object.

Wilder Swing Index

Introduction

This indicator calculates the Swing Index (SI) as defined by Welles Wilder in his book 'New Concepts in Technical Trading Systems'. SI_t = 50 * (N / R) * (K / T) Where: N Equals: C_t - C_{t-1} + 0.5 * (C_t - O_t) + 0.25 * (C_{t-1} - O_{t-1}) *See* R Found by selecting the expression with the largest value and then using the corresponding formula. Expression => Formula $|H_t - C_{t-1}|$ => $|H_t - C_t|$ - 0.5 * $|L_t - C_{t-1}|$ + 0.25 * $|C_{t-1} - O_{t-1}|$ $|L_t - C_{t-1}|$ => $|L_t - C_t|$ - 0.5 * $|H_t - C_{t-1}|$ + 0.25 * $|C_{t-1} - O_{t-1}|$ $|H_t - L_t|$ => $|H_t - L_{t-1}|$ + 0.25 * $|C_{t-1} - O_{t-1}|$ *See* K Found by selecting the larger of the two expressions: $|H_t - C_{t-1}|$, $|L_t - C_{t-1}|$ *See* T The limit move, or the maximum change in price during the time period for the bar. Passed as limitMove via the constructor. *See*

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SI Indicator

To create an automatic indicators for `WilderSwingIndex` , call the `SI` helper method from the `QCAlgorithm` class. The `SI` method creates a `WilderSwingIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class WilderSwingIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.si = self.SI(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.si.IsReady:
            # The current value of self.si is represented by self.si.Current.Value
            self.Plot("WilderSwingIndex", "si", self.si.Current.Value)
```

The following reference table describes the `SI` method:

INDICATORS

SI() 1/1

```
WilderSwingIndex QuantConnect.Algorithm.QCAlgorithm.SI (
Symbol symbol,
Decimal limitMove,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a Wilder Swing Index (SI) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose SI we want.
`Decimal`	limitMove	The maximum daily change in price for the SI.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`WilderSwingIndex` - The WilderSwingIndex for the given parameters.

Definition at line 1906 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `WilderSwingIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` . The indicator will only be ready after you prime it with enough data.

```py
class WilderSwingIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.si = WilderSwingIndex(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.si.Update(bar)

        if self.si.IsReady:
            # The current value of self.si is represented by self.si.Current.Value
            self.Plot("WilderSwingIndex", "si", self.si.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

```py
class WilderSwingIndexAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.si = WilderSwingIndex(20)
        self.RegisterIndicator(self.symbol, self.si, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.si.IsReady:
            # The current value of self.si is represented by self.si.Current.Value
            self.Plot("WilderSwingIndex", "si", self.si.Current.Value)
```

The following reference table describes the `WilderSwingIndex` constructor:

INDICATORS

WilderSwingIndex() 1/2

```
WilderSwingIndex QuantConnect.Indicators.WilderSwingIndex (
string name,
decimal limitMove
)
```

Initializes a new instance of the `WilderSwingInde` class using the specified name.

Show Details

Parameters		
`string`	name	A string for the name of this indicator.
`decimal`	limitMove	A decimal representing the limit move value for the period.

Return

`WilderSwingIndex` - The new `WilderSwingIndex` indicator object.

Definition at line 116 of file Indicators/WilderSwingIndex.cs.

INDICATORS

WilderSwingIndex() 2/2

```
WilderSwingIndex QuantConnect.Indicators.WilderSwingIndex (
decimal limitMove
)
```

Initializes a new instance of the `WilderSwingInde` class using the default name.

Show Details

Parameters		
`decimal`	limitMove	A decimal representing the limit move value for the period.

Return

`WilderSwingIndex` - The new `WilderSwingIndex` indicator object.

Definition at line 126 of file Indicators/WilderSwingIndex.cs.

Williams Percent R

Introduction

Williams %R, or just %R, is the current closing price in relation to the high and low of the past N days (for a given N). The value of this indicator fluctuates between -100 and 0. The symbol is said to be oversold when the oscillator is below -80%, and overbought when the oscillator is above -20%.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using WILR Indicator

To create an automatic indicators for `WilliamsPercentR` , call the `WILR` helper method from the `QCAlgorithm` class. The `WILR` method creates a `WilliamsPercentR` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

PY

```
class WilliamsPercentRAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.wilr = self.WILR(self.symbol, 20)

    def OnData(self, slice: Slice) -> None:
        if self.wilr.IsReady:
            # The current value of self.wilr is represented by self.wilr.Current.Value
            self.Plot("WilliamsPercentR", "wilr", self.wilr.Current.Value)
            # Plot all attributes of self.wilr
            self.Plot("WilliamsPercentR", "maximum", self.wilr.Maximum.Current.Value)
            self.Plot("WilliamsPercentR", "minimum", self.wilr.Minimum.Current.Value)
```

The following reference table describes the `WILR` method:

INDICATORS

WILR() 1/1

```
WilliamsPercentR QuantConnect.Algorithm.QCAlgorithm.WILR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Williams %R indicator. This will compute the percentage change of the current closing price in relation to the high and low of the past N periods. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Williams %R we want.
`Int32`	period	The period over which to compute the Williams %R.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`WilliamsPercentR` - The Williams %R indicator for the requested symbol over the specified period.

Definition at line 1866 of file Algorithm/QCAlgorithm.Indicators.cs.

If you don't provide a resolution, it defaults to the security resolution. If you provide a resolution, it must be greater than or equal to the resolution of the security. For instance, if you subscribe to hourly data for a security, you should update its indicator with data that spans 1 hour or longer.

For more information about the selector argument, see Alternative Price Fields .

For more information about plotting indicators, see Plotting Indicators .

You can manually create a `WilliamsPercentR` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method with a `TradeBar` , or `QuoteBar` . The indicator will only be ready after you prime it with enough data.

PY

```
class WilliamsPercentRAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.wilr = WilliamsPercentR(20)

    def OnData(self, slice: Slice) -> None:
        bar = slice.Bars.get(self.symbol)
        if bar:
            self.wilr.Update(bar)

        if self.wilr.IsReady:
            # The current value of self.wilr is represented by self.wilr.Current.Value
            self.Plot("WilliamsPercentR", "wilr", self.wilr.Current.Value)
            # Plot all attributes of self.wilr
            self.Plot("WilliamsPercentR", "maximum", self.wilr.Maximum.Current.Value)
            self.Plot("WilliamsPercentR", "minimum", self.wilr.Minimum.Current.Value)
```

To register a manual indicator for automatic updates with the security data, call the `RegisterIndicator` method.

PY

```
class WilliamsPercentRAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
        self.wilr = WilliamsPercentR(20)
        self.RegisterIndicator(self.symbol, self.wilr, Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        if self.wilr.IsReady:
            # The current value of self.wilr is represented by self.wilr.Current.Value
            self.Plot("WilliamsPercentR", "wilr", self.wilr.Current.Value)
            # Plot all attributes of self.wilr
            self.Plot("WilliamsPercentR", "maximum", self.wilr.Maximum.Current.Value)
            self.Plot("WilliamsPercentR", "minimum", self.wilr.Minimum.Current.Value)
```

The following reference table describes the `WilliamsPercentR` constructor:

INDICATORS

WilliamsPercentR() 1/2

```
WilliamsPercentR QuantConnect.Indicators.WilliamsPercentR (
int period
)
```

Creates a new Williams %R.

Show Details

Parameters		
int	period	The look-back period to determine the Williams %R.

Return

`WilliamsPercentR` - The new `WilliamsPercentR` indicator object.

Definition at line 52 of file Indicators/WilliamsPercentR.cs.

INDICATORS

WilliamsPercentR() 2/2

```
WilliamsPercentR QuantConnect.Indicators.WilliamsPercentR (
string name,
int period
)
```

Creates a new Williams %R.

Show Details

Parameters		
`string`	name	The name of this indicator.
`int`	period	The look-back period to determine the Williams %R.

Return

`WilliamsPercentR` - The new `WilliamsPercentR` indicator object.

Indicators

Key Concepts

Introduction

Indicators translate a stream of data points into a numerical value you can use to detect trading opportunities. LEAN provides more than 100 pre-built technical indicators and candlestick patterns you can use in your algorithms. To view a list of all the indicators, see the Supported Indicators . One simple indicator to learn is the Identity indicator, which just returns the value of the asset.

```
pep = self.Identity("PEP") # Pepsi ticker
```
PY

Design Philosophy

Technical indicators take in a stream of data points, `Bar` objects, or `TradeBar` objects and produce a continuous value. Candlestick patterns take in a stream of `Bar` or `TradeBar` objects and produce a value that's either 0, 1, or -1 to signify the presence of the pattern.

You can configure technical indicators and candlestick patterns to receive manual or automatic updates. With manual indicators, you update the indicator with whatever data you want and whenever you want. With automatic indicators, the algorithm automatically uses the security data to update the indicator value.

LEAN's indicators are implemented "on-line". This means as data pipes through, it updates the internal state of the indicator. Other platforms perform indicator math on an array of values in bulk which can be very inefficient when working on large volumes of data. You need to warm up your indicators and prime them with data to get them ready.

Indicator Types

You can classify an indicator as either a data point, bar, or TradeBar indicator. Their classification depends on the type of data they receive.

Data Point Indicators

Data point indicators use `IndicatorDataPoint` objects to compute their value. Some examples of data point indicators include the following:

- SimpleMovingAverage
- ExponentialMovingAverage
- Momentum

Bar Indicators

Bar indicators use `QuoteBar` or `TradeBar` objects to compute their value. Since Forex and CFD securities don't have `TradeBar` data, they use bar indicators. Candlestick patterns are examples of bar indicators. Some other examples of bar indicators include the following:

- WilliamsPercentR
- Stochastics
- AverageTrueRange

TradeBar Indicators

`TradeBar` indicators use `TradeBar` objects to compute their value. Some `TradeBar` indicators use the volume property of the `TradeBar` to compute their value. Some examples of `TradeBar` indicators include the following:

- Beta
- AdvanceDeclineVolumeRatio
- VolumeWeightedAveragePriceIndicator

Naming Convention

The class name to create a manual indicator is the indicator name spelled in pascal case. For example, to create a manual simple moving average indicator , use the `SimpleMovingAverage` class.

The method to create an automatic indicator is usually named after the acronym of the indicator name. For example, to create an automatic simple moving average indicator , use the `SMA` method.

To view the class name and shortcut method of each indicator, see the Supported Indicators .

Create Indicators

There are two ways to create indicators. You can create indicators with the indicator constructor or use a helper method in the `QCAlgorithm` class. If you use the helper method, the indicator automatically updates as your algorithm receives new data.

```
PY
# Create a manual indicator with the indicator constructor
self.manual_sma = SimpleMovingAverage(20, Resolution.Daily)

# Create an automatic indicator with the helper method
symbol = self.AddCrypto("BTCUSD").Symbol;
auto_sma = self.SMA(symbol, 20, Resolution.Daily)
```

Check Readiness

Indicators aren't always ready when you first create them. The length of time it takes to trust the indicator values depends on the indicator period. To know if an indicator is ready to use, use the `IsReady` property.

```
PY
if not self.indicator.IsReady:
    return
```

To get the number of samples the indicator has processed, use the `Samples` property.

```
PY
samples = self.indicator.Samples
```

Track Update Events

When an indicator receives a new data point and updates its state, it triggers an update event. To be notified of update events, attach an event handler to the indicator object. The event handler receives 2 arguments: the indicator object and the latest `IndicatorDataPoint` it produced.

```py
# After you create the indicator, attach an event handler
self.indicator.Updated += self.update_event_handler

# Define the event handler within the same class
def update_event_handler(self, indicator: object, indicator_data_point: IndicatorDataPoint) -> None:
    if indicator.IsReady:
        self.Plot("Indicator", "Value", indicator_data_point.Value)
```

Get Indicator Values

You can access current and historical indicator values.

Current Indicator Values

To access the indicator value, use the `.Current.Value` property. Some indicators have one output and some indicators have multiple outputs. The `SimpleMovingAverage` indicator only has one output, the average price over the last n periods, so the `.Current.Value` property returns this value. The `BollingerBand` indicator has multiple outputs because it has a simple moving average, an upper band, and a lower band. For indicators that have multiple outputs, refer to the Supported Indicators to see how to access the output values.

```py
sma = self.sma.Current.Value

current_price = self.bb.Current.Value
bb_upper_band = self.bb.UpperBand.Current.Value
bb_lower_band = self.bb.LowerBand.Current.Value
```

You can implicitly cast indicators to the decimal version of their `.Current.Value` property.

```py
if self.sma > self.bb.UpperBand:
    self.SetHoldings(self.symbol, -0.1)
```

Historical Indicator Values

To track historical indicator values, use a `RollingWindow` . Indicators emit an `Updated` event when they update. To create a `RollingWindow` of indicator points, attach an event handler function to the `Updated` member that adds the last value of the indicator to the `RollingWindow` . The value is an `IndicatorDataPoint` object that represents a piece of data at a specific time.

```py
def Initialize(self) -> None:
    # Creates an indicator and adds to a RollingWindow when it is updated
    self.sma_window = RollingWindow[IndicatorDataPoint](5)
    self.SMA("SPY", 5).Updated += (lambda sender, updated: self.sma_window.Add(updated))
```

The current (most recent) indicator value is at index 0, the previous value is at index 1, and so on until the length of the window.

```
current_sma = self.sma_window[0]
previous_sma = self.sma_window[1]
oldest_sma = self.sma_window[sma_window.Count - 1]
```

Reset Indicators

To reset indicators, call the `Reset` method.

```
self.indicator.Reset()
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your indicators when splits and dividends occur. If a split or dividend occurs, the data in your indicators becomes invalid because it doesn't account for the price adjustments that the split or dividend causes. To replace your indicator history with the newly-adjusted prices, call the `Reset` method and then warm up the indicator.

```
# In OnData
if data.Splits.ContainsKey(self.symbol) or data.Dividends.ContainsKey(self.symbol):
    # Reset the indicator
    self.sma.Reset()

    # Warm up the indicator
```

The process to warm up your indicator depends on if it's a manual or automatic indicator .

Common Design Patterns

The location in your algorithm where you create and manage indicators depends on the type of universe in your algorithm.

One Asset In a Static Universe

If you only have one security in your algorithm, you can create an automatic indicator in the `Initialize` method.

```
def Initialize(self):
  self.symbol = self.AddEquity("SPY").Symbol
    self.EnableAutomaticIndicatorWarmUp = True
    self.sma = self.SMA(self.symbol, 20, Resolution.Daily)
```

Multiple Assets or a Dynamic Universe

If your algorithm has multiple assets or a dynamic universe of assets, abstract your indicator management logic into a separate class.

```
class SymbolData:
    def __init__(self, algorithm, symbol):
        self.algorithm = algorithm
        self.symbol = symbol

        # Create an indicator
        self.sma = SimpleMovingAverage(20)

        # Create a consolidator to update the indicator
        self.consolidator = TradeBarConsolidator(1)
        self.consolidator.DataConsolidated += self.OnDataConsolidated

        # Register the consolidator to update the indicator
        algorithm.SubscriptionManager.AddConsolidator(symbol, self.consolidator)

        # Warm up the indicator
        algorithm.WarmUpIndicator(symbol, self.sma)

    def OnDataConsolidated(self, sender: object, consolidated_bar: TradeBar) -> None:
        self.sma.Update(consolidated_bar.EndTime, consolidated_bar.Close)

    # If you have a dynamic universe, remove consolidators for the securities removed from the universe
    def dispose(self) -> None:
        self.algorithm.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

Every time the universe adds or removes a security, create or dispose of the respective `SymbolData` object in the `OnSecuritiesChanged` event handler.

```
class MyAlgorithm(QCAlgorithm):
    symbol_data_by_symbol = {}

    def OnSecuritiesChanged(self, changes: SecurityChanges) -> None:
        for security in changes.AddedSecurities:
            self.symbol_data_by_symbol[security.Symbol] = SymbolData(self, security.Symbol)

        # If you have a dynamic universe, track removed securities
        for security in changes.RemovedSecurities:
            symbol_data = self.symbol_data_by_symbol.pop(security.Symbol, None)
            if symbol_data:
                symbol_data.dispose()
```

Differences From Third-Party Indicators

The values of our indicators can sometimes produce different results than the indicators on other platforms. These discrepancies can be a result of differences in the input data, timestamps, or implementation.

Price Differences

If you find differences in indicator values, compare the prices that are fed into the indicator on each platform. If the input data is slightly different, the indicator values will be different. To test if it's a difference in price data, feed in the data from the third-party platform into our indicators. We validate the indicators against third-party sources and when the values are the same, the indicator values are similar too.

Timestamp Differences

We timestamp our data to the time when the period ends. Many other platforms timestamp to the beginning of the candle.

Implementation Differences

Some indicators can have slightly different default arguments for their implementation. A common difference across platforms is to use a different `MovingAverageType` for the indicators. To view the default arguments for all our indicators, see Supported Indicators . To view the full implementation of our indicators, see the LEAN GitHub repository .

Warm Up Period Differences

Some platforms use all of the historical data to warm up their indicators while LEAN indicators have a fixed number of bars they need to warm up. As a result, indicators with long memory like the Exponential Moving Average can have slightly different values across platforms.

Indicators

Manual Indicators

Introduction

Manual indicators are indicators that don't automatically update from the underlying security data. Manual updates let you customize how you update the indicator and let you use the indicator in dynamic universes without causing your algorithm to slow down over time. It's not always necessary to create manual indicators though. If your algorithm only uses a static universe and you want to update the indicator with data from the security subscription, create an automatic indicator . Automatic indicators are easier to create and update.

Naming Convention

The class name to create a manual indicator is the indicator name spelled in pascal case. For example, to create a manual simple moving average indicator , use the `SimpleMovingAverage` class.

Create Manual Indicators

To create manual indicators, instantiate an indicator with its constructor. To view all of the available indicators and their constructors, see Supported Indicators .

```
PY
# Create an indicator
self.delay = Delay(20)

# Create a candlestick pattern
self.two_crows = TwoCrows()
```

You can track indicators by their name. To name a manual indicator, pass a string as the first argument to the constructor.

```
PY
# Name an indicator
self.delay = Delay("AAPL Past Price", 20)
self.Log(self.delay.Name)

# Name a candlestick pattern
self.two_crows = TwoCrows("Two Crows Pattern")
self.Log(self.two_crows.Name)
```

If you don't name an indicator, it's given a default name. For example, the default name for a `Delay` indicator is "Delay(period)".

Manual Updates

With manual updates, you control what data you use to update the indicator. For instance, you can use the 3:30 PM price in your daily moving average instead of the daily closing price or you can use the maximum temperature of the past 10 cloudy days.

To update an indicator, call the `Update` method. The `Update` method expects one of the following arguments:

- Time/decimal pair
- `IndicatorDataPoint`
- `QuoteBar`
- `TradeBar`
- Custom data bar

To view what data type you should use to update an indicator, see Supported Indicators .

You can update indicators at any point in your algorithm, but the most common places are during the `OnData` event handler or during a consolidation event handler.

```py
def Initialize(self) -> None:
    self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol

    self.rsi = RelativeStrengthIndex(10, MovingAverageType.Simple)
    self.ad = AccumulationDistribution()

    self.consolidator = TradeBarConsolidator(timedelta(days=3))
    # Update the AD indicator with the consolidated bar
    self.consolidator.DataConsolidated += (lambda _, bar : self.ad.Update(bar))
    self.SubscriptionManager.AddConsolidator(self.symbol, self.consolidator)

def OnData(self, slice: Slice) -> None:
    # Update the RSI indicator value with the new input close price every day
    if slice.Bars.ContainsKey(self.symbol):
        bar = slice.Bars[self.symbol]
        self.rsi.Update(bar.EndTime, bar.Close)
```

Automatic Updates

With automatic updates, your indicators automatically update with the security data on a schedule you set. To configure automatic updates, create a consolidator and then call the `RegisterIndicator` method. If your algorithm has a dynamic universe, save a reference to the consolidator so you can remove it when the universe removes the security. If you register an indicator for automatic updates, don't call the indicator's `Update` method or else the indicator will receive double updates.

```py
# Create a security subscription
self.symbol = self.AddEquity("SPY", Resolution.Minute).Symbol

# Create a manual indicator
self.indicator = RelativeStrengthIndex(10, MovingAverageType.Simple)

# Create a consolidator
self.consolidator = TradeBarConsolidator(1)

# Register the indicator to update with the consolidated data
self.RegisterIndicator(self.symbol, self.indicator, self.consolidator)
```

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with `TradeBar` data, that price is the `TradeBar` close price. For assets with `QuoteBar` data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the `Open` , `High` , `Low` , or `Close` , provide a `selector` argument to the `RegisterIndicator` method.

```
self.RegisterIndicator(self.symbol, self.indicator, self.consolidator, Field.High)
```

The `Field` class has the following `selector` properties:

Warm Up Indicators

Indicators use historical data to compute their value. Before you start trading with an indicator, warm it up. There are several ways to warm-up manual indicators.

Manual Indicator Warm-up

If you have access to the `QCAlgorithm` object, you can manually warmup indicators with a history request .

```
self.sma = SimpleMovingAverage(20)
history = algorithm.History(self.symbol, 20, Resolution.Daily)
if not history.empty:
    for time, row in history.loc[self.symbol].iterrows():
        self.sma.Update(time, row.close)
```

Warm-up Helper Method

If an indicator inherits the `IIndicatorWarmUpPeriodProvider` class, you can warm it up with the `WarmUpIndicator` method.

```
self.sma = SimpleMovingAverage(20)
algorithm.WarmUpIndicator(self.symbol, self.sma)
```

To warm up the indicator with a resolution that's different from the security resolution, pass a resolution or `timedelta` argument to the `WarmUpIndicator` method. The resolution you provide should be greater than or equal to the security resolution. For example, if the security has minute resolution data, you should warm up the indicator with data that spans at least one minute.

```
# Warm-up with daily bars
algorithm.WarmUpIndicator(self.symbol, self.sma, Resolution.Daily)

# Warm-up with 3-day bars
algorithm.WarmUpIndicator(self.symbol, self.sma, timedelta(days=3))
```

The `WarmUpIndicator` method uses the default `Value` of the historical data to warm up the indicator. In most cases, this is the closing price. To warm up the indicator with a different data field, pass a `Field` argument to the method.

```
algorithm.WarmUpIndicator(self.symbol, self.sma, Resolution.Daily, Field.High)
```

Algorithm Warm-up

If you create indicators at the beginning of your algorithm, you can set an algorithm warm-up period to warm up the

indicators. When you set an algorithm warm-up period, the engine pumps data in and automatically updates all the indicators from before the start date of the algorithm. To ensure that all the indicators are ready after the algorithm warm-up period, choose a lookback period that contains sufficient data.

```
# In Initialize
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
self.sma = SimpleMovingAverage(20)
self.SetWarmUp(20)

# In OnData
self.sma.Update(data[self.symbol]) # Delete this line if you registered the indicator for automatic
updates
if self.IsWarmingUp:
    return
```

PY

Timing Considerations

In some cases, you might create and warm up the indicator during its sampling period. For example, say the security resolution is minute, the indicator resolution is daily, and you create and warm-up the indicator at noon without using the `SetWarmUp` method. In this example, the history request that gathers data to warm up the indicator won't contain any data from the current day. Furthermore, if you set up a consolidator to update the indicator, the consolidator also won't aggregate any data from before noon. It doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Indicators

Automatic Indicators

Introduction

Automatic indicators are indicators that automatically update from the underlying security data. Automatic indicators do everything that manual indicators do, but with automatic updates registered for you. If you have a dynamic universe, you shouldn't use automatic indicators because you can't remove the consolidator that updates the indicator. Since you can't remove the consolidator, the consolidators build up over time and slow down your algorithm. If your algorithm has a dynamic universe, use manual indicators instead.

Naming Convention

The method to create an automatic indicator is usually named after the acronym of the indicator name. For example, to create an automatic simple moving average indicator , use the `SMA` method.

Create Automatic Indicators

To create automatic indicators, call the indicator helper method from the `QCAlgorithm` class. The indicator helper methods create an indicator object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. To view the helper method for each indicator, see Supported Indicators . In most cases, you should call the helper method in the `Initialize` method.

The indicator resolution must be greater than or equal to the resolution of the security subscription. For instance, if your security subscription is for minute resolution data, the indicator resolution should be minute, hour, or daily resolution.

```
PY
# In Initialize()
symbol = self.AddEquity("SPY").Symbol

#  - Create an indicator
self.sma = self.SMA(symbol, 20, Resolution.Daily)

#  - Create a candlestick pattern
patterns = CandlestickPatterns(self)
self.two_crows = patterns.TwoCrows(self.symbol)
```

When you create an indicator with a helper method, the indicator is given a default name. You can track indicators by their name. The default name for the `SimpleMovingAverage` indicator is "SMA(period , ticker _ resolution)". For example, in the preceding code snippet, the `SimpleMovingAverage` indicator is named "SMA(20,SPY_day)". To get the name of an indicator, inspect its `Name` property.

```
PY
self.Log(self.sma.Name)
self.Log(self.two_crows.Name)
```

Alternative Price Fields

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with `TradeBar` data, that price is the `TradeBar` close price. For assets with `QuoteBar` data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the `Open` , `High` , `Low` , or `Close` , provide a `selector` argument to the indicator helper method.

```
# Define a 10-period daily RSI indicator with shortcut helper method
# Select the Open price to update the indicator
self.rsi = self.RSI("SPY", 10,  MovingAverageType.Simple, Resolution.Daily, Field.Open)
```

The `Field` class has the following `selector` properties:

Warm Up Indicators

Indicators compute their value based on historical data. Before you start trading with an indicator, warm it up. There are several ways to warm-up automatic indicators.

Algorithm Warm-up

You can set an algorithm warm-up period to warm up the indicators. When you set an algorithm warm-up period, the engine pumps data in and automatically updates all the indicators from before the start date. To ensure that all the indicators are ready after the algorithm warm-up period, choose a look-back period that contains sufficient data.

```
# In Initialize
symbol = self.AddEquity("SPY").Symbol
self.sma = self.SMA(symbol, 20, Resolution.Daily)
self.SetWarmUp(20, Resolution.Daily)

# In OnData
if self.IsWarmingUp:
    return
```

Manual Indicator Warm-up

You can manually warm up indicators with a history request .

```
# In Initialize
symbol = self.AddEquity("SPY").Symbol
self.sma = self.SMA(symbol, 20, Resolution.Daily)

history = self.History(symbol, 20, Resolution.Daily)
if not history.empty:
    for time, row in history.loc[symbol].iterrows():
        self.sma.Update(time, row.close)
```

Automatic Indicator Warm-up

You can set the `EnableAutomaticIndicatorWarmUp` property to true before you create indicators to automatically warm them up.

```
# In Initialize
symbol = self.AddEquity("SPY").Symbol
self.EnableAutomaticIndicatorWarmUp = True
self.sma = self.SMA(symbol, 20, Resolution.Daily)
```

Warm-up Helper Method

If an indicator inherits the `IIndicatorWarmUpPeriodProvider` class, you can warm it up with the `WarmUpIndicator` method.

```
self.sma = self.SMA(self.symbol, 20)
self.WarmUpIndicator(self.symbol, self.sma)
```

To warm up the indicator with a resolution that's different from the security resolution, pass a resolution or `timedelta` argument to the `WarmUpIndicator` method. The resolution you provide should be greater than or equal to the security resolution. For example, if the security has minute resolution data, you should warm up the indicator with data that spans at least one minute. If the indicator resolution is different from the security resolution, provide the indicator resolution as the argument to properly warm up the indicator.

```
# Warm up with daily bars
self.WarmUpIndicator(self.symbol, self.sma, Resolution.Daily)

# Warm up with 3-day bars
self.WarmUpIndicator(self.symbol, self.sma, timedelta(days=3))
```

The `WarmUpIndicator` method uses the default `Value` of the historical data to warm up the indicator. In most cases, this is the closing price. To warm up the indicator with a different data field, pass a `Field` argument to the method.

```
self.WarmUpIndicator(self.symbol, self.sma, Resolution.Daily, Field.High)
```

Timing Considerations

In some cases, you might create and warm up the indicator during its sampling period. For example, say the security resolution is minute, the indicator resolution is daily, and you create and warm-up the indicator at noon without using the `SetWarmUp` method. In this example, the history request that gathers data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. It doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Common Mistakes

Avoid the following common mistakes when you use automatic indicators.

Creating Automatic Indicators in a Dynamic Universe

You can't currently remove the consolidator that LEAN creates to update automatic indicators. If you add consolidators to a dynamic universe, the consolidators build up over time and slow down your algorithm. To avoid issues, if you algorithm has a dynamic universe, use manual indicators .

Using Indicator Values Before the Indicator Is Warmed Up

Indicators can provide inaccurate output values before they are warmed up. To avoid issues, always check the `IsReady` flag before you use indicator output values.

```
PY
if self.indicator.IsReady:
    value = self.indicator.Current.Value
```

Manually Registering an Automatic Indicator for Updates

If you create an automatic indicator and then register it for automatics updates or call the `Update` method, the indicator receives multiple input values during each update cycle. To avoid issues, create automatic indicators but don't register them for automatic updates or call the `Update` method.

```
PY
# Create automatic indicators
self.indicator = self.SMA(self.symbol, 5)

# Don't do this:
self.RegisterIndicator(self.symbol, self.indicator, Resolution.Daily)
```

Indicators

Plotting Indicators

Introduction

LEAN provides helper methods to make it simple to create indicator plots.

Plot Update Events

To plot all of the values of some indicators, in the `Initialize` method, call the `PlotIndicator` method. The method plots each indicator value as the indicator updates. The method accepts up to four indicators.

```py
symbol = self.AddEquity("SPY")
sma_short = self.SMA(symbol, 10)
sma_long = self.SMA(symbol, 20)
self.PlotIndicator("<chartName>", sma_short, sma_long)
```

Plot Current Values

To plot the current value of indicators, call the `Plot` method. The method accepts up to four indicators.

```py
# In Initialize
symbol = self.AddEquity("SPY")
sma_short = self.SMA(symbol, 10)
sma_long = self.SMA(symbol, 20)

# In OnData
self.Plot("<chartName>", sma_short, sma_long)
```

View Charts

The following table describes where you can access your charts, depending on how to deploy your algorithms:

Location	Algorithm Lab Algorithms	CLI Cloud Algorithms	CLI Local Algorithms
Backtest results page	✓	✓	
Live results page	✓	✓	
/backtests/read endpoint	✓	✓	
/live/read endpoint	✓	✓	
ReadBacktest method	✓	✓	
ReadLiveAlgorithm method	✓	✓	
Local **JSON** file in your **<projectName> / backtests / <timestamp>** or **<projectName> / live / <timestamp>** directory		✓	✓

Chart Limits

Not all indicators share the same base type(T), so you may not be able to plot them together since some indicators require points while others require `TradeBars` .

```py
# Plot indicators that extend the "Indicator" type
self.PlotIndicators("All Indicator Values", sma, rsi)
self.Plot("Current Indicator Values", sma, rsi);

# Plot indicators that extend the "TradeBarIndicator" type
self.PlotIndicators("All Indicator Values", atr, aroon)
self.Plot("Current Indicator Values", atr, aroon);
```

If your indicator plots are complex, call the `Plot` method with one indicator and plot its `.Current.Value` . For more information about plotting, see Charting .

Indicators

Combining Indicators

Introduction

Indicator extensions let you chain indications together like Lego blocks to create unique combinations. When you chain indicators together, the `.Current.Value` output of one indicator is the input of the following indicator. To chain indicators together with values other than the `.Current.Value` , create a custom indicator .

Addition

The `Plus` extension sums the `.Current.Value` of two indicators or sums the `.Current.Value` of an indicator and a fixed value.

```
# Sum the output of two indicators
rsi_short = self.RSI("SPY", 14)
rsi_long = self.RSI("SPY", 21)
rsi_plus_rsi = IndicatorExtensions.Plus(rsi_short, rsi_long)

# Sum the output of an indicator and a fixed value
rsi_plus_value = IndicatorExtensions.Plus(rsi_short, 10)
```

If you pass an indicator to the `Plus` extension, you can name the composite indicator.

```
named_indicator = IndicatorExtensions.Plus(rsi_short, rsi_long, "RSI Sum")
```

Subtraction

The `Minus` extension subtracts the `.Current.Value` of two indicators or subtracts a fixed value from the `.Current.Value` of an indicator.

```
# Subtract the output of two indicators
sma_short = self.SMA("SPY", 14)
sma_long = self.SMA("SPY", 21)
sma_difference = IndicatorExtensions.Minus(sma_short, sma_long)

# Subtract a fixed value from the output of an indicator
sma_minus_value = IndicatorExtensions.Minus(sma_short, 10)
```

If you pass an indicator to the `Minus` extension, you can name the composite indicator.

```
named_indicator = IndicatorExtensions.Minus(sma_short, sma_long, "SMA Difference")
```

Multiplication

The `Times` extension multiplies the `.Current.Value` of two indicators or multiplies a fixed value and the `.Current.Value` of an indicator.

```py
# Multiply the output of two indicators
ema_short = self.EMA("SPY", 14)
ema_long = self.EMA("SPY", 21)
ema_product = IndicatorExtensions.Times(ema_short, ema_long)

# Multiply the output of an indicator and a fixed value
ema_times_value = IndicatorExtensions.Times(ema_short, 1.5)
```

If you pass an indicator to the `Times` extension, you can name the composite indicator.

```py
named_indicator = IndicatorExtensions.Times(ema_short, ema_long, "EMA Product")
```

Division

The `Over` extension divides the `.Current.Value` of an indicator by the `.Current.Value` of another indicator or a fixed value.

```py
# Divide the output of two indicators
rsi_short = self.RSI("SPY", 14)
rsi_long = self.RSI("SPY", 21)
rsi_division = rsi_short.Over(rsi_long)

# Divide the output of an indicator by a fixed value
rsi_half = IndicatorExtensions.Over(rsi_short, 2)
```

If you pass an indicator to the `Over` extension, you can name the composite indicator.

```py
named_indicator = IndicatorExtensions.Over(rsi_short, rsi_long, "RSI Division")
```

Weighted Average

The `WeightedBy` extension calculates the average `.Current.Value` of an indicator over a lookback period, weighted by another indicator over the same lookback period. The value of the calculation is

$$\frac{\textbf{x} \cdot \textbf{y}}{ \sum\limits_{i=1}^{n} y_{i} }$$

where $\textbf{x}$ is a vector that contains the historical values of the first indicator, $\textbf{y}$ is a vector that contains the historical values of the second indicator, and n is the lookback period.

```py
sma_short = self.SMA("SPY", 14)
sma_long = self.SMA("SPY", 21)
weighted_sma = IndicatorExtensions.WeightedBy(sma_short, sma_long, 3)
```

Custom Chains

The `Of` extension feeds an indicator's `.Current.Value` into the input of another indicator. The first argument of the

`IndicatorExtensions.Of` method must be a manual indicator with no automatic updates. If you pass an indicator that has automatic updates as the argument, that first indicator is updated twice. The first update is from the security data and the second update is from the `IndicatorExtensions` class.

```
rsi = self.RSI("SPY", 14)
rsi_sma = IndicatorExtensions.Of(SimpleMovingAverage(10), rsi) # 10-period SMA of the 14-period RSI
```

If you pass a manual indicator as the second argument, to update the indicator chain, update the second indicator. If you call the `Update` method of the entire indicator chain, it won't update the chain properly.

Simple Moving Average

The `SMA` extension calculates the simple moving average of an indicator's `.Current.Value` .

```
rsi = self.RSI("SPY", 14) # Create a RSI indicator
rsi_sma = IndicatorExtensions.SMA(rsi, 3) # Create an indicator to calculate the 3-period SMA of the RSI
indicator
```

Exponential Moving Average

The `EMA` extension calculates the exponential moving average of an indicator's `.Current.Value` .

```
rsi = self.RSI("SPY", 14) # Create a RSI indicator
rsi_ema = IndicatorExtensions.EMA(rsi, 3) # Create an indicator to calculate the 3-period EMA of the RSI
indicator
```

The `EMA` extension can also accept a smoothing parameter that sets the percentage of data from the previous value that's carried into the next value.

```
rsi_ema = IndicatorExtensions.EMA(rsi, 3, 0.1) # 10% smoothing factor
```

Maximum

The `MAX` extension calculates an indicator's maximum `.Current.Value` over a lookback window.

```
ema = self.EMA("SPY", 14) # Create an EMA indicator
ema_max = IndicatorExtensions.MAX(ema, 10) # Create an indicator to calculate the maximum EMA over the
last 10 periods
```

Minimum

The `MIN` extension calculates an indicator's minimum `.Current.Value` over a lookback window.

```
ema = self.EMA("SPY", 14) # Create an EMA indicator
ema_min = IndicatorExtensions.MIN(ema, 10) # Create an indicator to calculate the minimum EMA over the
last 10 periods
```

Indicators

Custom Indicators

Introduction

LEAN supports over 100 pre-built indicators, but a custom indicator is an indicator you define. It receives input, performs some calculation, and sets its output value. Custom indicators are helpful when you want to achieve any of the following results:

- Use an indicator that LEAN doesn't currently implement
- Combine built-in indicators beyond the logic of Indicator Extensions
- Create your own unique indicator for trading

Define Indicators

Custom indicators must implement the `PythonIndicator` class. The indicator must have an `Update` method and `Name` , `Time` , and `Value` attributes. The `Update` method must accept an `IndicatorDataPoint` , `QuoteBar` , or `TradeBar` and return a boolean that represents if the indicator is ready. The `Time` attribute represents the last time you updated the indicator and the `Value` attribute represents the current indicator value. The following definition provides an example of a custom simple moving average indicator.

```
PY
class CustomSimpleMovingAverage(PythonIndicator):
    def __init__(self, name, period):
        self.Name = name
        self.WarmUpPeriod = period
        self.Time = datetime.min
        self.Value = 0
        self.queue = deque(maxlen=period)

    def Update(self, input: BaseData) -> bool:
        self.queue.appendleft(input.Value)
        count = len(self.queue)
        self.Time = input.Time
        self.Value = sum(self.queue) / count
        return count == self.queue.maxlen
```

Create Indicators

You must define a custom indicator before you can create an instance of it.

To create a custom indicator, call the indicator constructor.

```
PY
self.custom_sma = CustomSimpleMovingAverage("My SMA", 10)
```

Updates

The process to update custom indicators is the same process you use to update manual indicators. For more information about updating manual indicators, see Manual Updates or Automatic Updates .

Warm Up Indicators

The process to warm up custom indicators is the same process you use to warm up manual indicators .

Indicators

Indicator Universes

Introduction

An indicator universe uses technical indicators to determine the constituents of the universe. Imagine a universe that only contains assets above their 10-day simple moving average. You can incorporate indicators into any of the types of universes in the Universes chapter . To create an indicator universe, define a helper class that contains the indicators and then define a universe that updates the indicators and selects assets.

Define SymbolData Objects

To make it easy to create and update indicators for each security in the universe, move the indicator logic into a class. In the universe definition, you can create an instance of this class for each security in the universe.

```
class SymbolData(object):
    def __init__(self, symbol):
        self.symbol = symbol
        self.tolerance = 1.01
        self.fast = ExponentialMovingAverage(100)
        self.slow = ExponentialMovingAverage(300)
        self.is_uptrend = False
        self.scale = 0

    def update(self, time, value):
        if self.fast.Update(time, value) and self.slow.Update(time, value):
            fast = self.fast.Current.Value
            slow = self.slow.Current.Value
            self.is_uptrend = fast > slow * self.tolerance

        if self.is_uptrend:
            self.scale = (fast - slow) / ((fast + slow) / 2.0)
```

PY

Define the Universe

You need to define SymbolData objects before you define the universe that selects securities.

When your universe function receives an object that contains all the possible securities, create a `SymbolData` object for each new security and update the remaining `SymbolData` objects with their daily price or some other data point. For example, the following universe definition selects US Equities that have the greatest difference between two moving averages.

```py
class EmaCrossUniverseSelectionAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        '''Initialise the data and resolution required, as well as the cash and start-end dates for your
algorithm. All algorithms must initialized.'''

        self.SetStartDate(2010,1,1)  #Set Start Date
        self.SetEndDate(2015,1,1)    #Set End Date
        self.SetCash(100000)           #Set Strategy Cash

        self.UniverseSettings.Resolution = Resolution.Daily
        self.UniverseSettings.Leverage = 2

        self.coarse_count = 10
        self.averages = { }

        # this add universe method accepts two parameters:
        # - coarse selection function: accepts an IEnumerable<CoarseFundamental> and returns an
IEnumerable<Symbol>
        self.AddUniverse(self.CoarseSelectionFunction)

    # sort the data by daily dollar volume and take the top 'NumberOfSymbols'
    def CoarseSelectionFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:

        # We are going to use a dictionary to refer the object that will keep the moving averages
        for cf in coarse:
            if cf.Symbol not in self.averages:
                self.averages[cf.Symbol] = SymbolData(cf.Symbol)

            # Updates the SymbolData object with current EOD price
            avg = self.averages[cf.Symbol]
            avg.update(cf.EndTime, cf.AdjustedPrice)

        # Filter the values of the dict: we only want up-trending securities
        values = list(filter(lambda x: x.is_uptrend, self.averages.values()))

        # Sorts the values of the dict: we want those with greater difference between the moving averages
        values.sort(key=lambda x: x.scale, reverse=True)

        for x in values[:self.coarse_count]:
            self.Log('symbol: ' + str(x.symbol.Value) + '  scale: ' + str(x.scale))

        # we need to return only the symbol objects
        return [ x.symbol for x in values[:self.coarse_count] ]
```

Indicators

Rolling Window

Introduction

A `RollingWindow` is an array of a fixed-size that holds trailing data. It's more efficient to use `RollingWindow` objects to hold periods of data than to make multiple historical data requests . With a `RollingWindow` , you just update the latest data point while a `History` call fetches all of the data over the period you request. `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window.

Supported Types

`RollingWindow` objects can store any native or C# types.

```
PY
self.close_window = RollingWindow[float](4)
self.trade_bar_window = RollingWindow[TradeBar](2)
self.quote_bar_window = RollingWindow[QuoteBar](2)
```

To be notified when `RollingWindow` objects support additional types, subscribe to GitHub Issue #6199 .

Add Data

To add data to a `RollingWindow` , call the `Add` method.

```
PY
self.close_window.Add(data["SPY"].Close)
self.trade_bar_window.Add(data["SPY"])
self.quote_bar_window.Add(data["EURUSD"])
```

Warm Up

To warm up a `RollingWindow` , make a history request and then iterate through the result to add the data to the `RollingWindow` .

```
PY
spy = self.AddEquity("SPY", Resolution.Daily).Symbol
history_trade_bar = self.History[TradeBar](spy, 10, Resolution.Daily)
history_quote_bar = self.History[QuoteBar](spy, 10, Resolution.Minute)

# Warm up the close price and trade bar rolling windows with the previous 10-day trade bar data
close_price_window = RollingWindow[float](10)
trade_bar_window = RollingWindow[TradeBar](10)
for trade_bar in history_trade_bar:
    close_price_window.Add(trade_bar.Close)
    trade_bar_window.Add(trade_bar)

# Warm up the quote bar rolling window with the previous 10-minute quote bar data
quote_bar_window = RollingWindow[QuoteBar](10)
for quote_bar in history_quote_bar:
    quote_bar_window.Add(quote_bar)
```

Check Readiness

To check if a `RollingWindow` is full, use its `IsReady` flag.

```
PY
if not self.close_window.IsReady:
    return
```

Access Data

`RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window.

```
PY
current_close = self.close_window[0]
previous_close = self.close_window[1]
oldest_close = self.close_window[self.close_window.Count-1]
```

To get the item that was most recently removed from the `RollingWindow` , use the `MostRecentlyRemoved` property.

```
PY
removed_close = self.close_window.MostRecentlyRemoved
```

Combine with Indicators

To track historical indicator values, use a `RollingWindow` . Indicators emit an `Updated` event when they update. To create a `RollingWindow` of indicator points, attach an event handler function to the `Updated` member that adds the last value of the indicator to the `RollingWindow` . The value is an `IndicatorDataPoint` object that represents a piece of data at a specific time.

```
PY
def Initialize(self) -> None:
    # Creates an indicator and adds to a RollingWindow when it is updated
    self.sma_window = RollingWindow[IndicatorDataPoint](5)
    self.SMA("SPY", 5).Updated += (lambda sender, updated: self.sma_window.Add(updated))
```

To view how to access individual members in an indicator, see Get Indicator Values .

```
PY
current_sma = self.sma_window[0]
previous_sma = self.sma_window[1]
oldest_sma = self.sma_window[sma_window.Count - 1]
```

Combine with Consolidators

To store a history of consolidated bars , in the consolidation handler, add the consolidated bar to the `RollingWindow` .

```
PY
self.consolidator.DataConsolidated += lambda sender, consolidated_bar:
self.trade_bar_window.Add(consolidated_bar)
```

Cast to Other Types

You can cast a `RollingWindow` to a list or a DataFrame. If you cast it to a list, reverse the list so the most recent element is at the last index of the list. This is the order the elements would be in if you added the elements to the list with the `Add` method. To cast a `RollingWindow` to a DataFrame, the `RollingWindow` must contain `Slice` , `Tick` , `QuoteBar` , or `TradeBar` objects. If the `RollingWindow` contains ticks, the ticks must have unique timestamps.

```
PY

closes = list(self.close_window)[::-1]

tick_df = self.PandasConverter.GetDataFrame[Tick](list(self.tick_window)[::-1])
trade_bar_df = self.PandasConverter.GetDataFrame[TradeBar](list(self.trade_bar_window)[::-1])
quote_bar_df = self.PandasConverter.GetDataFrame[QuoteBar](list(self.quote_bar_window)[::-1])
```

Delete Data

To remove all of the elements from a `RollingWindow` , call the `Reset` method.

```
PY

self.close_window.Reset()
```

Examples

Demonstration Algorithm
RollingWindowAlgorithm.py Python CustomVolatilityModelAlgorithm.py Python
MultipleSymbolConsolidationAlgorithm.py Python

Object Store

Introduction

The Object Store is a file system that you can use in your algorithms to save, read, and delete data. The Object Store is organization-specific, so you can save or read data from the same Object Store in all of your organization's projects. The Object Store works like a key-value storage system where you can store regular strings, JSON encoded strings, XML encoded strings, and bytes. You can access the data you store in the Object Store from backtests, the Research Environment, and live algorithms.

Get All Stored Data

To get all of the keys and values in the Object Store, iterate through the `ObjectStore` object.

```
PY
for kvp in self.ObjectStore:
    key = kvp.Key
    value = kvp.Value
```

To iterate through just the keys in the Object Store, iterate through the `Keys` property.

```
PY
for key in self.ObjectStore.Keys:
    continue
```

Create Sample Data

You need some data to store data in the Object Store.

Follow these steps to create some sample data:

1. Create a `string` .

   ```
   PY
   string_sample = "My string"
   ```

2. Create a `Bytes` object.

   ```
   PY
   bytes_sample = str.encode("My String")
   ```

Save Data

The Object Store saves objects under a key-value system. If you save objects in backtests, you can access them from the Research Environment. To avoid slowing down your backtests, save data once in the `OnEndOfAlgorithm` event handler. In live trading, you can save data more frequently like at the end of a `Train` method or after universe selection.

If you run algorithms in QuantConnect Cloud, you need storage create permissions to save data in the Object Store.

If you don't have data to store, create some sample data .

You can save `Bytes` and `string` objects in the Object Store. To store data, you need to provide a key. If you provide a key that is already in the Object Store, it will overwrite the data at that location. To avoid overwriting objects from other projects in your organization, prefix the key with your project ID. You can find the project ID in the URL of your browser when you open a project. For example, the ID of the project at **quantconnect.com/project/12345** is 12345.

Bytes

To save a `Bytes` object, call the `SaveBytes` method.

```
save_successful = self.ObjectStore.SaveBytes(f"{self.ProjectId}/bytes_key", bytes_sample)
```

Strings

To save a `string` object, call the `Save` or `SaveString` method.

```
save_successful = self.ObjectStore.Save(f"{self.ProjectId}/string_key", string_sample)
```

Read Data

Read data from the Object Store to import algorithm variables between deployments, import data from the Research Environment, or load trained machine learning models. To read data from the Object Store, you need to provide the key you used to store the object.

You can load `Bytes` and `string` objects from the Object Store.

Before you read data from the Object Store, check if the key exists.

```
if self.ObjectStore.ContainsKey(key):
    # Read data
```

Bytes

To read a `Bytes` object, call the `ReadBytes` method.

```
byte_data = self.ObjectStore.ReadBytes(f"{self.ProjectId}/bytes_key")
```

Strings

To read a `string` object, call the `Read` or `ReadString` method.

```
string_data = self.ObjectStore.Read(f"{self.ProjectId}/string_key")
```

Delete Data

Delete objects in the Object Store to remove objects that you no longer need. If you run algorithms in QuantConnect Cloud, you need storage delete permissions to delete data from the Object Store.

To delete objects from the Object Store, call the `Delete` method. Before you delete data, check if the key exists. If you try to delete an object with a key that doesn't exist in the Object Store, the method raises an exception.

```
PY
if self.ObjectStore.ContainsKey(key):
    self.ObjectStore.Delete(key)
```

To delete all of the content in the Object Store, iterate through all the stored data.

```
PY
for kvp in self.ObjectStore:
    self.ObjectStore.Delete(kvp.Key)
```

Cache Data

When you write to or read from the Object Store, the algorithm caches the data. The cache speeds up the algorithm execution because if you try to read the Object Store data again with the same key, it returns the cached data instead of downloading the data again. The cache speeds up execution, but it can cause problems if you are trying to share data between two nodes under the same Object Store key. For example, consider the following scenario:

1. You open project A and save data under the key `123` .
2. You open project B and save new data under the same key `123` .
3. In project A, you read the Object Store data under the key `123` , expecting the data from project B, but you get the original data you saved in step #1 instead.

   You get the data from step 1 instead of step 2 because the cache contains the data from step 1.

To clear the cache, call the `Clear` method.

```
PY
self.ObjectStore.Clear()
```

Get File Path

To get the file path for a specific key in the Object Store, call the `GetFilePath` method. If the key you pass to the method doesn't already exist in the Object Store, it's added to the Object Store.

```
PY
file_path = self.ObjectStore.GetFilePath(key)
```

Storage Quotas

If you run algorithms locally, you can store as much data as your hardware will allow. If you run algorithms in QuantConnect Cloud, you must stay within your storage quota . If you need more storage space, edit your storage plan

.

Example for Plotting

You can use the `ObjectStore` to plot data from your backtests and live algorithm in the Research Environment. In the following example, you will learn how to plot the Simple Moving Average indicator generated in a backtest.

1. Create a algorithm, add a data subscription and a Simple Moving Average indicator.

```
class ObjectStoreChartingAlgorithm(QCAlgorithm):
    def Initialize(self):
        self.AddEquity("SPY")

        self.content = ''
        self.sma = self.SMA("SPY", 22)
```

   The algorithm will save `self.content` to the `ObjectStore` .

2. Save indicator data as `string` in `self.content` .

```
def OnData(self, data: Slice):
    self.Plot('SMA', 'Value', self.sma.Current.Value)
    self.content += f'{self.sma.Current.EndTime},{self.sma.Current.Value}\n'
```

3. To store the collected data, call the `Save` method with a key.

```
def OnEndOfAlgorithm(self):
    self.ObjectStore.Save('sma_values_python', self.content)
```

4. Open the Research Environment, and create a `QuantBook` .

```
qb = QuantBook()
```

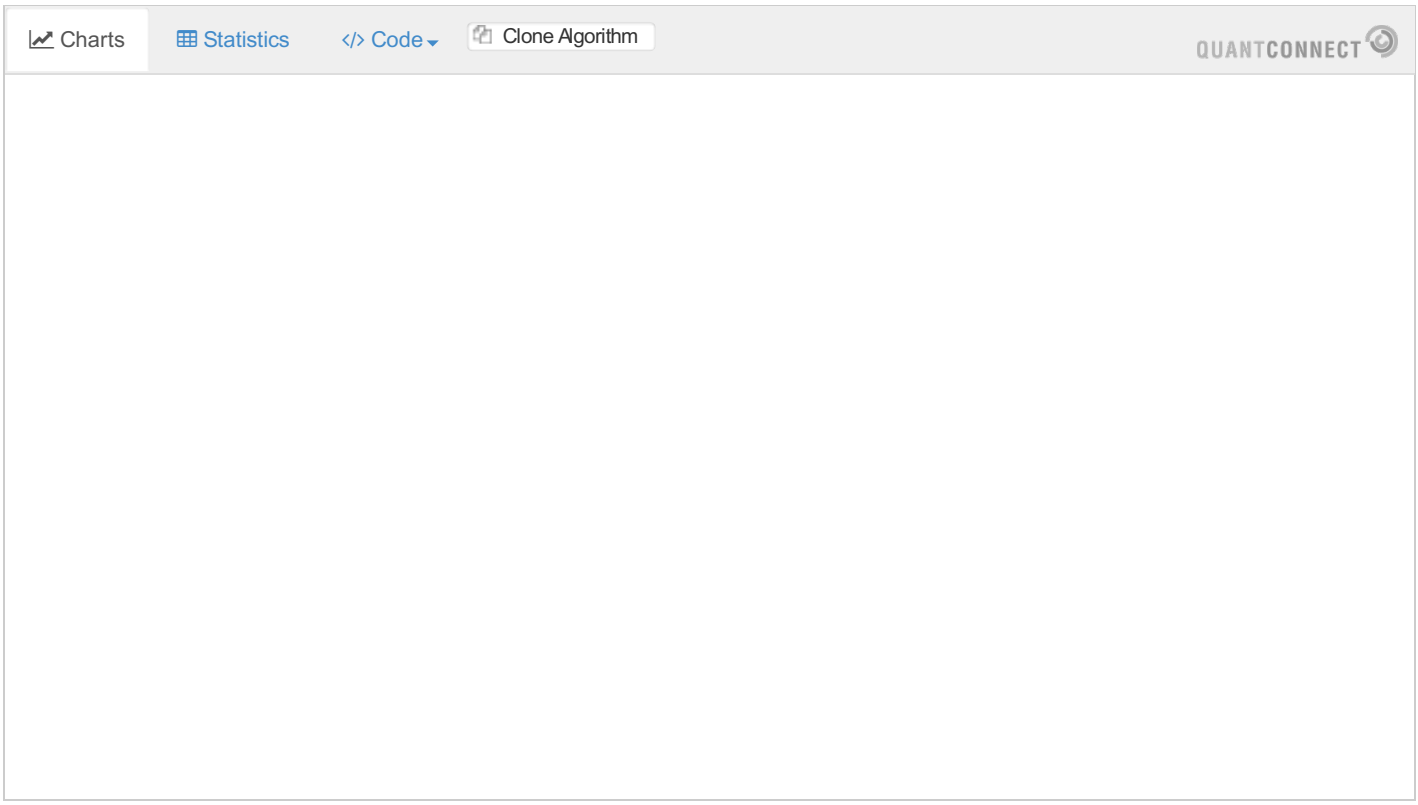
5. To read data from the Object Store, call the `Read` method. You need to provide the key you used to store the object.

```
content = qb.ObjectStore.Read("sma_values_python")
```

6. Convert the data to a pandas object, and create a chart.

```
data = {}
for line in content.split('\n'):
    csv = line.split(',')
    if len(csv) > 1:
        data[csv[0]] = float(csv[1])

series = pd.Series(data, index=data.keys())
series.plot()
```



Preserve Insights Between Deployments

Follow these steps to use the Object Store to preserve the algorithm state across live deployments:

1. Create an algorithm that defines a storage key and adds insights to the Insight Manager .

```
class ObjectStoreChartingAlgorithm(QCAlgorithm):
    def Initialize(self):
        self.insight_key = f"{self.ProjectId}/insights"
        self.SetUniverseSelection(ManualUniverseSelectionModel([ Symbol.Create("SPY",
SecurityType.Equity, Market.USA) ]))
        self.SetAlpha(ConstantAlphaModel(InsightType.Price, InsightDirection.Up, timedelta(5), 0.025,
None))
```

2. At the top of the algorithm file, add the following imports:

```
from Newtonsoft.Json import JsonConvert
from System.Collections.Generic import List
```

   `Insight` objects are a C# objects, so you need the preceding C# libraries to serialize and deserialize them.

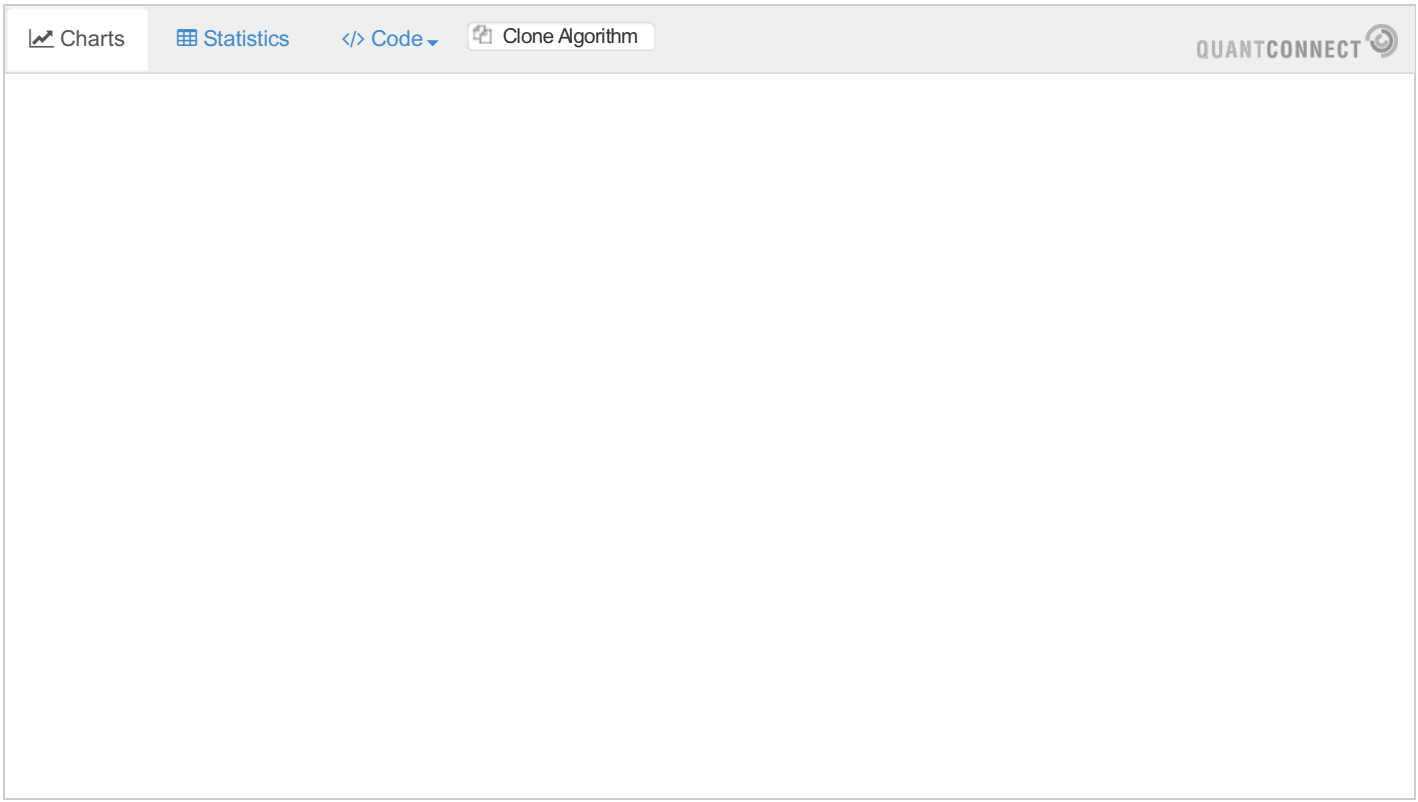
3. In the OnEndOfAlgorithm event handler of the algorithm, get the Insight objects and save them in the Object Store as a JSON object.

```
def OnEndOfAlgorithm(self):
    insights = self.Insights.GetInsights(lambda x: x.IsActive(self.UtcTime))
    content = ','.join([JsonConvert.SerializeObject(x) for x in insights])
    self.ObjectStore.Save(self.insight_key, f'[{content}]')
```

4. At the bottom of the `Initialize` method, read the Insight objects from the Object Store and add them to the Insight Manager .

```
if self.ObjectStore.ContainsKey(self.insight_key):
    insights = self.ObjectStore.ReadJson[List[Insight]](self.insight_key)
    self.Insights.AddRange(insights)
```

The following algorithm provides a full example of preserving the Insight state between deployments:



Live Trading Considerations

If you update the Object Store from outside of your live trading node and then try to read the new content from inside your live trading algorithm, you may not get the new content because the Object Store caches data to speed up execution. To ensure you get the latest value for a specific key in the Object Store, clear the cache and then read the data .

```
self.ObjectStore.Clear()
if self.ObjectStore.ContainsKey(key):
    value = self.ObjectStore.Read(key)
```

Parameters

Introduction

Parameters are project variables that your algorithm uses to define the value of internal variables like indicator arguments or the length of lookback windows. Parameters are stored outside of your algorithm code, but we inject the values of the parameters into your algorithm when you run a backtest, deploy a live algorithm, or launch an optimization job. To use parameters, set some parameters in your project and then load them into your algorithm.

Set Parameters

The process to set parameter values depends on the environment you use to write algorithms. See the tutorial in one of the following environments:

- Cloud Platform
- Local Platform
- LEAN CLI

Get Parameters

To get a parameter value into your algorithm, call the `GetParameter` method of the algorithm class.

```py
parameter_value = self.GetParameter("parameterName")
```

The `GetParameter` method returns a string by default. If you provide a default parameter value, the method returns the parameter value as the same data type as the default value. If there are no parameters in your project that match the name you pass to the method and you provide a default value to the method, it returns the default value. The following table describes the arguments the `GetParameter` method accepts:

Argument	Data Type	Description	Default Value
`name`	`str`	The name of the parameter to get	
`defaultValue`	`str/int/double`	The default value to return	`None`

The following example algorithm gets the values of parameters of each data type:

```py
class ParameterizedAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        # Get the parameter value and return an integer
        int_parameter_value = self.GetParameter("<int_parameter_name>", 100)

        # Get the parameter value and return a double
        float_parameter_value = self.GetParameter("<float_parameter_name>", 0.95)

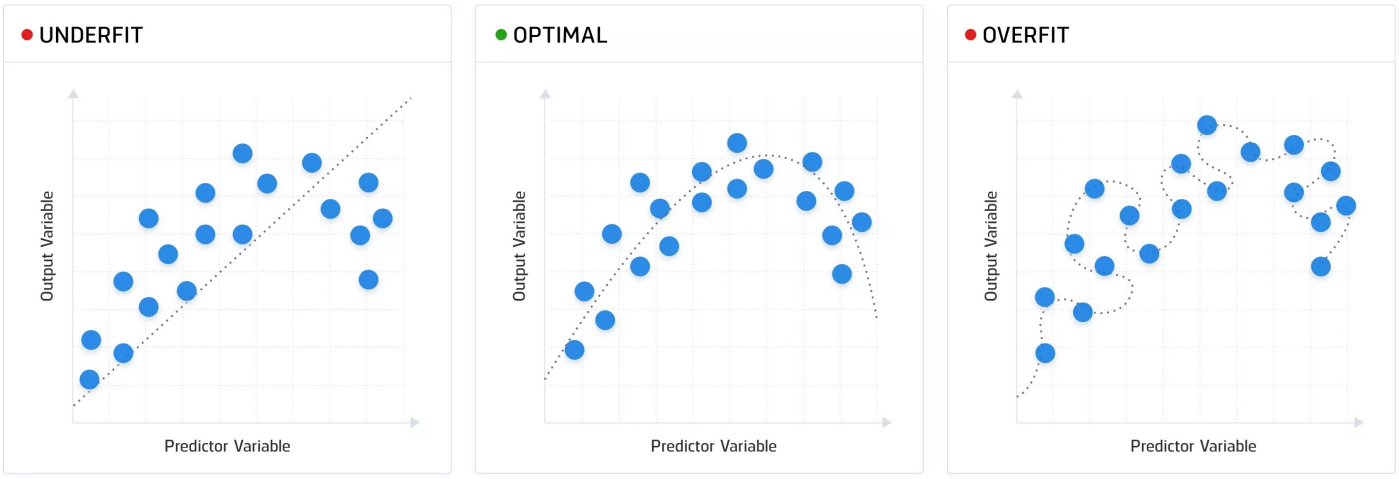
        # Get the parameter value as a string
        string_parameter_value = self.GetParameter("<parameter_name>", "default_string_value")

        # Cast it to an integer
        parameter_value = int(string_parameter_value)
```

The parameter values are sent to your algorithm when you deploy the algorithm, so it's not possible to change the parameter values while the algorithm runs.

Overfitting

Overfitting occurs when a function is fit too closely fit to a limited set of training data. Overfitting can occur in your trading algorithms if you have many parameters or select parameters values that worked very well in the past but are sensitive to small changes in their values. In these cases, your algorithm will likely be fine-tuned to fit the detail and noise of the historical data to the extent that it negatively impacts the live performance of your algorithm. The following image shows examples of underfit, optimally-fit, and overfit functions:



An algorithm that is dynamic and generalizes to new data is more likely to survive across different market conditions and apply to other markets.

Look-Ahead Bias

Look-ahead bias occurs when an algorithm makes decisions using data that would not have yet been available. For instance, in optimization jobs, you optimize a set of parameters over a historical backtesting period. After the optimizer finds the optimal parameter values, the backtest period becomes part of the in-sample data. If you run a backtest over the same period using the optimal parameters, look-ahead bias has seeped into your research. In reality, it would not be possible to know the optimal parameters during the testing period until after the testing period is over. To avoid issues with look-ahead bias, optimize on older historical data and test the optimal parameter values on recent historical data. Alternatively, apply walk forward optimization to optimize the parameters on smaller batches of history.

Live Trading Considerations

To update parameters in live mode, add a Schedule Event that downloads a remote file and uses its contents to update the parameter values.

```py
def Initialize(self):
    self.parameters = { }
    if self.LiveMode:
        def download_parameters():
            content = self.Download(url_to_remote_file)
            # Convert content to self.parameters

        self.Schedule.On(self.DateRules.EveryDay(), self.TimeRules.Every(timedelta(minutes=1)),
download_parameters)
```

Examples

The following example algorithm demonstrates loading parameter values :

```py
class ParameterizedAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2020, 1, 1)
        self.SetCash(100000)
        self.AddEquity("SPY")

        fast_period = self.GetParameter("ema-fast", 100)
        slow_period = self.GetParameter("ema-slow", 200)

        self._fast = self.EMA("SPY", fast_period)
        self._slow = self.EMA("SPY", slow_period)
```

Machine Learning

Machine Learning

Key Concepts

Introduction

Machine learning is a field of study that combines statistics and computer science to build intelligent systems that predict outcomes. You can use machine learning techniques in your trading strategies.

Supported Libraries

LEAN supports several machine learning libraries. You can import these packages and use them in your algorithms.

Name	Version	Language	Import Statement	Exam
TensorFlow	2.11.0	Python	`import tensorflow`	
SciKit Learn	1.2.1	Python	`import sklearn`	
Py Torch	1.13.1	Python	`import torch`	
Keras	2.11.0	Python	`import keras`	
gplearn	0.4.2	Python	`import gplearn`	
hmmlearn	0.2.8	Python	`import hmmlearn`	
tsfresh	0.20.0	Python	`import tsfresh`	
Stable-Baselines3	1.7.0	Python	`from stable_baselines3 import *`	
fastai	2.7.11	Python	`import fastai`	
Deap	1.3.3	Python	`import deap`	
XGBoost	1.7.4	Python	`import xgboost`	
mlfinlab	1.6.0	Python	`import mlfinlab`	
Accord	3.6.0	C#	`using Accord.MachineLearning;`	

Add New Libraries

To request a new library, contact us . We will add the library to the queue for review and deployment. Since the libraries

run on our servers, we need to ensure they are secure and won't cause harm. The process of adding new libraries takes 2-4 weeks to complete. View the list of libraries currently under review on the Issues list of the Lean GitHub repository .

Save Models

After you train a model, you can save it into the Object Store . In QuantConnect Cloud, we back up your Object Store data on QuantConnect servers. In local algorithms, your local machine saves the Object Store data. If you save models in live algorithms, save them at the end of the training method so you can access the trained model again if your algorithm stops executing. If you save models in backtests, save them during the `OnEndOfAlgorithm` event handler so that saving multiple times doesn't slow down your backtest.

To view examples of storing library-specific models, see Popular Libraries .

Load Models

You can load machine learning models from the Object Store or a custom data file like pickle. If you load models from the Object Store, before you load the model into your algorithm, in the `Initialize` method, check if the Object Store already contains the model. To avoid look-ahead bias in backtests, don't train your model on the same data you use to test the model.

Machine Learning

Training Models

Introduction

Algorithms usually must process each timeslice within 10 minutes, but the `Train` method allows you to increase this time to train machine learning models. The length of time you can train depends on your training quotas.

Train Models

To train models immediately, call the `Train` method and pass in the name of your training method.

```
self.Train(self.MyMethod)
```

Immediate training is most useful for training your model when you first deploy your strategy to production or when the model's performance begins to degrade.

Schedule Training Sessions

You can schedule model training sessions in a similar way to a Scheduled Event. To schedule a training session do this, pass in a DateRules and TimeRules argument to the `Train` method.

```
# Set TrainingMethod to be executed at 8:00 am every Sunday
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8,0), self.MyTrainingMethod)
```

We recommend you schedule your training sessions for when the market is closed to get the best compute allocation. While the market is open, your CPU is occupied with processing incoming tick data and handling other LEAN events.

Training Quotas

Training resources are allocated with a leaky bucket algorithm where you can use a maximum of n-minutes in a single training session and the number of available minutes refills over time. This design gives you burst allocations when you need them and recharges the allowance to prepare for the next training.

Cloud Quotas

If you execute algorithms in QuantConnect Cloud, see Training Quotas for more information about the training quotas.

Local Quotas

If you execute algorithms locally, the following table shows the default settings for the leaky bucket algorithm:

Setting	Value
Capacity (minutes)	120
Time interval (minutes)	1440
Refill amount (minutes per time interval)	Capacity / 7

To allow virtually unlimited training for local algorithms, add the following key-value pairs to your **Lean / Launcher / config.json** file:

```
"scheduled-event-leaky-bucket-capacity" : 99999999,
"scheduled-event-leaky-bucket-time-interval-minutes" : 1,
"scheduled-event-leaky-bucket-refill-amount": 999999,
```

Check Model Readiness

In backtests, the `Train` method is synchronous, so it blocks your algorithm execution while the model trains. In live trading, the `Train` method is asynchronous, so ensure your model is trained before you continue the algorithm execution. Training occurs on a separate thread, so set a boolean flag to notify your algorithm of the model state. A **semaphore** is a thread-safe flag you can use to synchronize program operations across different threads.

PY

```
class SemaphoreTrainingAlgorithm(QCAlgorithm):

    # Model Object
    model = None
    # Model State Flag
    model_is_training = False

    def Initialize(self) -> None:
        self.Train(self.my_training_method)

    def my_training_method(self) -> None:
        self.model_is_training = True
        # Perform Work
        self.model_is_training = False

    def OnData(self, slice: Slice) -> None:
        # Do not use model while it is being trained.
        if self.model_is_training:
            return

        # Once training is complete; use the model safely.
        result = self.model.Predict()
```

Popular Libraries

GPlearn

Introduction

This page explains how to build, train, deploy and store `GPlearn` models.

Import Libraries

Import the `gplearn` and `joblib` libraries.

```
PY
from AlgorithmImports import *
from gplearn.genetic import SymbolicRegressor, SymbolicTransformer
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `GPLearn` model and make predictions.

```
PY
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

Build Models

In this example, build a genetic programming feature transformation model and a genetic programming regression prediction model using the following features and labels:

Data Category	Description
Features	Daily percent change of the close price of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow these steps to create a method to build the model:

1. Declare a set of functions to use for feature engineering.

```
function_set = ['add', 'sub', 'mul', 'div',
                'sqrt', 'log', 'abs', 'neg', 'inv',
                'max', 'min']
```

2. Call the `SymbolicTransformer` constructor with the preceding set of functions and then save it as a class variable.

```
self.gp_transformer = SymbolicTransformer(function_set=function_set)
```

3. Call the `SymbolicRegressor` constructor to instantiate the regression model.

```
self.model = SymbolicRegressor()
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
training_length = 252*2
self.training_data = RollingWindow[float](training_length)
history = self.History[TradeBar](self.symbol, training_length, Resolution.Daily)
for trade_bar in history:
    self.training_data.Add(trade_bar.Close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
PY
def get_features_and_labels(self, n_steps=5):
    training_df = list(self.training_data)[::-1]
    daily_pct_change = ((np.roll(training_df, -1) - training_df) / training_df)[:-1]

    features = []
    labels = []
    for i in range(len(daily_pct_change)-n_steps):
        features.append(daily_pct_change[i:i+n_steps])
        labels.append(daily_pct_change[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()

    # Feature engineering
    self.gp_transformer.fit(features, labels)
    gp_features = self.gp_transformer.transform(features)
    new_features = np.hstack((features, gp_features))

    # Fit the regression model with transformed and raw features.
    self.model.fit(new_features, labels)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
PY
self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
PY
# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current close price to the `RollingWindow` that holds the training data.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol].Close)
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

```
features, _ = self.get_features_and_labels()

# Get transformed features
gp_features = self.gp_transformer.transform(features)
new_features = np.hstack((features, gp_features))

# Get next prediction
prediction = self.model.predict(new_features)
prediction = float(prediction.flatten()[-1])
```

You can use the label prediction to place orders.

```
if prediction > 0:
    self.SetHoldings(self.symbol, 1)
elif prediction < 0:
    self.SetHoldings(self.symbol, -1)
```

Save Models

Follow these steps to save `GPLearn` models into the ObjectStore :

1. Set the key names you want to store the models under in the ObjectStore.

   ```
   transformer_model_key = "transformer"
   regressor_model_key = "regressor"
   ```

2. Call the `GetFilePath` method with the keys.

   ```
   transformer_file_name = self.ObjectStore.GetFilePath(transformer_model_key)
   regressor_file_name = self.ObjectStore.GetFilePath(regressor_model_key)
   ```

   This method returns the file paths where the models will be stored.

3. Call the `dump` method the file paths.

   ```
   joblib.dump(self.gp_transformer, transformer_file_name)
   joblib.dump(self.model, regressor_file_name)
   ```

   If you dump the models using the `joblib` module before you save the models, you don't need to retrain the models.

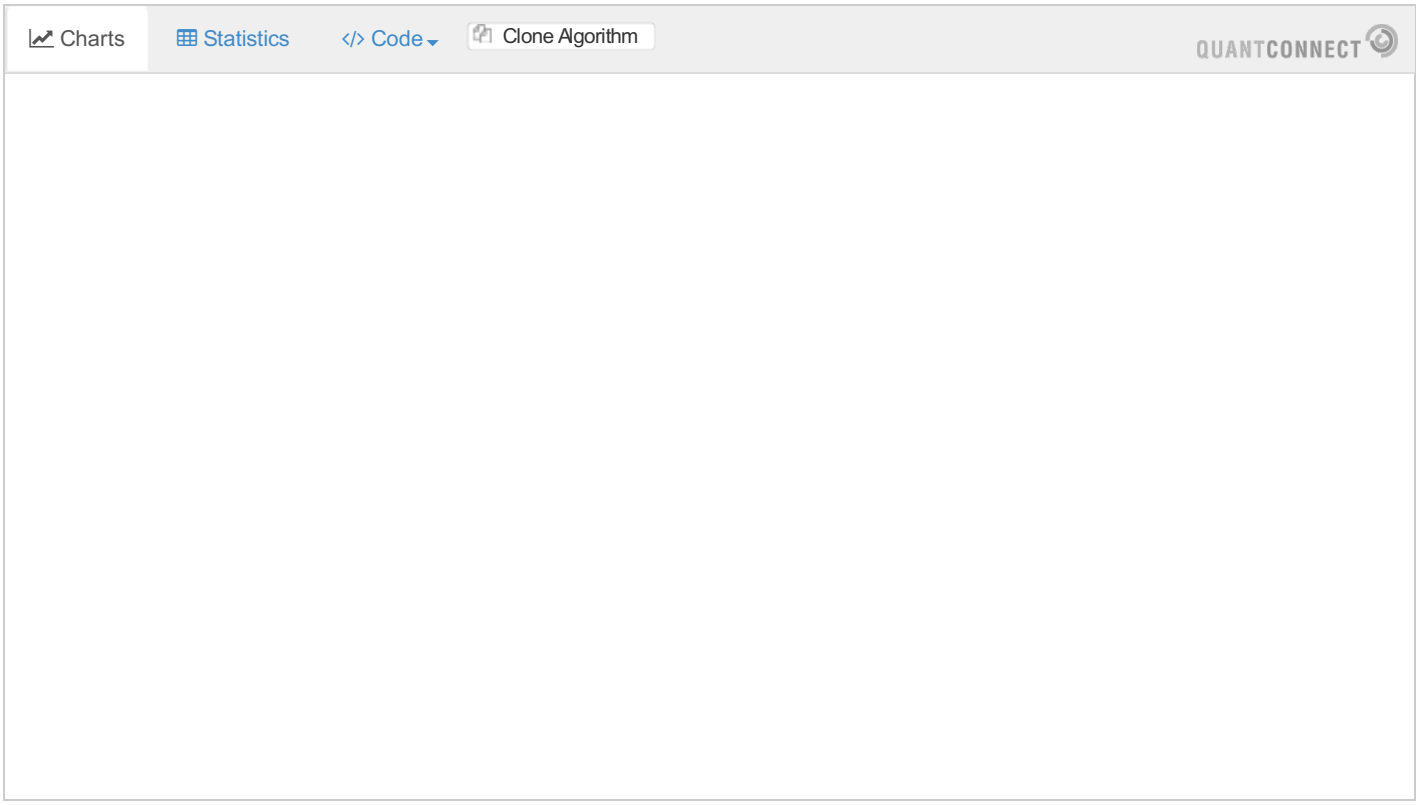
Load Models

You can load and trade with pre-trained `GPLearn` models that you saved in the ObjectStore. To load a `GPLearn` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

```
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(transformer_model_key) and
self.ObjectStore.ContainsKey(regressor_model_key):
        transformer_file_name = self.ObjectStore.GetFilePath(transformer_model_key)
        regressor_file_name = self.ObjectStore.GetFilePath(regressor_model_key)
        self.gp_transformer = joblib.load(transformer_file_name)
        self.model = joblib.load(regressor_file_name)
```
PY

The `ContainsKey` method returns a boolean that represents if `transformer_model_key` and `regressor_model_key` are in the ObjectStore. If the ObjectStore does not contain the keys, save the model using them before you proceed.

Clone Example Algorithm



Popular Libraries

Hmmlearn

Introduction

This page explains how to build, train, deploy and store `Hmmlearn` models.

Import Libraries

Import the `hmmlearn` and `joblib` libraries.

```
PY
from AlgorithmImports import *
from hmmlearn import hmm
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `hmmlearn` model and make predictions.

```
PY
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

Build Models

In this example, assume the market has only 2 regimes and the market returns follow a Gaussian distribution. Therefore, create a 2-component Hidden Markov Model with Gaussian emissions, which is equivalent to a Gaussian mixture model with 2 means.

To build the model, call the `GaussianHMM` constructor with the number of components, a covariance type, and the number of iterations:

```
PY
self.model = hmm.GaussianHMM(n_components=2, covariance_type="full", n_iter=100)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
training_length = 252*2
self.training_data = RollingWindow[float](training_length)
history = self.History[TradeBar](self.symbol, training_length, Resolution.Daily)
for trade_bar in history:
    self.training_data.Add(trade_bar.Close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
def get_features(self):
    training_df = np.array(list(self.training_data)[::-1])
    daily_pct_change = (np.roll(training_df, 1) - training_df) / training_df

    return daily_pct_change[1:].reshape(-1, 1)

def my_training_method(self):
    features = self.get_features()
    self.model.fit(features)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current close price to the `RollingWindow` that holds the training data.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol].Close)
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

```
new_feature = self.get_features()
prediction = self.model.predict(new_feature)
prediction = float(prediction[-1])
```

You can use the label prediction to place orders.

```
if prediction == 1:
    self.SetHoldings(self.symbol, 1)
else:
    self.Liquidate(self.symbol)
```

Save Models

Follow these steps to save `hmmlearn` models into the ObjectStore :

1. Set the key name you want to store the model under in the ObjectStore.

   ```
   model_key = "model.hmm"
   ```

2. Call the `GetFilePath` method with the key.

   ```
   file_name = self.ObjectStore.GetFilePath(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   ```
   joblib.dump(self.model, file_name)
   ```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

You can load and trade with pre-trained `hmmlearn` models that you saved in the ObjectStore. To load a `hmmlearn` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

```
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(model_key):
        file_name = self.ObjectStore.GetFilePath(model_key)
        self.model = joblib.load(file_name)
```

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the ObjectStore. If the ObjectStore does not contain the `model_key` , save the model using the `model_key` before you proceed.

Code
Clone Algorithm
QUANTCONNECT

Popular Libraries

Keras

Introduction

This page explains how to build, train, deploy and store `Keras` models.

Import Libraries

Import the `keras` libraries.

```
PY
from AlgorithmImports import *
from tensorflow.keras.models import Sequential, load_model
from tensorflow.keras.layers import Dense, Flatten
from tensorflow.keras.optimizers import Adam
```

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `keras` model and make predictions.

```
PY
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

Build Models

In this example, build a neural-network regression model that uses the following features and labels:

Data Category	Description
Features	Daily percent change of the open, high, low, close, and volume of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow the below steps to build the model:

1. In the `Initialize` method, create a `Sequential` object with several layers.

```
PY
self.model = Sequential([Dense(10, input_shape=(5,5), activation='relu'),
                         Dense(10, activation='relu'),
                         Flatten(),
                         Dense(1)])
```

   Set the `input_shape` of the first layer to `(5, 5)` because each sample contains the percent change of 5 factors (percent change of the open, high, low, close, and volume) over the previous 5 days. Call the `Flatten` constructor because the input is 2-dimensional but the output is just a single value.

2. Call the `compile` method with a loss function, an optimizer, and a list of metrics to monitor.

```
PY
self.model.compile(loss='mse',
                   optimizer=Adam(),
                   metrics=['mae', 'mse'])
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
training_length = 252*2
self.training_data = RollingWindow[TradeBar](training_length)
history = self.History[TradeBar](self.symbol, training_length, Resolution.Daily)
for trade_bar in history:
    self.training_data.Add(trade_bar)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
def get_features_and_labels(self, n_steps=5):
    training_df = self.PandasConverter.GetDataFrame[TradeBar](list(self.training_data)[::-1])
    daily_pct_change = training_df.pct_change().dropna()

    features = []
    labels = []
    for i in range(len(daily_pct_change)-n_steps):
        features.append(daily_pct_change.iloc[i:i+n_steps].values)
        labels.append(daily_pct_change['close'].iloc[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()
    self.model.fit(features, labels, epochs=5)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol])
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict`

method.

```
features, _ = self.get_features_and_labels()
features = features[-1].reshape(1, 5, 5)
prediction = float(self.model.predict(features)[-1])
```

You can use the label prediction to place orders.

```
if prediction > 0:
    self.SetHoldings(self.symbol, 1)
elif prediction < 0:
    self.SetHoldings(self.symbol, -1)
```

Save Models

Follow these steps to save `keras` models into the ObjectStore :

1. Set the key name you want to store the model under in the ObjectStore.

   ```
   model_key = "model"
   ```

2. Call the `GetFilePath` method with the key.

   ```
   file_name = self.ObjectStore.GetFilePath(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `save` method with the file path.

   ```
   self.model.save(file_name)
   ```

Load Models

You can load and trade with pre-trained `keras` models that you saved in the ObjectStore. To load a `keras` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `load_model` method.

```
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(model_key):
        file_name = self.ObjectStore.GetFilePath(model_key)
        self.model = load_model(file_name)
```

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the ObjectStore. If the ObjectStore does not contain the `model_key` , save the model using the `model_key` before you proceed.

MlFinLab

Introduction

MlFinLab is a collection of production-ready algorithms (from the best journals and graduate-level textbooks), packed into a python library that enables portfolio managers and traders who want to leverage the power of machine learning by providing reproducible, interpretable, and easy to use tools. It covers every step of the machine learning strategy creation starting from data structures generation and finishing with backtest statistics.

The mission of Hudson and Thames is to promote the scientific method within investment management by codifying frameworks, algorithms, and best practices to build the world's central repository of ready to use implementations and intellectual property. For more information, see the Hudson and Thames website . The Hudson and Thames environment, which includes the MlFinLab library, is currently only available in QuantConnect Cloud.

Import Libraries

Follow these steps to import the `mlfinlab` library:

1. Open a project .
2. In the Project panel, click the **LEAN Environment** field and then click **Hudson & Thames** from the drop-down menu.
3. Open one of the code files in your project.
4. At the top of the code file, add the following snippet:

```
PY
import ht_auth
ht_auth.SetToken("<mlfinlab_api_key>")
import mlfinlab as ml
```

MlFinLab costs £100 (+VAT) per month, per user. Follow these steps to get your API key:

1. Create a profile on the Hudson & Thames website and log in.
2. On the dashboard page under MlFinLab, click **Buy** .
3. On the MlFinLab page, click **Buy** .
4. In the Terms of Use window, accept the terms of use and then click **Purchase** .
5. In the Purchase MlFinLab window, enter your payment card details and then click **Subscribe Now** .
6. Wait for the success window to display.
7. On the dashboard page, under MlFinLab, click **View** .
8. On the MlFinLab page, click **Copy API Key** .

Financial Data Structures

Transform unstructured data sets into structured tick, volume, and dollar bars as well as the less common information-

driven bars. With MlFinLab you can even generate bars on the go with our online data structures framework. For more information about data structures, see Standard Bars in the MlFinLab documentation.

Labeling Techniques

MlFinLab provides a comprehensive list of labeling techniques, including the following: Raw Returns, Fixed Horizon, Triple-Barrier & Meta-Labeling, and many more. For more information about labeling, see Labeling in the MlFinLab documentation.

Feature Engineering

This section of MlFinLab contains several important tools to manipulate, select and transform raw data into useful features. Feature engineering techniques you can use include: Fractionally Differentiated Features, Structural Breaks, Volatility Estimators, and even Automatic Feature Extraction. For more information about feature engineering, see Feature Importance in the MlFinLab documentation.

Bet Sizing

This section will allow you to optimally size your bets to improve returns or limit downside metrics in alignment with your risk preferences. Methods include Kelly Criterion, EF3M and dynamic bet sizes. For more information about bet sizing, see Bet Sizing in the MlFinLab documentation.

Codependence Measures

Improve your strategies by taking into account measures of codependence between assets in MlFinLab. Choose between correlation-based, information theory and copula-based metrics. For more information about codependence measures, see Measures of Codependence in the MlFinLab documentation.

Generate Sythetic Data

Generate data that simulate important events for example, flash crashes, world-wide economic crises, global pandemics, etc. to assess if an algorithm will fare well for any event. Having an abundance of realistic financial data has never been easier with MlFinLab. Examples of financial data that can be generated include stock prices, stock returns, correlation matrices, retail banking data, and all kinds of market microstructure data. For more information about synthetic data, see Synthetic Data Generation in the MlFinLab documentation.

Clustering Techniques

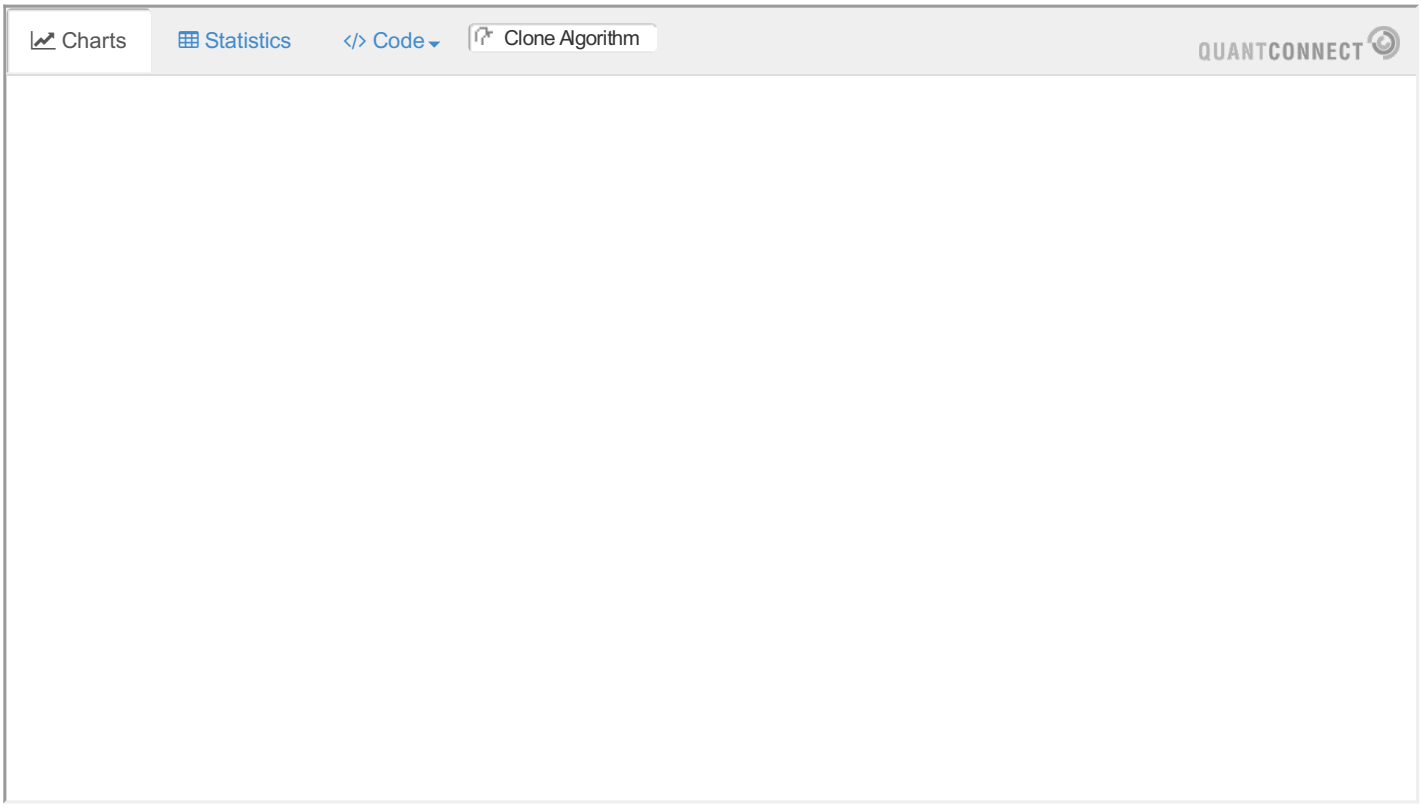
Discover a wide range of clustering techniques at your fingertips to improve the credibility of your investment strategy. MlFinLab offers both hierarchical clustering techniques and the ability to determine the optimal number of clusters. For more information about clustering techniques, see Clustering in the MlFinLab documentation.

Networks Modeling

Creates beautiful and informative visualizations of financial data, using network theory to describe complex systems such as financial markets. Use graphs such as a Minimum Spanning Tree, creating a mini Flask server using Plotly's Dash to display the interactive graphs with MlFinLab. For more information about networks modeling, see Networks in the MlFinLab documentation.

Example Algorithm

The following example algorithm demonstrates how to use the `mlfinlab` library. The algorithm uses the `trend_scanning_labels` method to determine the trend direction of the Bitcoin-USD pair. If Bitcoin is in an uptrend, the algorithm allocations 100% of the portfolio to Bitcoin. Otherwise, it holds USD. The algorithm achieves a 1.79 Sharpe ratio, outperforming Bitcoin buy-and-hold, which achieves a 1.26 Sharpe ratio over the same time period.



Support

After you purchase MlFinLab, you get access to the Hudson and Thames Slack Community, where you and other quants can answer questions. Hudson and Thames also provide support under consulting.

FAQs

Note the following frequently asked questsions.

How do I install MlFinLab on QuantConnect?

To use MlFinLab on QuantConnect, see Import Libraries .

How do I install MlFinLab on my local machine?

To use MlFinLab on your local machine, see the Client Documentation that Hudson & Thames provides to avoid dependency issues. You receive the MlFinLab Client documentation after your purchase is successful.

Are the Jupyter Notebooks downloadable?

Yes, you can access the notebooks via the Client Documentation and download them.

Does Hudson & Thames provide support?

Yes, they provide support under consulting and you can ask their community on Slack if you have a question.

Popular Libraries

PyTorch

Introduction

This page explains how to build, train, deploy and store `PyTorch` models.

Import Libraries

Import the `torch` and `joblib` libraries.

```
PY
from AlgorithmImports import *
import torch
from torch import nn
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `torch` model and make predictions.

```
PY
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

Build Models

In this example, build a neural-network regression model that uses the following features and labels:

Data Category	Description
Features	The last 5 closing prices.
Labels	The following day's closing price

The following image shows the time difference between the features and labels:

Follow these steps to create a method to build the model:

1. Define a subclass of `nn.Module` to be the model.

   In this example, use the ReLU activation function for each layer.

```
class NeuralNetwork(nn.Module):
    # Model Structure
    def __init__(self):
        super(NeuralNetwork, self).__init__()
        self.flatten = nn.Flatten()
        self.linear_relu_stack = nn.Sequential(
            nn.Linear(5, 5),    # input size, output size of the layer
            nn.ReLU(),          # Relu non-linear transformation
            nn.Linear(5, 5),
            nn.ReLU(),
            nn.Linear(5, 1),    # Output size = 1 for regression
        )

    # Feed-forward training/prediction
    def forward(self, x):
        x = torch.from_numpy(x).float()   # Convert to tensor in type float
        result = self.linear_relu_stack(x)
        return result
```

2. Create an instance of the model and set its configuration to train on the GPU if it's available.

```
device = 'cuda' if torch.cuda.is_available() else 'cpu'
self.model = NeuralNetwork().to(device)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
training_length = 252*2
self.training_data = RollingWindow[float](training_length)
history = self.History[TradeBar](self.symbol, training_length, Resolution.Daily)
for trade_bar in history:
    self.training_data.Add(trade_bar.Close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
def get_features_and_labels(self, n_steps=5):
    close_prices = list(self.training_data)[::-1]

    features = []
    labels = []
    for i in range(len(close_prices)-n_steps):
        features.append(close_prices[i:i+n_steps])
        labels.append(close_prices[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()

    # Set the loss and optimization functions
    # In this example, use the mean squared error as the loss function and stochastic gradient descent as
the optimizer
    loss_fn = nn.MSELoss()
    learning_rate = 0.001
    optimizer = torch.optim.SGD(self.model.parameters(), lr=learning_rate)

    # Create a for-loop to train for preset number of epoch
    epochs = 5
    for t in range(epochs):
        # Create a for-loop to fit the model per batch
        for batch, (feature, label) in enumerate(zip(features, labels)):
            # Compute prediction and loss
            pred = self.model(feature)
            real = torch.from_numpy(np.array(label).flatten()).float()
            loss = loss_fn(pred, real)

            # Perform backpropagation
            optimizer.zero_grad()
            loss.backward()
            optimizer.step()
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
PY
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol].Close)
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and pass it to the model.

```
PY
features, __ = self.get_features_and_labels()
prediction = self.model(features[-1].reshape(1, -1))
prediction = float(prediction.detach().numpy()[-1])
```

You can use the label prediction to place orders.

```
PY
if prediction > slice[self.symbol].Price:
    self.SetHoldings(self.symbol, 1)
elif prediction < slice[self.symbol].Price:
    self.SetHoldings(self.symbol, -1)
```

Save Models

Follow these steps to save `PyTorch` models into the ObjectStore :

1. Set the key name of the model to be stored in the ObjectStore.

   ```
   PY
   model_key = "model"
   ```

2. Call the `GetFilePath` method with the key.

   ```
   PY
   file_name = self.ObjectStore.GetFilePath(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   ```
   PY
   joblib.dump(self.model, file_name)
   ```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

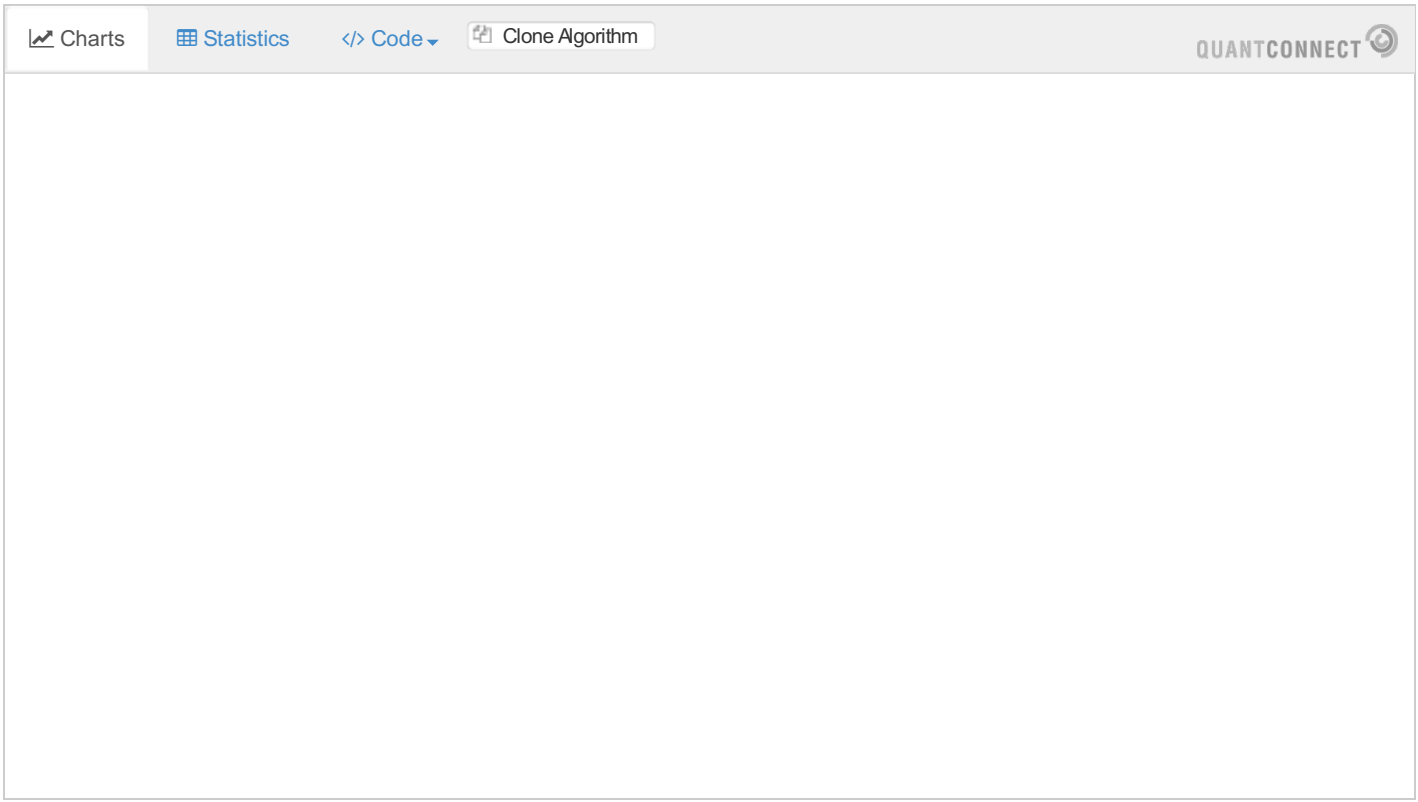
Load Models

You can load and trade with pre-trained `PyTorch` models that you saved in the ObjectStore. To load a `PyTorch` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

```py
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(model_key):
        file_name = self.ObjectStore.GetFilePath(model_key)
        self.model = joblib.load(file_name)
```

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the ObjectStore. If the ObjectStore does not contain the `model_key` , save the model using the `model_key` before you proceed.

Clone Example Algorithm



Popular Libraries

Scikit-Learn

Introduction

This page explains how to build, train, deploy and store `Scikit-Learn` models.

Import Libraries

Import the `sklearn` and `joblib` libraries.

```
PY
from AlgorithmImports import *
from sklearn.svm import SVR
from sklearn.model_selection import GridSearchCV
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `sklearn` model and make predictions.

```
PY
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

Build Models

In this example, build a support vector regression prediction model that uses the following features and labels:

Data Category	Description
Features	Daily percent change of the open, high, low, close, and volume of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

To build the model, call the `GridSearchCV` constructor with the SVR model, the parameter grid, a scoring method, the number of cross-validation folds:

```
PY
param_grid = {'C': [.05, .1, .5, 1, 5, 10],
              'epsilon': [0.001, 0.005, 0.01, 0.05, 0.1],
              'gamma': ['auto', 'scale']}
self.model = GridSearchCV(SVR(), param_grid, scoring='neg_mean_squared_error', cv=5)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
PY
training_length = 252*2
self.training_data = RollingWindow[TradeBar](training_length)
history = self.History[TradeBar](self.symbol, training_length, Resolution.Daily)
for trade_bar in history:
    self.training_data.Add(trade_bar)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
def get_features_and_labels(self, n_steps=5):
    training_df = self.PandasConverter.GetDataFrame[TradeBar](list(self.training_data)[::-1])
    daily_pct_change = training_df.pct_change().dropna()

    features = []
    labels = []
    for i in range(len(daily_pct_change)-n_steps):
        features.append(daily_pct_change.iloc[i:i+n_steps].values.flatten())
        labels.append(daily_pct_change['close'].iloc[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()
    self.model = self.model.fit(features, labels).best_estimator_
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol])
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

```
features, _ = self.get_features_and_labels()
prediction = self.model.predict(features[-1].reshape(1, -1))
prediction = float(prediction)
```

You can use the label prediction to place orders.

```py
if prediction > 0:
    self.SetHoldings(self.symbol, 1)
elif prediction < 0:
    self.SetHoldings(self.symbol, -1)
```

Save Models

Follow these steps to save `sklearn` models into the ObjectStore :

1. Set the key name you want to store the model under in the ObjectStore.

   ```py
   model_key = "model"
   ```

2. Call the `GetFilePath` method with the key.

   ```py
   file_name = self.ObjectStore.GetFilePath(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   ```py
   joblib.dump(self.model, file_name)
   ```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

You can load and trade with pre-trained `sklearn` models that you saved in the ObjectStore. To load a `sklearn` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

```py
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(model_key):
        file_name = self.ObjectStore.GetFilePath(model_key)
        self.model = joblib.load(file_name)
```

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the ObjectStore. If the ObjectStore does not contain the `model_key` , save the model using the `model_key` before you proceed.

Stable Baselines

Introduction

This page explains how to build, train, deploy and store `stable baselines 3` models.

Import Libraries

Import the `gym` and `stable_baselines3` libraries.

```
PY
from AlgorithmImports import *
import gym
from stable_baselines3 import DQN
```

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `stable_baselines` model and make predictions.

```
PY
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

Build Models

In this example, create a `gym` environment to initialize the training environment, agent, and reward. Then, create a reinforcement learning model by a single-asset deep Q-network learning algorithm using the following observations and rewards:

Data Category	Description
Observations	The 5-day open, high, low, close, and volume (OHLCV) of the SPY
Rewards	Maximum portfolio return

Follow these steps to create a method to build the model:

1. Create a custom `gym` environment class.

   In this example, create a custom environment with the previous 5 OHLCV log-return data as observation and the highest portfolio value as reward.

```
PY
class TradingEnv(gym.Env):
    FLAT = 0
    LONG = 1
    SHORT = 2

    def __init__(self, ohlcv, ret):
        super(TradingEnv, self).__init__()

        self.ohlcv = ohlcv
        self.ret = ret
        self.trading_cost = 0.01
        self.reward = 1

        # The number of step the training has taken, starts at 5 since we're using the previous 5
data for observation.
        self.current_step = 5
        # The last action
        self.last_action = 0

        # Define action and observation space
        # Example when using discrete actions, we have 3: LONG, SHORT and FLAT.
        n_actions = 3
        self.action_space = gym.spaces.Discrete(n_actions)
        # The observation will be the coordinate of the agent, shape for (5 previous data poionts,
OHLCV)
        self.observation_space = gym.spaces.Box(low=-2, high=2, shape=(5, 5, 5), dtype=np.float64)

    def reset(self):
        # Reset the number of step the training has taken
        self.current_step = 5
        # Reset the last action
        self.last_action = 0
        # must return np.array type
        return self.ohlcv[self.current_step-5:self.current_step].astype(np.float32)

    def step(self, action):
        if action == self.LONG:
            self.reward *= 1 + self.ret[self.current_step] - (self.trading_cost if self.last_action
!= action else 0)
        elif action == self.SHORT:
            self.reward *= 1 + -1 * self.ret[self.current_step] - (self.trading_cost if
self.last_action != action else 0)
        elif action == self.FLAT:
                self.reward *= 1 - (self.trading_cost if self.last_action != action else 0)
        else:
            raise ValueError("Received invalid action={} which is not part of the action
space".format(action))

        self.last_action = action
        self.current_step += 1

        # Have we iterate all data points?
        done = (self.current_step == self.ret.shape[0]-1)

        # Reward as return
        return self.ohlcv[self.current_step-5:self.current_step].astype(np.float32), self.reward,
done, {}
```

2. Get the processed training data.

```
PY
obs, rewards = self.get_observations_and_rewards()
```

3. Initialize the environment with the observations and results.

```
PY
self.env = TradingEnv(obs, rewards)
```

4. Call the `DQN` constructor with the learning policy and the `gym` environment.

```
PY
self.model = DQN(MlpPolicy, env)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
PY
training_length = 252*2
self.training_data = RollingWindow[TradeBar](training_length)
history = self.History[TradeBar](self.spy, training_length, Resolution.Daily)
for trade_bar in history:
    self.training_data.Add(trade_bar)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
PY
def get_observations_and_rewards(self, n_step=5):
    training_df = self.PandasConverter.GetDataFrame[TradeBar](list(self.training_data)[::-1])
    daily_pct_change = training_df['close'].pct_change().dropna()

    obs = []
    rewards = []
    for i in range(len(daily_pct_change)-n_step):
        obs.append(training_df.iloc[i:i+n_step].values)
        rewards.append(float(daily_pct_change.iloc[i+n_step]))
    obs = np.array(obs)
    rewards = np.array(rewards)

    return obs, rewards

def my_training_method(self):
    obs, rewards = self.get_observations_and_rewards()
    self.env = TradingEnv(obs, rewards)
    self.model = DQN("MlpPolicy", self.env)
    self.model.learn(total_timesteps=500)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
PY
self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol])
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

```
features, _ = self.get_observations_and_rewards()
action, _ = self.model.predict(features[-5:], deterministic=True)
_, _, _, _ = self.env.step(action)
```

You can use the label prediction to place orders.

```
if action == 0:
    self.Liquidate(self.spy)
elif action == 1:
    self.SetHoldings(self.spy, 1)
elif action == 2:
    self.SetHoldings(self.spy, -1)
```

Save Models

Follow these steps to save `stable_baselines` models into the ObjectStore :

1. Set the key name of the model to be stored in the ObjectStore.

   ```
   model_key = "model"
   ```

2. Call the `GetFilePath` method with the key.

   ```
   file_name = self.ObjectStore.GetFilePath(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `save` method the file path.

```
    self.model.save(file_name)
```

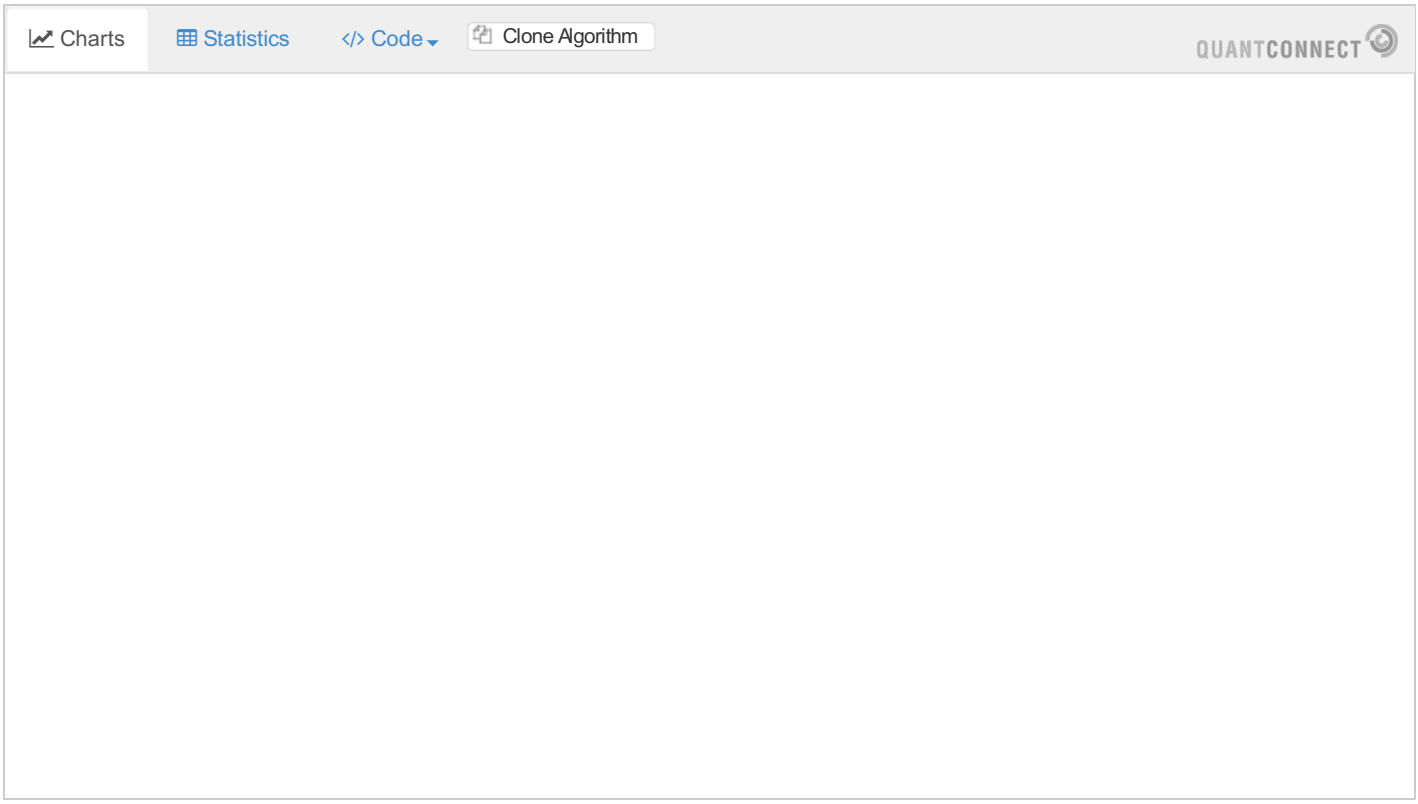
Load Models

You can load and trade with pre-trained `keras` models that you saved in the ObjectStore. To load a `keras` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `load_model` method.

```
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(model_key):
        file_name = self.ObjectStore.GetFilePath(model_key)
        self.model = DQN.load(file_name, env=env)
```

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the ObjectStore. If the ObjectStore does not contain the `model_key` , save the model using the `model_key` before you proceed.

Clone Example Algorithm



Popular Libraries

Tensorflow

Introduction

This page explains how to build, train, deploy and store `Tensorflow` v1 models. To view the tutorial on Tensorflow 2, see Keras .

Import Libraries

Import the `tensorflow` libraries.

```
PY
from AlgorithmImports import *
import tensorflow.compat.v1 as tf
from google.protobuf import json_format
import json5

tf.disable_v2_behavior()
```

You need the `google.protobuf` and `json5` libraries to store and load models.

Disable `tensorflow` v2 behaviors in order to deploy a v1 model.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `tensorflow` model and make predictions.

```
PY
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

Build Models

In this example, build a neural-network regression prediction model that uses the following features and labels:

Data Category	Description
Features	The last 5 closing prices
Labels	The following day's closing price

The following image shows the time difference between the features and labels:

Follow these steps to create a method to build the model:

1. Create a method to build the model for the algorithm class.

```PY
def BuildModel(self):
    # Instantiate a tensorflow session
    sess = tf.Session()

    # Declare the number of factors and then create placeholders for the input and output layers.
    num_factors = 5
    X = tf.placeholder(dtype=tf.float32, shape=[None, num_factors], name='X')
    Y = tf.placeholder(dtype=tf.float32, shape=[None])

    # Set up the weights and bias initializers for each layer.
    weight_initializer = tf.variance_scaling_initializer(mode="fan_avg", distribution="uniform",
scale=1)
    bias_initializer = tf.zeros_initializer()

    # Create hidden layers that use the Relu activator.
    num_neurons_1 = 32
    num_neurons_2 = 16
    num_neurons_3 = 8

    W_hidden_1 = tf.Variable(weight_initializer([num_factors, num_neurons_1]))
    bias_hidden_1 = tf.Variable(bias_initializer([num_neurons_1]))
    hidden_1 = tf.nn.relu(tf.add(tf.matmul(X, W_hidden_1), bias_hidden_1))

    W_hidden_2 = tf.Variable(weight_initializer([num_neurons_1, num_neurons_2]))
    bias_hidden_2 = tf.Variable(bias_initializer([num_neurons_2]))
    hidden_2 = tf.nn.relu(tf.add(tf.matmul(hidden_1, W_hidden_2), bias_hidden_2))

    W_hidden_3 = tf.Variable(weight_initializer([num_neurons_2, num_neurons_3]))
    bias_hidden_3 = tf.Variable(bias_initializer([num_neurons_3]))
    hidden_3 = tf.nn.relu(tf.add(tf.matmul(hidden_2, W_hidden_3), bias_hidden_3))

    # Create the output layer and give it a name, so it is accessible after saving and loading the
model.
    W_out = tf.Variable(weight_initializer([num_neurons_3, 1]))
    bias_out = tf.Variable(bias_initializer([1]))
    output = tf.transpose(tf.add(tf.matmul(hidden_3, W_out), bias_out), name='outer')

    # Set up the loss function and optimizers for gradient descent optimization and backpropagation.
    # This example uses mean-square error as the loss function because the close price is a
continuous data and uses Adam as the optimizer because of its adaptive step size.
    loss = tf.reduce_mean(tf.squared_difference(output, Y))
    optimizer = tf.train.AdamOptimizer().minimize(loss)

    return sess, X, Y, output, optimizer
```

2. Instantiate the model, input layers, output layer, and optimizer and then save them as class variables.

```
PY
self.model, self.X, self.Y, self.output, self.optimizer = self.BuildModel(features, labels)
```

3. Call the `run` method with the result from the `global_variables_initializer` method.

```
PY
self.model.run(tf.global_variables_initializer())
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
PY
training_length = 252*2
self.training_data = RollingWindow[float](training_length)
history = self.History[TradeBar](self.symbol, training_length, Resolution.Daily)
for trade_bar in history:
    self.training_data.Add(trade_bar.Close)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
PY
def get_features_and_labels(self, n_steps=5):
    close_prices = list(self.training_data)[::-1]

    features = []
    labels = []
    for i in range(len(close_prices)-n_steps):
        features.append(close_prices[i:i+n_steps])
        labels.append(close_prices[i+n_steps])
    features = np.array(features)
    labels = np.array(labels)

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()
    self.model.run(self.optimizer, feed_dict={self.X: features, self.Y: labels})
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
PY
self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current close price to the `RollingWindow` that holds the training data.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol].Close)
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `run` method with new features.

```
new_features, __ = self.get_features_and_labels()
prediction = self.model.run(self.output, feed_dict={self.X: new_features[-1].reshape(1, -1)})
prediction = float(prediction.flatten()[-1])
```

You can use the label prediction to place orders.

```
if prediction > slice[self.symbol].Price:
    self.SetHoldings(self.symbol, 1)
else:
    self.SetHoldings(self.symbol, -1)
```

Save Models

Follow these steps to save `Tensorflow` models into the ObjectStore :

1. Export the `TensorFlow` graph as a JSON object.

   ```
   graph_definition = tf.compat.v1.train.export_meta_graph()
   json_graph = json_format.MessageToJson(graph_definition)
   ```

2. Export the `TensorFlow` weights as a JSON object.

   ```
   weights = self.model.run(tf.compat.v1.trainable_variables())
   weights = [w.tolist() for w in weights]
   json_weights = json5.dumps(weights)
   ```

3. Save the graph and weights to the `ObjectStore` .

```
PY

    self.ObjectStore.Save('graph', json_graph)
    self.ObjectStore.Save('weights', json_weights)
```

Load Models

You can load and trade with pre-trained `tensorflow` models that you saved in the ObjectStore. To load a `tensorflow` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then recall the graph and weights of the model.

```
PY

def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey('graph') and self.ObjectStore.ContainsKey('weights'):
        json_graph = self.ObjectStore.Read('graph')
        json_weights = self.ObjectStore.Read('weights')

        # Restore the tensorflow graph from JSON objects
        tf.reset_default_graph()
        graph_definition = json_format.Parse(json_graph, tf.MetaGraphDef())
        self.model = tf.Session()
        tf.train.import_meta_graph(graph_definition)

        # Select the input, output tensors and optimizer
        self.X = tf.get_default_graph().get_tensor_by_name('X:0')
        self.Y = tf.get_default_graph().get_tensor_by_name('Y:0')
        self.output = tf.get_default_graph().get_tensor_by_name('outer:0')
        self.optimizer = tf.get_default_graph().get_collection('Variable/Adam')

        # Restore the model weights from the JSON object.
        weights = [np.asarray(x) for x in json5.loads(json_weights)]
        assign_ops = []
        feed_dict = {}
        vs = tf.trainable_variables()
        zipped_values = zip(vs, weights)
        for var, value in zipped_values:
            value = np.asarray(value)
            assign_placeholder = tf.placeholder(var.dtype, shape=value.shape)
            assign_op = var.assign(assign_placeholder)
            assign_ops.append(assign_op)
            feed_dict[assign_placeholder] = value
        self.model.run(assign_ops, feed_dict=feed_dict)
```

The `ContainsKey` method returns a boolean that represents if the `graph` and `weights` is in the ObjectStore. If the ObjectStore does not contain the keys, save the model using them before you proceed.

Popular Libraries

Tslearn

Introduction

This page explains how to build, train, deploy and store `Tslearn` models.

Import Libraries

Import the `tslearn` libraries.

```
PY
from AlgorithmImports import *
from tslearn.barycenters import softdtw_barycenter
from tslearn.clustering import TimeSeriesKMeans
```

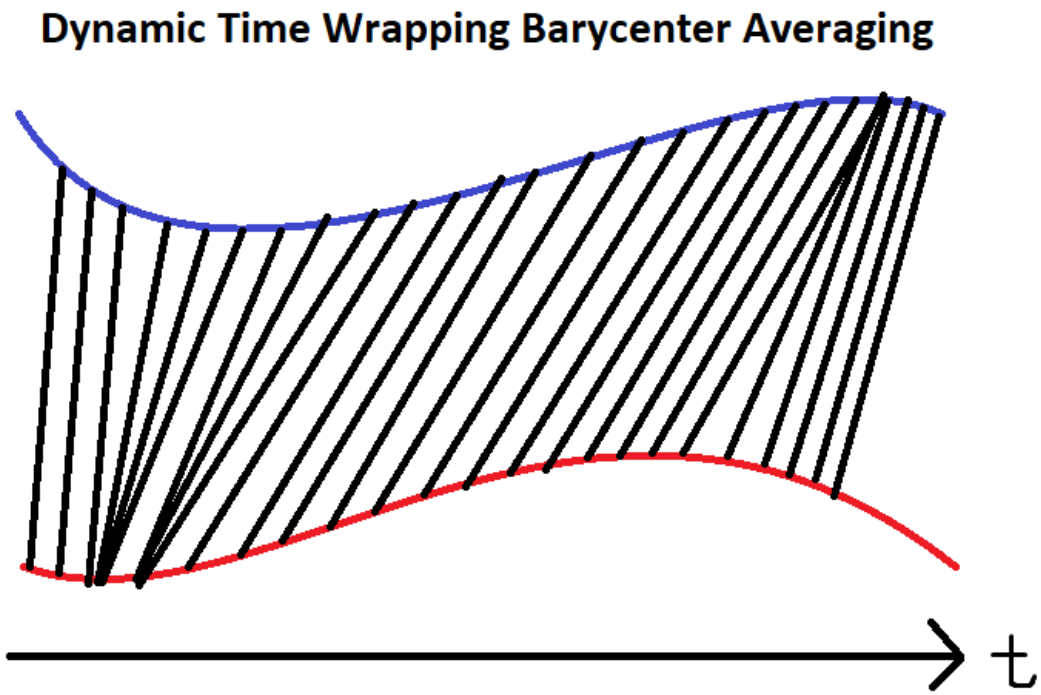
Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `tslearn` model.

```
PY
tickers = ["SPY", "QQQ", "DIA",
           "AAPL", "MSFT", "TSLA",
           "IEF", "TLT", "SHV", "SHY",
           "GLD", "IAU", "SLV",
           "USO", "XLE", "XOM"]
symbols = [self.AddEquity(ticker, Resolution.Daily).Symbol for ticker in tickers]
```

Build Models

In this example, train a model that clusters the universe of Equities into distinct groups and then allocate an equal portion of the portfolio to each cluster. To cluster the securities, instead of using a real-time comparison, apply Dynamic Time Wrapping Barycenter Averaging (DBA) to their historical prices and then run a k-means clustering algorithm. DBA is a technique of averaging a few time-series into a single one without losing much of their information. Since not all time-series move efficiently like in ideal EMH assumption, this technique allows similarity analysis of different time-series with sticky lags. The following image shows a visualization of the process. For more information about the technical details, see Dynamic Time Warping in the tslearn documentation .



To perform DBA and then cluster the securities by k-means, create a TimeSeriesKMeans model:

```
PY
self.model = TimeSeriesKMeans(n_clusters=6,   # We have 6 main groups
                    metric="dtw")
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
PY
training_length = 252
self.training_data = {}
history = self.History(self.symbols, training_length, Resolution.Daily).unstack(0).close
for symbol in self.symbols:
    self.training_data[symbol] = RollingWindow[float](training_length)
    for close_price in history[symbol]:
        self.training_data[symbol].Add(close_price)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
def get_features(self):
    close_price = pd.DataFrame({symbol: list(data)[::-1] for symbol, data in self.training_data.items()})
    log_price = np.log(close_price)
    log_normal_price = (log_price - log_price.mean()) / log_price.std()

    return log_normal_price

def my_training_method(self):
    features = self.get_features()
    self.model.fit(features.T.values)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
def OnData(self, slice: Slice) -> None:
    for kvp in slice.Bars:
        self.training_data[kvp.Key].Add(kvp.Value.Close)
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

```
features = self.get_features()
self.labels = self.model.predict(features.T.values)
```

You can use the label prediction to place orders.

```
for i in set(self.labels):
    assets_in_cluster = features.columns[[n for n, k in enumerate(self.labels) if k == i]]
    size = 1/6/len(assets_in_cluster)
    self.SetHoldings([PortfolioTarget(symbol, size) for symbol in assets_in_cluster])
```

Save Models

Follow these steps to save `tslearn` models into the ObjectStore :

1. Set the key name of the model to be stored in the ObjectStore.

```
model_key = "model"
```

2. Call the `GetFilePath` method with the key.

```
file_name = self.ObjectStore.GetFilePath(model_key)
```

   This method returns the file path where the model will be stored.

3. Call the `to_hdf5` method with the file path.

```
self.model.to_hdf5(file_name + ".hdf5")
```

Load Models

You can load and trade with pre-trained `tslearn` models that saved in ObjectStore. To load a `tslearn` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `from_hdf5` method.

```
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(model_key):
        file_name = self.ObjectStore.GetFilePath(model_key)
        self.model = TimeSeriesKMeans.from_hdf5(file_name + ".hdf5")
```

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the ObjectStore. If the ObjectStore does not contain the `model_key` , save the model using the `model_key` before you proceed.

    labels = np.array(labels)
    features = (features - features.mean()) / features.std()
    labels = (labels - labels.mean()) / labels.std()

    d_matrix = xgb.DMatrix(features, label=labels)

    return d_matrix

def my_training_method(self):
    d_matrix = self.get_features_and_labels()
    params = {
        'booster': 'gbtree',
        'colsample_bynode': 0.8,
        'learning_rate': 0.1,
        'lambda': 0.1,
        'max_depth': 5,
        'num_parallel_tree': 100,
        'objective': 'reg:squarederror',
        'subsample': 0.8,
      }
    self.model = xgb.train(params, d_matrix, num_boost_round=10)
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
PY

self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
PY

# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
PY

def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol].Close)
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

```
new_d_matrix = self.get_features_and_labels(df)
prediction = self.model.predict(new_d_matrix)
prediction = prediction.flatten()
```

You can use the label prediction to place orders.

```
if float(prediction[-1]) > float(prediction[-2]):
    self.SetHoldings(self.symbol, 1)
else:
    self.SetHoldings(self.symbol, -1)
```

Save Models

Follow these steps to save `xgboost` models into the ObjectStore :

1. Set the key name of the model to be stored in the ObjectStore.

   ```
   model_key = "model"
   ```

2. Call the `GetFilePath` method with the key.

   ```
   file_name = self.ObjectStore.GetFilePath(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   ```
   joblib.dump(self.model, file_name)
   ```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

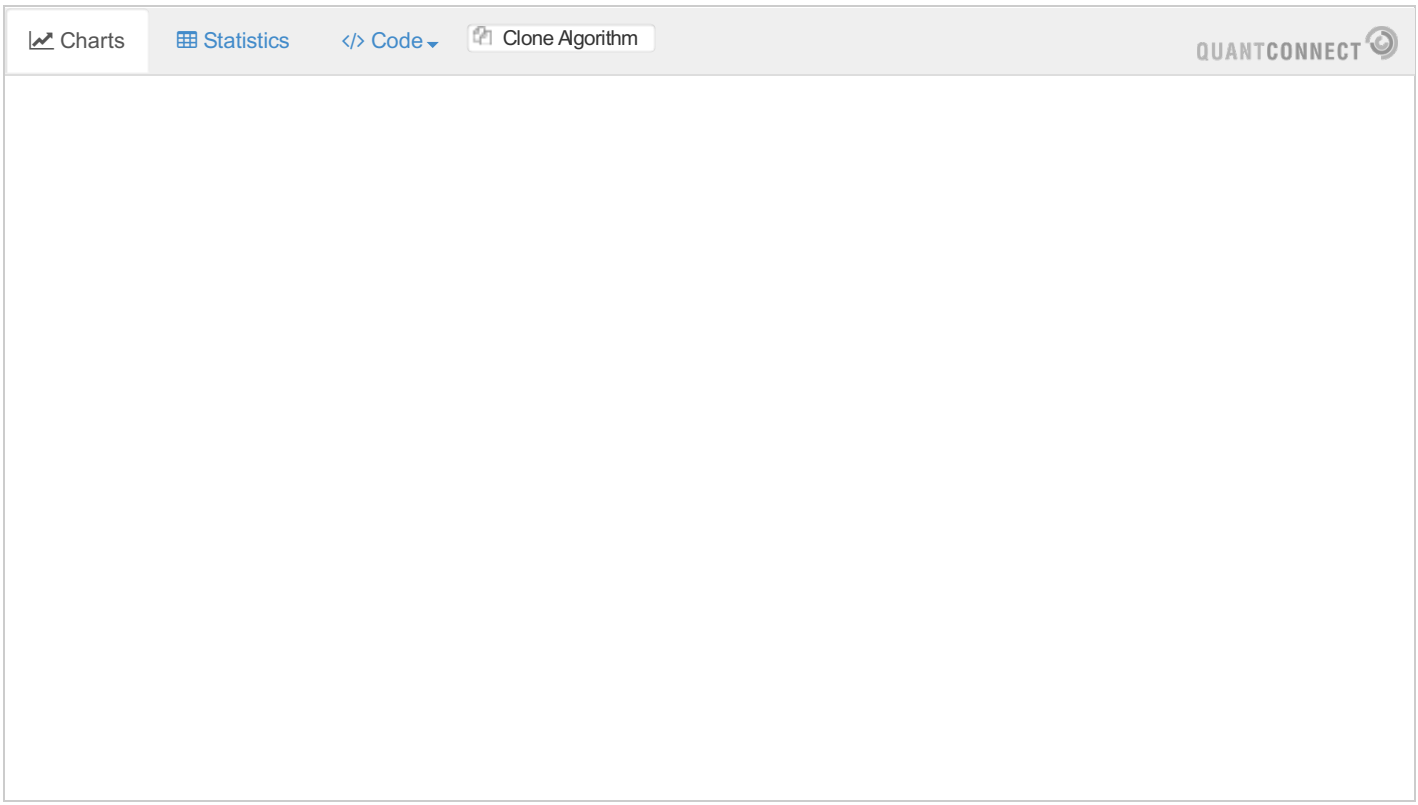
You can load and trade with pre-trained `xgboost` models that saved in ObjectStore. To load a `xgboost` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

```
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(model_key):
        file_name = self.ObjectStore.GetFilePath(model_key)
        self.model = joblib.load(file_name)
```

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the ObjectStore. If the ObjectStore

does not contain the `model_key` , save the model using the `model_key` before you proceed.

Clone Example Algorithm



Popular Libraries

Aesera

Introduction

This page explains how to build, train, deploy and store `Aesera` models.

Import Libraries

Import the `aesera` and `sklearn` libraries.

```
PY
from AlgorithmImports import *
import aesara
import aesara.tensor as at
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import MinMaxScaler
import joblib
```

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `sklearn` model and make predictions.

```
PY
self.symbol = self.AddEquity("SPY", Resolution.Daily).Symbol
```

Build Models

In this example, build a logistic regression prediction model that uses the following features and labels:

Data Category	Description
Features	Normalized daily close price of the SPY over the last 5 days
Labels	Return direction of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow the below steps to build the model:

1. Initialize variables.

```
PY

# Declare Aesara symbolic variables
x = at.dmatrix("x")
y = at.dvector("y")

# initialize the weight vector w randomly using share so model coefficients keep their values
# between training iterations (updates)
rng = np.random.default_rng(100)
w = aesara.shared(rng.standard_normal(5), name="w")

# initialize the bias term
b = aesara.shared(0., name="b")
```

2. Construct the model graph.

```
PY

# Construct Aesara expression graph
p_1 = 1 / (1 + at.exp(-at.dot(x, w) - b))       # Logistic transformation
prediction = p_1 > 0.5                          # The prediction thresholded
xent = y * at.log(p_1) - (1 - y) * at.log(1 - p_1)  # Cross-entropy log-loss function
cost = xent.mean() + 0.01 * (w ** 2).sum()      # The cost to minimize (MSE)
gw, gb = at.grad(cost, [w, b])                  # Compute the gradient of the cost
```

3. Compile the model.

```
PY

self.train = aesara.function(
          inputs=[x, y],
          outputs=[prediction, xent],
          updates=((w, w - 0.1 * gw), (b, b - 0.1 * gb)))
self.predict = aesara.function(inputs=[x], outputs=prediction)
```

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

```
PY

training_length = 252*2
self.training_data = RollingWindow[TradeBar](training_length)
history = self.History[TradeBar](self.symbol, training_length, Resolution.Daily)
for trade_bar in history:
    self.training_data.Add(trade_bar)
```

Define a Training Method

To train the model, define a method that fits the model with the training data.

```
PY

def get_features_and_labels(self, n_steps=5):
    training_df = self.PandasConverter.GetDataFrame[TradeBar](list(self.training_data)[::-1])['close']

    features = []
    for i in range(1, n_steps + 1):
        close = training_df.shift(i)[n_steps:-1]
        close.name = f"close-{i}"
        features.append(close)
    features = pd.concat(features, axis=1)
    # Normalize using the 5 day interval
    features = MinMaxScaler().fit_transform(features.T).T[4:]

    Y = training_df.pct_change().shift(-1)[n_steps*2-1:-1].reset_index(drop=True)
    labels = np.array([1 if y > 0 else 0 for y in Y])   # binary class

    return features, labels

def my_training_method(self):
    features, labels = self.get_features_and_labels()
    D = (features, labels)
    self.train(D[0], D[1])
```

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

```
PY

self.Train(self.my_training_method)
```

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

```
PY

# Train the model every Sunday at 8:00 AM
self.Train(self.DateRules.Every(DayOfWeek.Sunday), self.TimeRules.At(8, 0), self.my_training_method)
```

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

```
def OnData(self, slice: Slice) -> None:
    if self.symbol in slice.Bars:
        self.training_data.Add(slice.Bars[self.symbol])
```

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

```
features, _ = self.get_features_and_labels()
prediction = self.predict(features[-1].reshape(1, -1))
prediction = float(prediction)
```

You can use the label prediction to place orders.

```
if prediction == 1:
    self.SetHoldings(self.symbol, 1)
elif prediction == 0:
    self.SetHoldings(self.symbol, -1)
```

Save Models

Follow these steps to save `sklearn` models into the ObjectStore :

1. Set the key name you want to store the model under in the ObjectStore.

   ```
   model_key = "model"
   ```

2. Call the `GetFilePath` method with the key.

   ```
   file_name = self.ObjectStore.GetFilePath(model_key)
   ```

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   ```
   joblib.dump(self.predict, file_name)
   ```

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

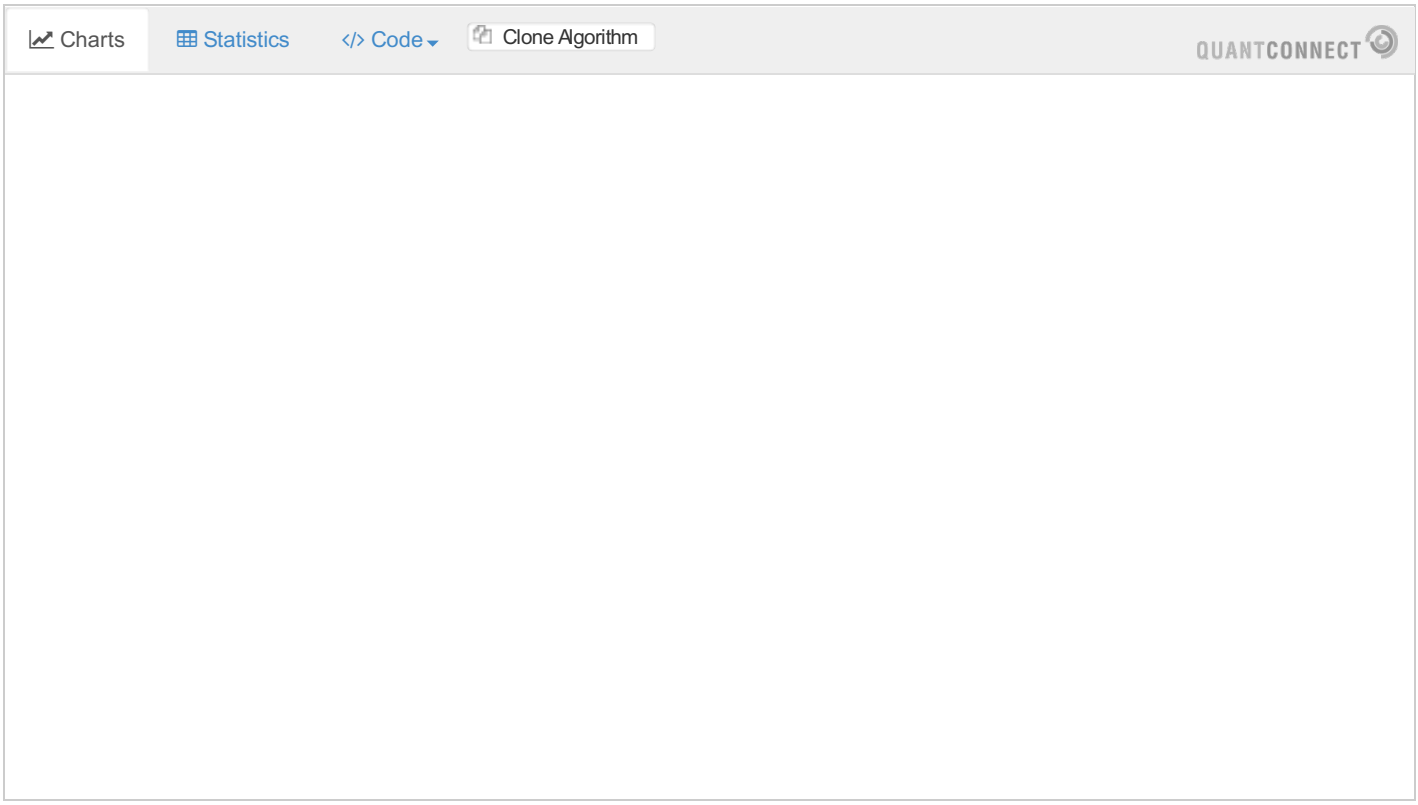
Load Models

You can load and trade with pre-trained `sklearn` models that you saved in the ObjectStore. To load a `sklearn` model from the ObjectStore, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

```
def Initialize(self) -> None:
    if self.ObjectStore.ContainsKey(model_key):
        file_name = self.ObjectStore.GetFilePath(model_key)
        self.model = joblib.load(file_name)
```

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the ObjectStore. If the ObjectStore does not contain the `model_key` , save the model using the `model_key` before you proceed.

Clone Example Algorithm



Algorithm Framework

Algorithm Framework

Overview

Introduction

Since QuantConnect was formed in 2013, the community has created more than 2 million algorithms. Although they all seek to achieve different results, they can all be abstracted into the same core features. The Algorithm Framework is our attempt to provide this well-defined structure to the community, encouraging good design and making your work more reusable. LEAN provides many pre-built Algorithm Framework models you can use in your algorithms.

Strategy Styles

The algorithm framework works best for portfolio rebalancing, ranking, and multi-factor style strategies. The default portfolio construction models are designed to weigh and invest in the assets as the signals values shift, aiming to be fully invested as much as possible.

Some strategies might find it difficult to fit this model. Technical entry signals are often tightly coupled with their exit criteria, they may not have defined hold periods, and they might follow the market to determine when to exit. This style of strategy can be addressed in a few ways:

1. Short Term Signals - Emitting insights for short periods until they are no longer valid.
2. Cancel Signals - Updating an insight's expiry time so that it's expired upon the exit signal.
3. Alpha Exit Signal - Treating exit as its own signal, a separate Alpha model could indicate exit.
4. Risk Model - Tracking exit using a risk model that attempts to lock in gains.

These techniques are still not ideal for many strategies. For example, with only a single signal, the built in `EqualWeightingPortfolioConstructionModel` will allocate 100% of buying power to a single asset, over concentrating risk. If a second signal comes a few days later, it would sell 50% of the portfolio to free cash and invest in the second asset. This can create high trading costs through portfolio churn.

With a custom portfolio construction model , signals can mean what you need for your specific strategy style. For example, you might create a " `MultiBetPortfolioConstructionModel` " that uses each insight to open a specific "bet" that is separately allocated capital and tracked.

Important Terminology

The following table defines important Algorithm Framework terminology:

Term	Description
Universe Selection model	A framework module that selects assets for your algorithm.
Alpha model	A framework module that generates trading signals on the assets in your universe.
Insight	An object that represents a trading signal. The Alpha model generates these objects for the Portfolio Construction model.
Portfolio Construction model	A framework module that determines position size targets based on the `Insight` objects it receives from the Alpha model.
PortfolioTarget	An object that represents the target position size for an asset in the universe. The Portfolio Construction model generates these objects for the Risk Management model.
Risk Management	A framework module that manages market risks and ensures the algorithm remains within target parameters. This model adjusts the `PortfolioTarget` objects it receives from the Portfolio Construction model before they reach the Execution model.
Execution	A framework module that places trades to reach the target risk-adjust portfolio based on the `PortfolioTarget` objects it receives from the Risk Management model.

Framework Advantages

We recommend you design strategies with the Algorithm Framework in most cases. The Algorithm Framework has many advantages over the classic algorithm design.

Pluggable Algorithm Modules

With the Algorithm Framework, your code can instantly utilize all modules built within the framework. The modules clip together in well-defined ways, which enable them to be shared and swapped interchangeably.

Focus On Your Strengths

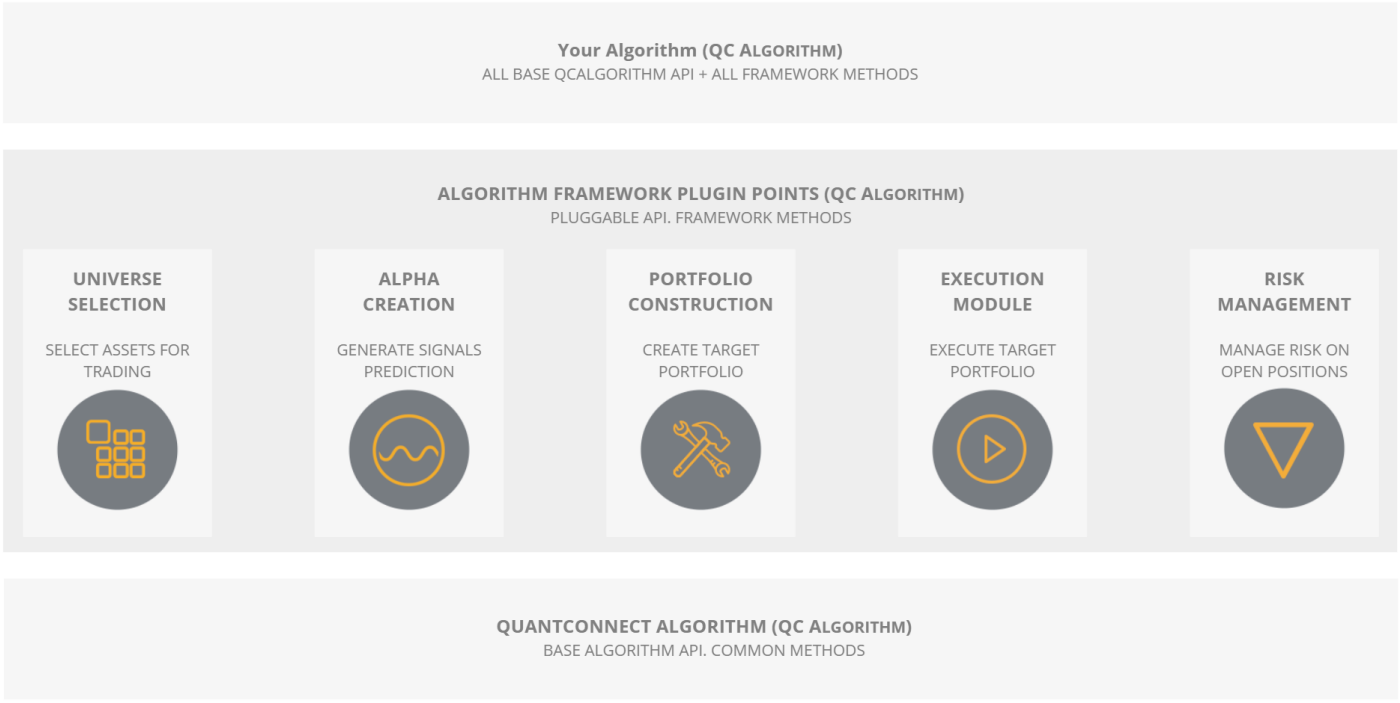
If you write code in modules, you can focus on your strengths. If you are great at building universes, you can build Universe Selection modules. If you have risk management experience, you could write reusable risk monitoring technology.

Reduce Development By Using Community Modules

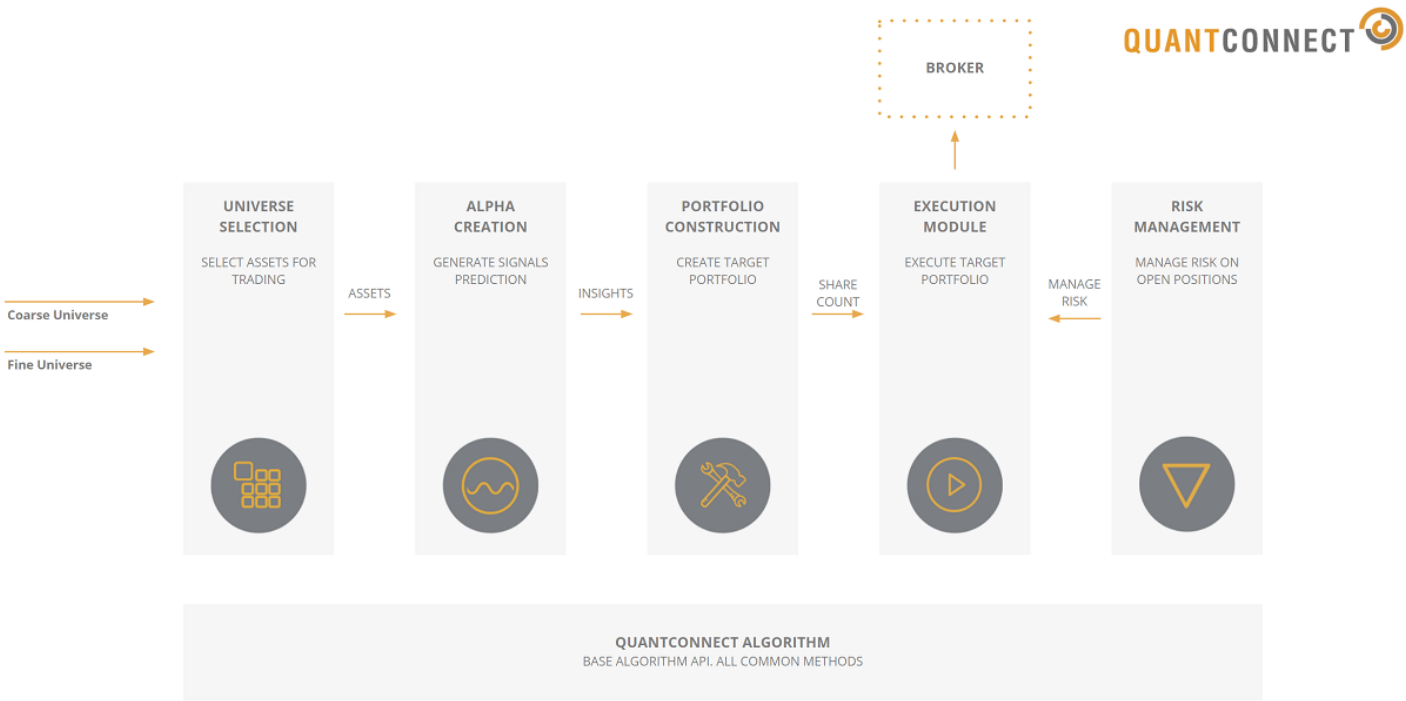
Easily share modules you've made between algorithms or pull in ones produced by the community. The strict separation of duties makes the Algorithm Framework perfect for reusing code between strategies.

System Architecture

The Algorithm Framework is built into the `QCAlgorithm` class, so your strategy can access all the normal methods you use for algorithm development. You should be able to copy and paste your algorithms across without any changes. You don't need a separate class.



The framework data output of each module flows into the following module. The assets that the Universe Selection model selects are fed into the Alpha model to generate trade signals (`Insight` objects). The `Insight` objects from the Alpha model are fed into the Portfolio Construction model to create `PortfolioTarget` objects, which contain the target number of units to hold for each asset. The `PortfolioTarget` objects from the Portfolio Construction model are fed into the Risk Management model to ensure the targets are within safe risk parameters and to adjust the `PortfolioTarget` objects if necessary. The `PortfolioTarget` objects from the Risk Management model are fed into the Execution model, which efficiently places trades to acquire the target portfolio.



```
class MyFrameworkAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetUniverseSelection()
        self.AddAlpha()
        self.SetPortfolioConstruction()
        self.SetExecution()
        self.AddRiskManagement()
```

PY

For simple strategies, it may seem like overkill to abstract out your algorithm concepts. However, even simple strategies can benefit from reusing the ecosystem of modules available in QuantConnect. Imagine pairing your EMA-cross Alpha model with a better execution system or plugging in an open-source trailing stop Risk Management model .

Separation of Concerns

The separation of concerns principle is an algorithm design principle where individual components are isolated and their responsibilities don't overlap. The Algorithm Framework is designed to uphold this design principle. The individual framework components shouldn't rely on the state of the other framework components in order to operate.

In the Algorithm Framework, the models should not communicate. The universe constituents and the `Insight` objects you emit should be the same, regardless of what you select for the Portfolio Construction, Risk Management, and Execution models. If your algorithm logic naturally violates the separation of concerns design principle, it's more appropriate to use the classic or hybrid design .

Framework vs Classic Design

Select the classic or Algorithm Framework design based on the needs of your algorithm. If your algorithm uses special order types or passes information between the different algorithm components, use the classic design. If you can reuse existing modules and the Algorithm Framework modules can work in isolation, use the Algorithm Framework design.

Algorithm Framework

Universe Selection

Universe Selection

Key Concepts

Introduction

The Universe Selection model creates `Universe` objects, which select the assets for your algorithm. As the universe changes, we notify your algorithm through the `OnSecuritiesChanged` event handler. With this event handler, you can track the current universe constituents in other parts of your algorithm without breaking the separation of concerns design principle.

Types of Universe Selection

We have identified several types of universes that cover most people's requirements and built helper classes to make their implementation easier. The following table describes the types of pre-built Universe Selection models:

Universe Type	Description
Manual Universes	Universes that use a fixed, static set of assets
Fundamental Universes	Universes for US Equities that are based on coarse price or fundamental data
Scheduled Universes	Universes that trigger on regular, custom intervals
Futures Universes	Universes that subscribe to Future chains
Option Universes	Universes that subscribe to Option chains

Add Models

To add a Universe Selection model, in the `Initialize` method, call the `AddUniverseSelection` method.

```
symbols = [Symbol.Create("SPY", SecurityType.Equity, Market.USA)]
self.AddUniverseSelection(ManualUniverseSelectionModel(symbols))
```

PY

To view all the pre-built Universe Selection models, see Types of Universe Selection .

Multi-Universe Algorithms

You can add multiple Universe Selection models to a single algorithm.

```
self.AddUniverseSelection(EmaCrossUniverseSelectionModel())
self.AddUniverseSelection(FineFundamentalUniverseSelectionModel(self.SelectCoarse, self.SelectFine))
```

If you add multiple Universe Selection models, the algorithm subscribes to the constituents of all the models.

Model Structure

Universe Selection models should extend the `UniverseSelectionModel` class. Extensions of the `UniverseSelectionModel` class must implement the `CreateUniverses` method, which receives an `algorithm` object and returns an array of `Universe` objects.

```
class MyUniverseSelectionModel(UniverseSelectionModel):

    # Creates the universes for this algorithm
    def CreateUniverses(self, algorithm: QCAlgorithm) -> List[Universe]:
        universes = []
        return universes

    # Gets the next time the framework should invoke the `CreateUniverses` method to refresh the set of
universes.
    def GetNextRefreshTimeUtc(self):
        return datetime.max
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

Generally, you should be able to extend one of the pre-built Universe Selection types. If you need to do something that doesn't fit into the pre-built types, let us know and we'll create a new foundational type of Universe Selection model.

Track Security Changes

When the Universe Selection model adjusts the universe constituents, we notify your algorithm through the `OnSecuritiesChanged` event handler on your other framework components. The method receives `QCAlgorithm` and `SecurityChanges` objects. The `QCAlgorithm` object is an instance of the base QCAlgorithm class, not a reference to your algorithm object. To access the added securities, check the `changes.AddedSecurities` property. To access the removed securities, check the `changes.RemovedSecurities` property.

```
def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
    for security in changes.AddedSecurities:
        self.Log(f"Added {security.Symbol}")

    for security in changes.RemovedSecurities:
        self.Log(f"Removed {security.Symbol}")
```

Live Trading Considerations

In live trading, the securities in your brokerage account are added to your user-defined universe. If your Universe Selection model doesn't select these securities, they are not removed from your user-defined universe. When you liquidate the positions, you can remove them from the user-defined universe. If you call the `RemoveSecurity` method, it automatically liquidates the position.

To see the securities in your user-defined universe that were loaded from your brokerage account, check your algorithm's ActiveSecurities in the OnWarmupFinished event handler.

Universe Selection

Universe Settings

Introduction

Universe settings and security initializers enable you to configure some properties of the securities in a universe.

Properties

The universe settings of your algorithm configure some properties of the universe constituents. The following table describes the properties of the `UniverseSettings` object:

Property: `ExtendedMarketHours` Should assets also feed extended market hours? You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily resolution, the daily bars only reflect the regular trading hours. Data Type: `bool` | Default Value: `False`
Property: `FillForward` Should asset data fill forward? Data Type: `bool` | Default Value: `True`
Property: `MinimumTimeInUniverse` What's the minimum time assets should be in the universe? Data Type: `timedelta` | Default Value: `timedelta(1)`
Property: `Resolution` What resolution should assets use? Data Type: `Resolution` | Default Value: `Resolution.Minute`

Property: `ContractDepthOffset`

What offset from the current front month should be used for continuous Future contracts ? 0 uses the front month and 1 uses the back month contract. This setting is only available for Future assets.

Data Type: `int` | Default Value: `0`

Property: `DataMappingMode`

How should continuous Future contracts be mapped? This setting is only available for Future assets.

Data Type: `DataMappingMode` | Default Value: `DataMappingMode.OpenInterest`

Property: `DataNormalizationMode`

How should historical prices be adjusted? This setting is only available for Equity and Futures assets.

Data Type: `DataNormalizationMode` | Default Value: `DataNormalizationMode.Adjusted`

Property: `Leverage`

What leverage should assets use in the universe? This setting is not available for derivative assets.

Data Type: `float` | Default Value: `Security.NullLeverage`

To set the `UniverseSettings` , update the preceding properties in the `Initialize` method before you add the "Universe Selection model" These settings are globals, so they apply to all universes you create.

```py
# Request second resolution data. This will be slow!
self.UniverseSettings.Resolution = Resolution.Second
self.AddUniverseSelection(VolatilityETFUniverse())
```

Configure Securities

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `Initialize` method, call the `SetSecurityInitializer` method and then define the security initializer.

```py
#In Initialize
self.SetSecurityInitializer(self.CustomSecurityInitializer)

def CustomSecurityInitializer(self, security: Security) -> None:
    # Disable trading fees
    security.SetFeeModel(ConstantFeeModel(0, "USD"))
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```py
self.SetSecurityInitializer(lambda security: security.SetFeeModel(ConstantFeeModel(0, "USD")))
```

In some cases, you may want to trade a security in the same time loop that you create the security subscription. To avoid errors, use a security initializer to set the market price of each security to the last known price. The `GetLastKnownPrices` method seeds the security price by gathering the security data over the last 3 days. If there is no data during this period, the security price remains at 0.

```py
seeder = FuncSecuritySeeder(self.GetLastKnownPrices)
self.SetSecurityInitializer(lambda security: seeder.SeedSecurity(security))
```

If you call the `SetSecurityInitializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, create a custom `BrokerageModelSecurityInitializer` .

```py
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite some of the reality models
        security.SetFeeModel(ConstantFeeModel(0, "USD"))
```

To set a seeder function without overwriting the reality models of the brokerage, use the standard `BrokerageModelSecurityInitializer`.

```py
self.SetSecurityInitializer(BrokerageModelSecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))
```

Universe Selection

Manual Universes

Introduction

The `ManualUniverseSelectionModel` selects a static, fixed set of assets. It is similar to adding securities with the traditional `AddSecurity` API methods. If your algorithm has a static universe, you can use automatic indicators instead of manual indicators in your algorithm.

Manual universes can be prone to look-ahead bias . For example, if you select a set of securities that have performed well during the backtest period, you are incorporating information from the future into the backtest and the algorithm may underperform in live mode.

Add Manual Universe Selection

To add a `ManualUniverseSelectionModel` to your algorithm, in the `Initialize` method, call the `AddUniverseSelection` method. The `ManualUniverseSelectionModel` constructor expects a list of `Symbol` objects that represent the universe constituents. To create the `Symbol` objects, call the `Symbol.Create` method.

```
PY
tickers = ["SPY", "QQQ", "IWM"]
symbols = [ Symbol.Create(ticker, SecurityType.Equity, Market.USA) for ticker in tickers]
self.AddUniverseSelection(ManualUniverseSelectionModel(symbols))
```

To move the universe tickers and `Symbol` objects outside of the algorithm class, create a universe selection model that inherits the `ManualUniverseSelectionModel` class.

```
PY
# In Initialize
self.AddUniverseSelection(IndexUniverseSelectionModel())

# Outside of the algorithm class
class IndexUniverseSelectionModel(ManualUniverseSelectionModel):
    def __init__(self):
        tickers = ["SPY", "QQQ", "IWM"]
        symbols = [Symbol.Create(ticker, SecurityType.Equity, Market.USA) for ticker in tickers]
        super().__init__(symbols)
```

To view the implementation of this model, see the LEAN GitHub repository .

Universe Selection

Fundamental Universes

Introduction

A `FundamentalUniverseSelectionModel` selects a universe of US Equities based on `CoarseFundamental` and, sometimes, `FineFundamental` data. If the model uses `CoarseFundamental` data, it relies on the US Equity Coarse Universe dataset. If the Universe Selection model uses `FineFundamental` data, it relies on the US Fundamental dataset.

These types of universes operate on daily schedule. In backtests, they select assets at midnight. In live trading, the selection timing depends on the data feed you use.

If you use a fundamental Universe Selection model, the only way to unsubscribe from a security is to return a list from the selection functions that doesn't include the security `Symbol` . The `RemoveSecurity` method doesn't work with these types of Universe Selection models.

Coarse Fundamental Selection

The `CoarseFundamentalUniverseSelectionModel` selects assets based on `CoarseFundamental` data. To use this model, define a coarse selection function. The coarse selection function receives a list of `CoarseFundamental` objects and returns a list of `Symbol` objects. The `Symbol` objects you return from the coarse selection function are the constituents of the universe.

```
PY
def Initialize(self) -> None:
    self.AddUniverseSelection(CoarseFundamentalUniverseSelectionModel(self.SelectCoarse))

def SelectCoarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    selected = [c for c in coarse if c.HasFundamentalData]
    sorted_by_dollar_volume = sorted(selected, key=lambda c: c.DollarVolume, reverse=True)
    return [c.Symbol for c in sorted_by_dollar_volume[:100]] # Return most liquid assets w/ fundamentals
```

To move the coarse selection function outside of the algorithm class, create a universe selection model that inherits the `CoarseFundamentalUniverseSelectionModel` class.

```
PY
# In Initialize
self.AddUniverseSelection(MostLiquidFundamentalUniverseSelectionModel(self.UniverseSettings))

# Outside of the algorithm class
class MostLiquidFundamentalUniverseSelectionModel(CoarseFundamentalUniverseSelectionModel):
    def __init__(self, universe_settings: UniverseSettings) -> None:
        super().__init__(self.SelectCoarse, universe_settings)

    def SelectCoarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        selected = [c for c in coarse if c.HasFundamentalData]
        sorted_by_dollar_volume = sorted(selected, key=lambda c: c.DollarVolume, reverse=True)
        return [c.Symbol for c in sorted_by_dollar_volume[:100]]
```

To return the current universe constituents from the coarse selection function, return `Universe.Unchanged` .

To view the implementation of this model, see the LEAN GitHub repository .

Fine Fundamental Selection

The `FineFundamentalUniverseSelectionModel` selects assets based on `CoarseFundamental` and `FineFundamental` data. This is the only model that provides corporate fundamental data to your algorithm. To use this model, define a coarse selection function and a fine selection function. The coarse selection function receives a list of `CoarseFundamental` objects and returns a list of `Symbol` objects. To filter the `CoarseFundamental` down to the securities that have fundamental data, add a `HasFundamentalData` filter to the coarse selection function. The fine selection function receives a subset of `FineFundamental` objects generated from coarse selection results and returns a list of `Symbol` objects. The `Symbol` objects you return from the fine selection function are the constituents of the universe.

```
PY

def Initialize(self) -> None:
    self.AddUniverseSelection(FineFundamentalUniverseSelectionModel(self.SelectCoarse, self.SelectFine))

def SelectCoarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
    selected = [c for c in coarse if c.HasFundamentalData]
    sorted_by_dollar_volume = sorted(selected, key=lambda c: c.DollarVolume, reverse=True)
    return [c.Symbol for c in sorted_by_dollar_volume[:100]] # Return most liquid assets w/ fundamentals

def SelectFine(self, fine: List[FineFundamental]) -> List[Symbol]:
    sorted_by_pe_ratio = sorted(fine, key=lambda x: x.ValuationRatios.PERatio, reverse=False)
    return [c.Symbol for c in sorted_by_pe_ratio[:10]] # Return assets with lowest P/E ratios
```

To move the selection functions outside of the algorithm class, create a universe selection model that inherits the `FineFundamentalUniverseSelectionModel` class.

```
PY

# In Initialize
self.AddUniverseSelection(LowPERatioUniverseSelectionModel(self.UniverseSettings))

# Outside of the algorithm class
class LowPERatioUniverseSelectionModel(FineFundamentalUniverseSelectionModel):
    def __init__(self, universe_settings: UniverseSettings = None) -> None:
        super().__init__(self.SelectCoarse, self.SelectFine, universe_settings)

    def SelectCoarse(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        selected = [c for c in coarse if c.HasFundamentalData]
        sorted_by_dollar_volume = sorted(selected, key=lambda c: c.DollarVolume, reverse=True)
        return [c.Symbol for c in sorted_by_dollar_volume[:100]]

    def SelectFine(self, fine: List[FineFundamental]) -> List[Symbol]:
        sorted_by_pe_ratio = sorted(fine, key=lambda x: x.ValuationRatios.PERatio, reverse=False)
        return [c.Symbol for c in sorted_by_pe_ratio[:10]]
```

To return the current universe constituents from the coarse or fine selection function, return `Universe.Unchanged` .

If you add a `FineFundamentalUniverseSelectionModel` to your algorithm, you can access fundamental data in the fine selection function or from the `Equity` object. To access fundamental data from the `Equity` object, use the `Equity.Fundamentals` property.

To view the implementation of this model, see the LEAN GitHub repository .

EMA Cross Selection

The `EmaCrossUniverseSelectionModel` applies two exponential moving average (EMA) indicators to the price history

of assets and then selects the assets that have their fast EMA furthest above their slow EMA on a percentage basis.

```
def Initialize(self) -> None:
    self.AddUniverseSelection(EmaCrossUniverseSelectionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fastPeriod`	`int`	Fast EMA period	100
`slowPeriod`	`int`	Slow EMA period	300
`universeCount`	`int`	Maximum number of members of this universe selection	500
`universeSettings`	`UniverseSettings`	The settings used when adding symbols to the algorithm	`None`

If you don't provide a `universeSettings` argument, the `algorithm.UniverseSettings` are used by default.

To view the implementation of this model, see the LEAN GitHub repository .

Universe Selection

ETF Constituents Universes

Introduction

The `ETFConstituentsUniverseSelectionModel` selects a daily universe of US Equities based on the constituents of an ETF. These Universe Selection models rely on the US ETF Constituents dataset.

Add ETF Constituents Universe Selection

To add an `ETFConstituentsUniverseSelectionModel` to your algorithm, in the `Initialize` method, call the `AddUniverseSelection` method. The `ETFConstituentsUniverseSelectionModel` constructor expects an ETF `Symbol` .

```
self.AddUniverseSelection(ETFConstituentsUniverseSelectionModel(etfSymbol))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`etfSymbol`	`Symbol`	`Symbol` of the ETF to get constituents for	
`universeSettings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	`None`
`universeFilterFunc`	`Callable[[List[ETFConstituentData]], List[Symbol]]`	Function to filter ETF constituents. If you don't provide an argument, the model selects all of the ETF constituents by default.	`None`

If you provide a `universeFilterFunc` argument, you can use the following attributes of the `ETFConstituentData` objects to select your universe:

The following example shows how to select the 10 Equities with the largest weight in the SPY ETF:

```
def Initialize(self) -> None:
    symbol = Symbol.Create("SPY", SecurityType.Equity, Market.USA)
    universe = ETFConstituentsUniverseSelectionModel(symbol, self.UniverseSettings,
self.ETFConstituentsFilter)
    self.AddUniverseSelection(universe)

def ETFConstituentsFilter(self, constituents: List[ETFConstituentData]) -> List[Symbol]:
    selected = sorted([c for c in constituents if c.Weight],
        key=lambda c: c.Weight, reverse=True)[:10]
    return [c.Symbol for c in selected]
```

To move the ETF `Symbol` and the selection function outside of the algorithm class, create a universe selection model that inherits the `ETFConstituentsUniverseSelectionModel` class.

```
# In Initialize
self.AddUniverseSelection(LargestWeightSPYETFUniverseSelectionModel(self.UniverseSettings))

# Outside of the algorithm class
class LargestWeightSPYETFUniverseSelectionModel(ETFConstituentsUniverseSelectionModel):
    def __init__(self, universe_settings: UniverseSettings = None) -> None:
        symbol = Symbol.Create("SPY", SecurityType.Equity, Market.USA)
        super().__init__(symbol, universe_settings, self.ETFConstituentsFilter)

    def ETFConstituentsFilter(self, constituents: List[ETFConstituentData]) -> List[Symbol]:
        selected = sorted([c for c in constituents if c.Weight],
            key=lambda c: c.Weight, reverse=True)[:10]
        return [c.Symbol for c in selected]
```

To return the current universe constituents from the selection function, return `Universe.Unchanged` .

To view the implementation of this model, see the LEAN GitHub repository .

Universe Selection

Scheduled Universes

Introduction

A Scheduled Universe Selection model selects assets at fixed, regular intervals. In live trading, you can use this type of model to fetch tickers from Dropbox or to perform periodic historical analysis and select some assets.

Scheduled Universe Selection

The `ScheduledUniverseSelectionModel` selects assets on the schedule you provide. To use this model, provide a `DateRule` , `TimeRule` , and a selector function. The `DateRule` and `TimeRule` define the selection schedule. The selector function receives a `datetime` object and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the constituents of the universe.

```
self.AddUniverseSelection(ScheduledUniverseSelectionModel(dateRule, timeRule, selector))
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`dateRule`	`IDateRule`	Date rule defines what days the universe selection function will be invoked	
`timeRule`	`ITimeRule`	Time rule defines what times on each day selected by date rule the universe selection function will be invoked	
`selector`	`Callable[[datetime], List[Symbol]]`	Selector function accepting the date time firing time and returning the universe selected symbols	
`settings`	`UniverseSettings`	Universe settings for subscriptions added via this universe, null will default to algorithm's universe settings	`None`

If you don't provide a `settings` argument, the `algorithm.UniverseSettings` is used by default.

The model assumes the `timeRule` argument is in Coordinated Universal Time (UTC). To use a different timezone, pass a `timeZone` argument of type `DateTimeZone` before the `dateRule` argument.

To return the current universe constituents from the selector function, return `Universe.Unchanged` .

```py
# Selection will run on mon/tues/thurs at 00:00/06:00/12:00/18:00
self.AddUniverseSelection(ScheduledUniverseSelectionModel(
    self.DateRules.Every(DayOfWeek.Monday, DayOfWeek.Tuesday, DayOfWeek.Thursday),
    self.TimeRules.Every(timedelta(hours = 6)),
    self.SelectSymbols # selection function in algorithm.
))

# Create selection function which returns symbol objects.
def SelectSymbols(self, dateTime: datetime) -> List[Symbol]:
    tickers = ['SPY', 'AAPL', 'IBM']
    return [Symbol.Create(ticker, SecurityType.Equity, Market.USA)
        for ticker in tickers]
```

To view the implementation of this model, see the LEAN GitHub repository .

Date Rules

The following table describes the supported `DateRules` :

Member	Description
`self.DateRules.SetDefaultTimeZone(time_zone: DateTimeZone)`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`self.DateRules.On(year: int, month: int, day: int)`	Trigger an event on a specific date.
`self. DateRules.EveryDay()`	Trigger an event every day.
`self.DateRules.EveryDay(symbol: Symbol)`	Trigger an event every day a specific symbol is trading.
`self.DateRules.Every(days: List[DayOfWeek])`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`self.DateRules.MonthStart(daysOffset: int = 0)`	Trigger an event on the first day of each month plus an offset.
`self.DateRules.MonthStart(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`self.DateRules.MonthEnd(daysOffset: int = 0)`	Trigger an event on the last day of each month minus an offset.
`self.DateRules.MonthEnd(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`self.DateRules.WeekStart(daysOffset: int = 0)`	Trigger an event on the first day of each week plus an offset.
`self.DateRules.WeekStart(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`self.DateRules.WeekEnd(daysOffset: int = 0)`	Trigger an event on the last day of each week minus an offset.
`self.DateRules.WeekEnd(symbol: Symbol, daysOffset: int = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`self. DateRules.Today`	Trigger an event once today.
`self. DateRules.Tomorrow`	Trigger an event once tomorrow.

Time Rules

The following table describes the supported `TimeRules` :

Member	Description
`self.TimeRules.SetDefaultTimeZone(time_zone: DateTimeZone)`	Sets the time zone for the `TimeRules` object used in all methods in this table, except when a different time zone is given. The default time zone is the algorithm time zone .
`self.TimeRules.AfterMarketOpen(symbol: Symbol, minutesAfterOpen: float = 0, extendedMarketOpen: bool = False)`	Trigger an event a few minutes after market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.TimeRules.BeforeMarketClose(symbol: Symbol, minutesBeforeClose: float = 0, extendedMarketOpen: bool = False)`	Trigger an event a few minutes before market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`self.TimeRules.Every(interval: timedelta)`	Trigger an event every period interval starting at midnight.
`self. TimeRules.Now`	Trigger an event at the current time of day.
`self. TimeRules.Midnight`	Trigger an event at midnight.
`self. TimeRules.Noon`	Trigger an event at noon.
`self.TimeRules.At(hour: int, minute: int, second: int = 0)`	Trigger an event at a specific time of day (e.g. 13:10).
`self.TimeRules.At(hour: int, minute: int, second: int, time_zone: DateTimeZone)`	Trigger an event at a specific time of day in the given time zone (e.g. 13:10 UTC).

Examples

PY

```
# Select the universe on a specific date at a specific time
self.AddUniverseSelection(ScheduledUniverseSelectionModel(
    self.DateRules.On(2013, 10, 7),
    self.TimeRules.At(13, 0),
    self.select_symbols))

# Select the universe 10 minutes after SPY starts trading each day
self.AddUniverseSelection(ScheduledUniverseSelectionModel(
    self.DateRules.EveryDay("SPY"),
    self.TimeRules.AfterMarketOpen("SPY", 10),
    self.select_symbols))

# Select the universe 10 minutes before SPY stops trading each day
self.AddUniverseSelection(ScheduledUniverseSelectionModel(
    self.DateRules.EveryDay("SPY"),
    self.TimeRules.BeforeMarketClose("SPY", 10),
    self.select_symbols))

# Select the universe on Monday and Friday at noon
self.AddUniverseSelection(ScheduledUniverseSelectionModel(
    self.DateRules.Every(DayOfWeek.Monday, DayOfWeek.Friday),
    self.TimeRules.At(12, 0),
    self.select_symbols))

# Select the universe now
self.AddUniverseSelection(ScheduledUniverseSelectionModel(
    self.DateRules.Today,
```

```
        self.TimeRules.Now,
        self.select_symbols))

    # Select the universe tomorrow at midnight
    self.AddUniverseSelection(ScheduledUniverseSelectionModel(
        self.DateRules.Tomorrow,
        self.TimeRules.Midnight,
        self.select_symbols))

    # Select the universe today at noon
    self.AddUniverseSelection(ScheduledUniverseSelectionModel(
        self.DateRules.Today,
        self.TimeRules.Noon,
        self.select_symbols))

    # Select the universe every 10 minutes on everyday
    self.AddUniverseSelection(ScheduledUniverseSelectionModel(
        self.DateRules.EveryDay(),
        self.TimeRules.Every(timedelta(minutes=10)),
        self.select_symbols))

    # Select the universe at the market open on the first day of the month the SPY starts trading
    self.AddUniverseSelection(ScheduledUniverseSelectionModel(
        self.DateRules.MonthStart("SPY"),
        self.TimeRules.AfterMarketOpen("SPY"),
        self.select_symbols))

    # Select the universe at the market close on the last day of the month the SPY trades
    self.AddUniverseSelection(ScheduledUniverseSelectionModel(
        self.DateRules.MonthEnd("SPY"),
        self.TimeRules.BeforeMarketClose("SPY"),
        self.select_symbols))

    # Select the universe 5 minutes after SPY starts trading each week
    self.AddUniverseSelection(ScheduledUniverseSelectionModel(
        self.DateRules.WeekStart("SPY"),
        self.TimeRules.AfterMarketOpen("SPY", 5),
        self.select_symbols))

    # Select the universe 5 minutes before the SPY stops trading each week
    self.AddUniverseSelection(ScheduledUniverseSelectionModel(
        self.DateRules.WeekEnd("SPY"),
        self.TimeRules.BeforeMarketClose("SPY", 5),
        self.select_symbols))

    # Define a selection function that returns Symbol objects
    def select_symbols(self, date_time: datetime) -> List[Symbol]:
        tickers = ['SPY', 'AAPL', 'IBM']
        return [Symbol.Create(ticker, SecurityType.Equity, Market.USA)
            for ticker in tickers]
```

Demonstration Algorithms
ScheduledUniverseSelectionModelRegressionAlgorithm.py Python

Universe Selection

Futures Universes

Introduction

A Future Universe Selection model selects contracts for a set of Futures.

Future Universe Selection

The `FutureUniverseSelectionModel` selects all the contracts for a set of Futures you specify. To use this model, provide a `refreshInterval` and a selector function. The `refreshInterval` defines how frequently LEAN calls the selector function. The selector function receives a `datetime` object that represents the current Coordinated Universal Time (UTC) and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the Futures of the universe.

```
PY
from Selection.FutureUniverseSelectionModel import FutureUniverseSelectionModel

self.AddUniverseSelection(FutureUniverseSelectionModel(refreshInterval, futureChainSymbolSelector))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`refreshInterval`	`timedelta`	Time interval between universe refreshes	
`futureChainSymbolSelector`	`Callable[[datetime], List[Symbol]]`	A function that selects the Future symbols for a given Coordinated Universal Time (UTC). To view the supported assets in the US Futures dataset, see Supported Assets .	
`universeSettings`	`UniverseSettings`	Universe settings define attributes of created subscriptions, such as their resolution and the minimum time in universe before they can be removed	`None`

If you don't provide a `universeSettings` argument, the `algorithm.UniverseSettings` is used by default.

```py
from Selection.FutureUniverseSelectionModel import FutureUniverseSelectionModel

def Initialize(self) -> None:
    universe = FutureUniverseSelectionModel(timedelta(days=1), self.select_future_chain_symbols)
    self.SetUniverseSelection(universe)

def select_future_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
    return [ Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME),
             Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX) ]
```

This model uses the default Future contract filter, which doesn't select any Futures contracts. To use a different filter, subclass the `FutureUniverseSelectionModel` and define a `Filter` method. The `Filter` method accepts and returns a `FutureFilterUniverse` object to select the Futures contracts. The following table describes the filter methods of the `FutureFilterUniverse` class:

Method	Description
`StandardsOnly()`	Selects standard contracts
`IncludeWeeklys()`	Selects non-standard weekly contracts
`WeeklysOnly()`	Selects weekly contracts
`FrontMonth()`	Selects the front month contract
`BackMonths()`	Selects the non-front month contracts
`BackMonth()`	Selects the back month contracts
`Expiration(minExpiry: timedelta, maxExpiry: timedelta)`	Selects contracts that expire within a range of dates relative to the current day
`Expiration(minExpiryDays: int, maxExpiryDays: int)`	Selects contracts that expire within a range of dates relative to the current day
`Contracts(contracts: List[Symbol])`	Selects a list of contracts
`Contracts(contractSelector: Callable[[List[Symbol]], List[Symbol]])`	Selects contracts that a selector function selects
`OnlyApplyFilterAtMarketOpen()`	Instructs the engine to only filter contracts on the first time step of each market day

Depending on how you define the contract filter, LEAN may call it once a day or at every time step.

```py
from Selection.FutureUniverseSelectionModel import FutureUniverseSelectionModel

# In Initialize
self.AddUniverseSelection(FrontMonthFutureUniverseSelectionModel())

# Outside of the algorithm class
class FrontMonthFutureUniverseSelectionModel(FutureUniverseSelectionModel):
    def __init__(self) -> None:
        super().__init__(timedelta(1), self.select_future_chain_symbols)

    def select_future_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
        return [
            Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME),
            Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX)
        ]

    def Filter(self, filter: FutureFilterUniverse) -> FutureFilterUniverse:
        return filter.FrontMonth().OnlyApplyFilterAtMarketOpen()
```

Some of the preceding filter methods only set an internal enumeration in the `FutureFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `FutureFilterUniverse` .

The `AddUniverseSelection` method doesn't return a `Future` object like the AddFuture method. The `Future` object contains `Symbol` and `Mapped` properties, which reference the continuous contract and the currently selected contract in the continuous contract series, respectively. To get the `Future` object, define the `OnSecuritiesChanged` method in your algorithm class or framework models and check the result of the `IsCanonical` method.

```py
def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
    for security in changes.AddedSecurities:
        if security.Symbol.IsCanonical():
            self.future = security
```

To view the implementation of this model, see the LEAN GitHub repository .

Open Interest Future Universe Selection

The `OpenInterestFutureUniverseSelectionModel` is an extension of the `FutureUniverseSelectionModel` that selects the contract with the greatest open interest on a daily basis.

```py
self.AddUniverseSelection(OpenInterestFutureUniverseSelectionModel(algorithm, futureChainSymbolSelector));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
algorithm	IAlgorithm	Algorithm	
futureChainSymbolSelector	Callable[[datetime], List[Symbol]]	A function that selects the Future symbols for a given Coordinated Universal Time (UTC). To view the supported assets in the US Futures dataset, see Supported Assets .	
chainContractsLookupLimit	int/NoneType	Limit on how many contracts to query for open interest	6
resultsLimit	int/NoneType	Limit on how many contracts will be part of the universe	1

```py
def Initialize(self):
    symbols = [
        Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME),
        Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX)
    ]
    universe = OpenInterestFutureUniverseSelectionModel(self, lambda utc_time: symbols)
    self.AddUniverseSelection(universe)
```

To move the selection functions outside of the algorithm class, create a universe selection model that inherits the `OpenInterestFutureUniverseSelectionModel` class.

```py
# In Initialize
self.AddUniverseSelection(GoldOpenInterestFutureUniverseSelectionModel(self))

# Outside of the algorithm class
class GoldOpenInterestFutureUniverseSelectionModel(OpenInterestFutureUniverseSelectionModel):
    def __init__(self, algorithm: QCAlgorithm, chainContractsLookupLimit: int = 6, resultsLimit: int = 1):
        super().__init__(algorithm, self.select_future_chain_symbols, chainContractsLookupLimit,
resultsLimit)

    def select_future_chain_symbols(self, utcTime: datetime) -> List[Symbol]:
        return [Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX)]
```

The `AddUniverseSelection` method doesn't return a `Future` object like the AddFuture method. The `Future` object contains `Symbol` and `Mapped` properties, which reference the continuous contract and the currently selected contract in the continuous contract series, respectively. To get the `Future` object, define the `OnSecuritiesChanged` method in your algorithm class or framework models and check the result of the `IsCanonical` method.

```py
def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
    for security in changes.AddedSecurities:
        if security.Symbol.IsCanonical():
            self.future = security
```

To view the implementation of this model, see the LEAN GitHub repository .

Universe Selection

Options Universes

Introduction

An Option Universe Selection model selects contracts for a set of Options.

Options Universe Selection

The `OptionUniverseSelectionModel` selects all the available contracts for the Equity Options, Index Options, and Future Options you specify. To use this model, provide a `refreshInterval` and a selector function. The `refreshInterval` defines how frequently LEAN calls the selector function. The selector function receives a `datetime` object that represents the current Coordinated Universal Time (UTC) and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the Options of the universe.

```
PY
from Selection.OptionUniverseSelectionModel import OptionUniverseSelectionModel

self.AddUniverseSelection(OptionUniverseSelectionModel(refreshInterval, optionChainSymbolSelector))
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`refreshInterval`	`timedelta`	Time interval between universe refreshes	
`optionChainSymbolSelector`	`Callable[[datetime], List[Symbol]]`	A function that selects the Option symbols	
`universeSettings`	`UniverseSettings`	Universe settings define attributes of created subscriptions, such as their resolution and the minimum time in universe before they can be removed	`None`

If you don't provide a `universeSettings` argument, the `algorithm.UniverseSettings` is used by default.

```py
from Selection.OptionUniverseSelectionModel import OptionUniverseSelectionModel

def Initialize(self) -> None:
    universe = OptionUniverseSelectionModel(timedelta(days=1), self.select_option_chain_symbols)
    self.SetUniverseSelection(universe)

def select_option_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
    # Equity Options example:
    #tickers = ["SPY", "QQQ", "TLT"]
    #return [Symbol.Create(ticker, SecurityType.Option, Market.USA) for ticker in tickers]

    # Index Options example:
    #tickers = ["VIX", "SPX"]
    #return [Symbol.Create(ticker, SecurityType.IndexOption, Market.USA) for ticker in tickers]

    # Future Options example:
    future_symbol = Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME)
    future_contract_symbols = self.FutureChainProvider.GetFutureContractList(future_symbol, self.Time)
    return [Symbol.CreateCanonicalOption(symbol) for symbol in future_contract_symbols]
```

This model uses the default Option filter, which selects the Option contracts with the following characteristics at every time step:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 31 days

To use a different filter for the contracts, subclass the `OptionUniverseSelectionModel` and define a `Filter` method. The `Filter` method accepts and returns an `OptionFilterUniverse` object to select the Option contracts. The following table describes the methods of the `OptionFilterUniverse` class:

Method	Description
`Strikes(minStrike: int, maxStrike: int)`	Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price
`CallsOnly()`	Selects call contracts
`PutsOnly()`	Selects put contracts
`StandardsOnly()`	Selects standard contracts
`IncludeWeeklys()`	Selects non-standard weeklys contracts
`WeeklysOnly()`	Selects weekly contracts
`FrontMonth()`	Selects the front month contract
`BackMonths()`	Selects the non-front month contracts
`BackMonth()`	Selects the back month contracts
`Expiration(minExpiry: timedelta, maxExpiry: timedelta)`	Selects contracts that expire within a range of dates relative to the current day
`Expiration(minExpiryDays: int, maxExpiryDays: int)`	Selects contracts that expire within a range of dates relative to the current day
`Contracts(contracts: List[Symbol])`	Selects a list of contracts
`Contracts(contractSelector: Callable[[List[Symbol]], List[Symbol]])`	Selects contracts that a selector function selects
`OnlyApplyFilterAtMarketOpen()`	Instructs the engine to only filter contracts on the first time step of each market day

Depending on how you define the contract filter, LEAN may call it once a day or at every time step.

To move the selection functions outside of the algorithm class, create a universe selection model that inherits the `OptionUniverseSelectionModel` class.

```
PY
from Selection.OptionUniverseSelectionModel import OptionUniverseSelectionModel

# In Initialize
self.AddUniverseSelection(EarliestExpiringAtTheMoneyCallOptionUniverseSelectionModel(self))

# Outside of the algorithm class
class EarliestExpiringAtTheMoneyCallOptionUniverseSelectionModel(OptionUniverseSelectionModel):
    def __init__(self, algorithm):
        self.algo = algorithm
        super().__init__(timedelta(1), self.select_option_chain_symbols)

    def select_option_chain_symbols(self, utc_time: datetime) -> List[Symbol]:
        # Equity Options example:
        #tickers = ["SPY", "QQQ", "TLT"]
        #return [Symbol.Create(ticker, SecurityType.Option, Market.USA) for ticker in tickers]

        # Index Options example:
        #tickers = ["VIX", "SPX"]
        #return [Symbol.Create(ticker, SecurityType.IndexOption, Market.USA) for ticker in tickers]

        # Future Options example:
        future_symbol = Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME)
        future_contract_symbols = self.algo.FutureChainProvider.GetFutureContractList(future_symbol,
self.algo.Time)
        return [Symbol.CreateCanonicalOption(symbol) for symbol in future_contract_symbols]

    def Filter(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
        return option_filter_universe.Strikes(-1, -1).Expiration(0,
7).CallsOnly().OnlyApplyFilterAtMarketOpen()
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

To override the default pricing model of the Options, set a pricing model in a security initializer.

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

To view the implementation of this model, see the LEAN GitHub repository .

Option Chained Universe Selection

An Option chained universe subscribes to Option contracts on the constituents of a US Equity universe .

```
PY
self.AddUniverseOptions(universe, optionFilter)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`universe`	`Universe`	The universe to chain onto the Option Universe Selection model	
`optionFilter`	`Callable[[OptionFilterUniverse], OptionFilterUniverse]`	The Option filter universe to use	

The `optionFilter` function receives and returns an `OptionFilterUniverse` to select the Option contracts. The following table describes the methods of the `OptionFilterUniverse` class:

Method	Description
`Strikes(minStrike: int, maxStrike: int)`	Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price
`CallsOnly()`	Selects call contracts
`PutsOnly()`	Selects put contracts
`StandardsOnly()`	Selects standard contracts
`IncludeWeeklys()`	Selects non-standard weeklys contracts
`WeeklysOnly()`	Selects weekly contracts
`FrontMonth()`	Selects the front month contract
`BackMonths()`	Selects the non-front month contracts
`BackMonth()`	Selects the back month contracts
`Expiration(minExpiry: timedelta, maxExpiry: timedelta)`	Selects contracts that expire within a range of dates relative to the current day
`Expiration(minExpiryDays: int, maxExpiryDays: int)`	Selects contracts that expire within a range of dates relative to the current day
`Contracts(contracts: List[Symbol])`	Selects a list of contracts
`Contracts(contractSelector: Callable[[List[Symbol]], List[Symbol]])`	Selects contracts that a selector function selects
`OnlyApplyFilterAtMarketOpen()`	Instructs the engine to only filter contracts on the first time step of each market day

PY

```
def Initialize(self) -> None:
    universe = self.AddUniverse(self.Universe.DollarVolume.Top(10))
    self.AddUniverseOptions(universe, self.OptionFilterFunction)

def OptionFilterFunction(self, option_filter_universe: OptionFilterUniverse) -> OptionFilterUniverse:
    return option_filter_universe.Strikes(-2, +2).FrontMonth().CallsOnly()
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

To override the default pricing model of the Options, set a pricing model in a security initializer.

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

To view the implementation of this model, see the LEAN GitHub repository .

Algorithm Framework

Alpha

Alpha

Key Concepts

Introduction

The Alpha model predicts market trends and signals the best moments to trade. These signals, or `Insight` objects, contain the `Direction` , `Magnitude` , and `Confidence` of a market prediction and the suggested portfolio `Weight` . You should generate insights on the set of assets provided by the Universe Selection model and only generate them when your predictions change.

Add Models

To add an Alpha model, in the `Initialize` method, call the `AddAlpha` method.

```
self.AddAlpha(EmaCrossAlphaModel())
```

PY

To view all the pre-built Alpha models, see Supported Models .

Multi-Alpha Algorithms

You can add multiple Alpha models to a single algorithm and generate Insight objects with all of them.

```
self.AddAlpha(RsiAlphaModel())
self.AddAlpha(EmaCrossAlphaModel())
```

PY

Each Alpha model has a unique name. The Insight objects they generate are automatically named according to the Alpha model name.

If you add multiple Alpha models, each alpha model receives the current slice in the order that you add the Alphas. The combined stream of Insight objects is passed to the Portfolio Construction model that defines how the Insight collection is combined. If you have a hybrid algorithm, the combined stream of Insight objects is passed to the event handler .

Model Structure

Alpha models should extend the `AlphaModel` class. Extensions of the `AlphaModel` class must implement the `Update` method, which receives a Slice object and returns an array of `Insight` objects. Extensions should also implement the `OnSecuritiesChanged` method to track security changes in the universe.

```py
# Algorithm framework model that produces insights
class MyAlphaModel(AlphaModel):

    def Update(self, algorithm: QCAlgorithm, data: Slice) -> List[Insight]:
        # Updates this Alpha model with the latest data from the algorithm.
        # This is called each time the algorithm receives data for subscribed securities
        # Generate insights on the securities in the universe.
        insights = []
        return insights

    def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        # Security additions and removals are pushed here.
        # This can be used for setting up algorithm state.
        # changes.AddedSecurities
        # changes.RemovedSecurities
        pass
```

Method Parameters

The `algorithm` parameter that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it. To access members of your algorithm object, either use a global variable or pass an algorithm reference to Alpha model constructor. Both of these approaches violate the separation of concerns principle.

The `data` parameter contains the latest data available to the algorithm.

The `changes` parameter contains the universe changes.

Model Names

To ensure your Alpha model is compatible with all Portfolio Construction models , assign a unique name to your Alpha model. Some Portfolio Construction models can combine multiple Alpha models together, so it can be important to distinguish between the Alpha models.

```py
class RsiAlphaModel(AlphaModel):
    Name = "RsiAlphaModel"
```

By default, LEAN uses the string representation of a Guid object to set the Alpha model name. An example default name is "0f8fad5b-d9cb-469f-a165-70867728950e". This default name is different for every backtest you run and every live algorithm you deploy. For consistent behavior, manually set the Alpha model name.

Example

To view a full example of an `AlphaModel` subclass, see the ConstantAlphaModel in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Alpha model. When the Universe Selection model adds and removes assets from the universe, it triggers an `OnSecuritiesChanged` event. In the `OnSecuritiesChanged` event handler, you can initialize the security-specific state or load any history required for your Alpha model.

```
class MyAlphaModel(AlphaModel):
    symbol_data_by_symbol = {}

    def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.AddedSecurities:
            self.symbol_data_by_symbol[security.Symbol] = SymbolData(algorithm, security.Symbol)

        for security in changes.RemovedSecurities:
            if security.Symbol in self.symbol_data_by_symbol:
                symbol_data = self.symbol_data_by_symbol.pop(security.Symbol, None)
                if symbol_data:
                    symbol_data.dispose()

class SymbolData:
    def __init__(self, algorithm, symbol):
        self.algorithm = algorithm
        self.symbol = symbol

        self.indicator = SimpleMovingAverage(20)
        self.consolidator = TradeBarConsolidator(1)
        algorithm.SubscriptionManager.AddConsolidator(symbol, self.consolidator)
        algorithm.RegisterIndicator(symbol, self.indicator, self.consolidator)
        algorithm.WarmUpIndicator(self.symbol, self.indicator)

    def dispose(self):
        self.algorithm.SubscriptionManager.RemoveConsolidator(self.symbol, self.consolidator)
```

Insights

An Insight is a single prediction for an asset. The `Update` method returns an array of Insight objects. You can think of these as actionable trading signals, indicating the asset direction, magnitude, and confidence in the near future. All insights can take a weight parameter to set the desired weighting for the insight. If you change the cash of the algorithm, it will affect the orders, but not necessarily the insights.

The Portfolio Construction model consumes the Insight objects from the Alpha model. It's up to the Portfolio Construction model to define how Insight objects are converted into `PortfolioTarget` objects. In the pre-built Portfolio Construction models, down insights translate to short-biased trades, up insights translate to long-biased trades, and flat insights usually close open positions, but this doesn't have to be the case in custom Portfolio Construction models .

Insight Properties

`Insight` objects have the following properties:

Create Insights

To create an `Insight` , call the `Insight` constructor.

```
# Insight(symbol, period, type, direction, magnitude=None, confidence=None, sourceModel=None, weight=None)
insight = Insight("IBM", timedelta(minutes=20), InsightType.Price, InsightDirection.Up)
```

In the `Insight` constructor, the `period` argument can be a `timedelta` object or a function that receives a `datetime` object and returns the expiry `datetime` . Some of the constructor arguments are optional to create the `Insight` object, but some of the Portfolio Construction models may require these properties. To check which `Insight` properties a Portfolio Construction model requires, see Supported Models .

You can also use the helper method to create Insight objects of the Price type.

```
# Insight.Price(symbol, period, direction, magnitude=None, confidence=None, sourceModel=None, weight=None)
insight = Insight.Price("IBM", timedelta(minutes = 20), InsightDirection.Up)

# Insight.Price(symbol, resolution, barCount, direction, magnitude=None, confidence=None,
sourceModel=None, weight=None)
insight = Insight.Price("IBM", Resolution.Minute, 20, InsightDirection.Up)
```

In the `Price` method, the `period` argument can be a `timedelta` object, a `datetime` object, or a function that receives a `datetime` object and returns the expiry `datetime` .

Group Insights

Sometimes an algorithm's performance relies on multiple insights being traded together, like in pairs trading and options straddles. These types insights should be grouped. Insight groups signal to the Execution model that the insights need to be acted on as a single unit to maximize the alpha created.

To mark insights as a group, call the `Insight.Group` method.

```
return Insight.Group([insight1, insight2,insight3])
```

Cancel Insights

If an Alpha model in your algorithm emits an Insight to enter a position but it determines the trading opportunity has pre-maturely ended, you should cancel the Insight. For example, say you want your algorithm to enter a long position in a security when its Relative Strength Index (RSI) moves below 20 and then liquidate the position when the security's RSI moves above 30. If you emit an Insight that has a duration of 30 days when the RSI moves below 20 but the RSI moves above 30 in 10 days, you should cancel the Insight.

To cancel an Insight, call its `Cancel` / `Expire` method with the algorithm's Coordinated Universal Time (UTC).

```
self.insight.Cancel(algorithm.UtcTime)
```

If you don't have a reference to the Insight you want to cancel, get it from the InsightManager .

When you cancel an insight, it's `CloseTimeUtc` property is set to one second into the past.

Stop Loss Orders Workaround

In some cases, if you add a Risk Management model that uses stop loss logic, the Risk Management model generates `PortfolioTarget` objects with a 0 quantity to make the Execution model liquidate your positions, but then the Portfolio Construction model generates `PortfolioTarget` objects with a non-zero quantity to make the Execution model re-enter the same position. This issue can occur if your Portfolio Construction model rebalances and your Alpha model still has an active insight for the liquidated securities. To avoid this issue, add the stop loss order logic to the Alpha model. When the stop loss is hit, emit a flat insight for the security. Note that this is a workaround, but it violates the separation of concerns principle since the Alpha Model shouldn't react to open positions.

Universe Timing Considerations

If the Alpha model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Alpha

Supported Models

Introduction

This page describes the pre-built Alpha models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Alpha model .

Null Model

The `NullAlphaModel` doesn't emit any insights. It's the default Alpha model.

```
self.AddAlpha(NullAlphaModel())
```

PY

To view the implementation of this model, see the LEAN GitHub repository .

Constant Model

The `ConstantAlphaModel` always returns the same insight for each security.

```
self.AddAlpha(ConstantAlphaModel(type, direction, period))
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`type`	`InsightType`	The type of insight	
`direction`	`InsightDirection`	The direction of the insight	
`period`	`timedelta`	The period over which the insight will come to fruition	
`magnitude`	`float/NoneType`	The predicted change in magnitude as a +/- percentage	`None`
`confidence`	`float/NoneType`	The confidence in the insight	`None`
`weight`	`float/NoneType`	The portfolio weight of the insights	`None`

To view the implementation of this model, see the LEAN GitHub repository .

Historical Returns Model

The `HistoricalReturnsAlphaModel` buys securities that have a positive trailing return and sells securities that have a negative trailing return. It sets the magnitude of the Insight objects to the trailing rate of change.

```
self.AddAlpha(HistoricalReturnsAlphaModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Historical return lookback period	1
`resolution`	`Resolution`	The resolution of historical data	`Resolution.Daily`

This model cancels all the active insights it has emit for a security when the security has a 0% historical return.

To view the implementation of this model, see the LEAN GitHub repository .

EMA Cross Model

The `EmaCrossAlphaModel` uses an exponential moving average (EMA) cross to create insights. When the fast EMA crosses above the slow EMA, it emits up insights. When the fast EMA crosses below the slow EMA, it emits down insights. It sets the duration of Insight objects to be the product of the `resolution` and `fastPeriod` arguments.

```
self.AddAlpha(EmaCrossAlphaModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fastPeriod`	`int`	The fast EMA period	12
`slowPeriod`	`int`	The slow EMA period	26
`resolution`	`Resolution`	The resolution of data sent into the EMA indicators	`Resolution.Daily`

To view the implementation of this model, see the LEAN GitHub repository .

MACD Model

The `MacdAlphaModel` emits insights based on moving average convergence divergence (MACD) crossovers. If the MACD signal line is 1% above the security price, the model emits an up insight. If the MACD signal line is 1% below the security price, the model emits a down insight. If the MACD signal line is within 1% of the security price, the model cancels all the active insights it has emitted for the security.

```
self.AddAlpha(MacdAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fastPeriod`	`int`	The MACD fast period	12
`slowPeriod`	`int`	The MACD slow period	26
`signalPeriod`	`int`	The smoothing period for the MACD signal	9
`movingAverageType`	`MovingAverageType`	The type of moving average to use in the MACD	`MovingAverageType.Exponential`
`resolution`	`Resolution`	The resolution of data sent into the MACD indicator	`Resolution.Daily`

To view the implementation of this model, see the LEAN GitHub repository .

RSI Model

The `RsiAlphaModel` generates insights based on the relative strength index (RSI) indicator values. When the RSI value passes above 70, the model emits a down insight. When the RSI value passes below 30, the model emits an up insight. The model uses the Wilder moving average type and sets the duration of Insight objects to be the product of the `resolution` and `period` arguments.

```
self.AddAlpha(RsiAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`period`	`int`	The RSI indicator period	14
`resolution`	`Resolution`	The resolution of data sent into the RSI indicator	`Resolution.Daily`

To view the implementation of this model, see the LEAN GitHub repository .

Base Pairs Trading Model

The `BasePairsTradingAlphaModel` analyzes every possible pair combination from securities that the Universe Selection model selects. This model calculates a ratio between the two securities by dividing their historical prices over a lookback window. It then calculates the mean of this ratio by taking the 500-period EMA of the quotient. When the ratio

diverges far enough from the mean ratio, this model emits generates alternating long ratio/short ratio insights emitted as a group to capture the reversion of the ratio.

```
self.AddAlpha(BasePairsTradingAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Lookback period of the analysis	1
`resolution`	`Resolution`	Analysis resolution	`Resolution.Daily`
`threshold`	`float`	The percent [0, 100] deviation of the ratio from the mean before emitting an insight	1

To view the implementation of this model, see the LEAN GitHub repository .

Pearson Correlation Pairs Trading Model

The `PearsonCorrelationPairsTradingAlphaModel` ranks every pair combination by its Pearson correlation coefficient and trades the pair with the highest correlation. This model follows the same insight logic as the `BasePairsTradingModel` .

```
self.AddAlpha(PearsonCorrelationPairsTradingAlphaModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Lookback period of the analysis	15
`resolution`	`Resolution`	Analysis resolution	`Resolution.Minute`
`threshold`	`float`	The percent [0, 100] deviation of the ratio from the mean before emitting an insight	1
`minimumCorrelation`	`double float`	The minimum correlation to consider a tradable pair	0.5

To view the implementation of this model, see the LEAN GitHub repository .

Algorithm Framework

Portfolio Construction

Portfolio Construction

Key Concepts

Introduction

The Portfolio Construction model receives `Insight` objects from the Alpha model and creates `PortfolioTarget` objects for the Risk Management model. A `PortfolioTarget` provides the number of units of an asset to hold.

Set Models

To set a Portfolio Construction model, in the `Initialize` method, call the `SetPortfolioConstruction` method.

```
self.SetPortfolioConstruction(EqualWeightingPortfolioConstructionModel())
```

To view all the pre-built Portfolio Construction models, see Supported Models .

Model Structure

Portfolio Construction models should extend the `PortfolioConstructionModel` class or one of the supported models . Extensions of the `PortfolioConstructionModel` class should implement the `CreateTargets` method, which receives an array of `Insight` objects from the Alpha model at every time step and returns an array of `PortfolioTarget` objects. The Portfolio Construction model seeks to answer the question, "how many units should I buy based on the insight predictions I've been presented?".

If you don't override the `CreateTargets` method, the base class implementation calls the model's `IsRebalanceDue` , `DetermineTargetPercent` , and `GetTargetInsights` helper methods. The `GetTargetInsights` method, in turn, calls the model's `ShouldCreateTargetForInsight` method. You can override any of these helper methods. If you don't override the `CreateTargets` method from the `PortfolioConstructionModel` class, your class must at least override the `DetermineTargetPercent` method.

```
 # Portfolio construction scaffolding class; basic method args.
class MyPortfolioConstructionModel(PortfolioConstructionModel):
    # Create list of PortfolioTarget objects from Insights
    def CreateTargets(self, algorithm: QCAlgorithm, insights: List[Insight]) -> List[PortfolioTarget]:
        return super().CreateTargets(algorithm, insights)

    # Determines if the portfolio should rebalance based on the provided rebalancing func
    def IsRebalanceDue(self, insights: List[Insight], algorithmUtc: datetime) -> bool:
        return super().IsRebalanceDue(insights, algorithmUtc)

    # Determines the target percent for each insight
    def DetermineTargetPercent(self, activeInsights: List[Insight]) -> Dict[Insight, float]:
        return {}

    # Gets the target insights to calculate a portfolio target percent for, they will be piped to
DetermineTargetPercent()
    def GetTargetInsights(self) -> List[Insight]:
        return super().GetTargetInsights()

    # Determine if the portfolio construction model should create a target for this insight
    def ShouldCreateTargetForInsight(self, insight: Insight) -> bool:
        return super().ShouldCreateTargetForInsight(insight)

    # Security change details
    def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        super().OnSecuritiesChanged(algorithm, changes)
```

The Portfolio Construction model should remove expired insights from the Insight Manager . The `CreateTargets` definition of the base `PortfolioConstructionModel` class already removes them during each rebalance. Therefore, if you override the `CreateTargets` method and don't call the `CreateTargets` definition of the base class, your new method definition should remove expired insights from the Insight Manager.

The model should also remove all a security's insights from the Insight Manager when the security is removed from the universe . The `OnSecuritiesChanged` definition of the base `PortfolioConstructionModel` class already does this. Therefore, if you override the `OnSecuritiesChanged` method and don't call the `OnSecuritiesChanged` definition of the base class, your new method definition should remove the security's insights from the Insight Manager.

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

You may use the `PortfolioBias` enumeration in the definition of Portfolio Construction model methods. The `PortfolioBias` enumeration has the following members:

To view a full example of a `PortfolioConstructionModel` subclass, see the EqualWeightingPortfolioConstructionModel in the LEAN GitHub repository.

Multi-Alpha Algorithms

If you add multiple Alpha models , each Alpha model receives the current slice in the order that you add the Alphas. The combined stream of Insight objects is passed to the Portfolio Construction model.

Each Portfolio Construction model has a unique method to combine Insight objects. The base `PortfolioConstructionModel` that most PCM's inherit from doesn't combine information from Insight objects with the same `Symbol` - but just gets the most recent active insight. To combine the active insights differently, override the `GetTargetInsights` , and return all active insights. The `DetermineTargetPercent` method implements the combination criteria and determines the target for each `Symbol` .

```
class MultipleAlphaPortfolioConstructionModel(PortfolioConstructionModel):
    def GetTargetInsights(self) -> List[Insight]:
        return list(self.InsightCollection.GetActiveInsights(self.Algorithm.UtcTime))

    def DetermineTargetPercent(self, activeInsights: List[Insight]) -> Dict[Insight, float]:
        return {}
```

Portfolio Targets

The Portfolio Construction model returns `PortfolioTarget` objects, which are passed to the Risk Management model.

To create a `PortfolioTarget` object based on a quantity, pass the `Symbol` and quantity to the `PortfolioTarget` constructor.

```
# Create a new portfolio target for 1200 IBM shares.
target = PortfolioTarget("IBM", 1200)
```

To create a `PortfolioTarget` object based on a portfolio weight, call the `Percent` method. This method is only available for margin accounts.

```
# Calculate target equivalent to 10% of portfolio value
target = PortfolioTarget.Percent(algorithm, "IBM", 0.1)
```

The `CreateTargets` method of your Portfolio Construction model must return an array of `PortfolioTarget` objects.

```
return [ PortfolioTarget("IBM", 1200) ]
```

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `Add` method.

```
self.targets_collection.Add(portfolio_target)
```

To add a list of `PortfolioTarget` objects, call the `AddRange` method.

```
self.targets_collection.AddRange(portfolio_targets)
```

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `Contains` method.

```
target_in_collection = self.targets_collection.Contains(portfolio_target)
```

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `ContainsKey` method.

```
symbol_in_collection = self.targets_collection.ContainsKey(symbol)
```

To get all the Symbol objects, use the `Keys` property.

```
symbols = self.targets_collection.Keys
```

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```
portfolio_target = self.targets_collection[symbol]
```

To iterate through the `PortfolioTargetCollection` , call the `GetEnumerator` method.

```
enumerator = self.targets_collection.GetEnumerator()
```

To get all the `PortfolioTarget` objects, use the `Values` property

```
portfolio_targets = self.targets_collection.Values
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `OrderByMarginImpact` method.

```
for target in self.targets_collection.OrderByMarginImpact(algorithm):
    # Place order
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `Remove` method.

```
remove_successful = self.targets_collection.Remove(symbol)
```

To remove all the `PortfolioTarget` objects, call the `Clear` method.

```
self.targets_collection.Clear()
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `ClearFulfilled` method.

```
self.targets_collection.ClearFulfilled(algorithm)
```

Copy Portfolio Targets

To copy a subset of the `PortfolioTarget` objects in the `PortfolioTargetCollection` to an array, call the `CopyTo` method. The `arrayIndex` argument is the zero-based index in the array at which copying begins.

```
self.targets_collection.CopyTo(array, arrayIndex)
```

Rebalance Frequency

If you use a Portfolio Construction model that is a subclass of the `PortfolioConstructionModel` class, you can set the rebalancing frequency of the model with a function. The rebalancing function receives the Coordinated Universal Time (UTC) of the algorithm and should return the next rebalance UTC time or `None` . If the function returns `None` , the model doesn't rebalance unless the rebalance settings trigger a rebalance. For a full example of a custom rebalance function, see the PortfolioRebalanceOnCustomFuncRegressionAlgorithm .

If you use a Portfolio Construction model with the following characteristics, you can also set the rebalancing frequency of the model with a `timedelta` , `Resolution` , or DateRules :

- The model is a subclass of the `EqualWeightingPortfolioConstructionModel` class.
- The model constructor calls the `EqualWeightingPortfolioConstructionModel` constructor.
- The model doesn't override the `CreateTargets` method.

To check which of the pre-built Portfolio Construction models support this functionality, see Supported Models .

Rebalance Settings

By default, portfolio construction models create `PortfolioTarget` objects to rebalance the portfolio when any of the following events occur:

- The model's rebalance function signals it's time to rebalance
- The Alpha model emits new insights
- The universe changes

To disable rebalances when the Alpha model emits insights or when insights expire, set

`RebalancePortfolioOnInsightChanges` to false.

```
# In Initialize
self.Settings.RebalancePortfolioOnInsightChanges = False
```

To disable rebalances when security changes occur, set `RebalancePortfolioOnSecurityChanges` to false.

```
# In Initialize
self.Settings.RebalancePortfolioOnSecurityChanges = False
```

Portfolio Optimizer Structure

Some portfolio construction models contain an optimizer that accepts the historical returns of each security and returns a list of optimized portfolio weights. Portfolio optimizer models must implement the `IPortfolioOptimizer` interface, which has an `Optimize` method.

```
class MyPortfolioOptimizer:

    def Optimize(self, historicalReturns: pd.DataFrame, expectedReturns: pd.Series = None, covariance:
pd.DataFrame = None) -> pd.Series:
        # Create weights
        return weights
```

The following table describes the arguments the `Optimize` method accepts:

Argument	Data Type	Description	Default Value
`historicalReturns`	`DataFrame`	Matrix of annualized historical returns where each column represents a security and each row returns for the given date/time (size: K x N)	
`expectedReturns`	`Series`	Array of double with the portfolio annualized expected returns (size: K x 1)	`None`
`covariance`	`DataFrame`	Multi-dimensional array of double with the portfolio covariance of annualized returns (size: K x K)	`None`

The method should return a K x 1 array of double objects that represent the portfolio weights.

To view all the pre-built portfolio optimization algorithms, see Supported Optimizers .

To view a full example of an `IPortfolioOptimizer` implementation, see the MaximumSharpeRatioPortfolioOptimizer in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Portfolio Construction model. When the Universe Selection model adds and removes assets from the universe, it triggers an `OnSecuritiesChanged` event. In the `OnSecuritiesChanged` event handler, you can initialize the security-specific state or load any history required for your Portfolio Construction model.

```
PY
class MyPortfolioConstructionModel(PortfolioConstructionModel):
    symbol_data_by_symbol = {}

    def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        super().OnSecuritiesChanged(algorithm, changes)
        for security in changes.AddedSecurities:
            self.symbol_data_by_symbol[security.Symbol] = SymbolData(security.Symbol)

        for security in changes.RemovedSecurities:
            if security.Symbol in self.symbol_data_by_symbol:
                self.symbol_data_by_symbol.pop(security.Symbol, None)

class SymbolData:
    def __init__(self, symbol):
        self.symbol = symbol
        # Store and manage Symbol-specific data
```

Universe Timing Considerations

If the Portfolio Construction model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Portfolio Construction

Supported Models

Introduction

This page describes the pre-built Portfolio Construction models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Portfolio Construction model .

Null Model

The `NullPortfolioConstructionModel` is the default Portfolio Construction model. It doesn't return any `PortfolioTarget` objects. It's useful if you need to analyze an Alpha model in isolation.

```
PY
self.SetPortfolioConstruction(NullPortfolioConstructionModel())
```

To view the implementation of this model, see the LEAN GitHub repository .

Equal Weighting Model

The `EqualWeightingPortfolioConstructionModel` assigns an equal share of the portfolio to the securities with active insights. This weighting scheme is useful for universe rotation based on simple portfolio strategies.

```
PY
self.SetPortfolioConstruction(EqualWeightingPortfolioConstructionModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.Daily`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

Confidence Weighted Model

The `ConfidenceWeightedPortfolioConstructionModel` generates target portfolio weights based on the `Insight.Confidence` for the last Insight of each Symbol. If the Insight has a direction of `InsightDirection.Up` , the model generates long targets. If the Insight has a direction of `InsightDirection.Down` , the model generates short

targets. If the sum of all the last active Insight per Symbol is greater than 1, the model factors down each target percent holdings proportionally so the sum is 1. The model ignores `Insight` objects that have no `Confidence` value.

```
self.SetPortfolioConstruction(ConfidenceWeightedPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

Insight Weighting Model

The `InsightWeightingPortfolioConstructionModel` generates target portfolio weights based on the `Insight.Weight` for the last Insight of each Symbol. If the Insight has a direction of `InsightDirection.Up` , the model generates long targets. If the Insight has a direction of `InsightDirection.Down` , the model generates short targets. If the sum of all the last active Insight per Symbol is greater than 1, the model factors down each target percent holdings proportionally so the sum is 1. The model takes the absolute value of the `Weight` of each `Insight` object and ignores `Insight` objects that have no `Weight` value.

```
self.SetPortfolioConstruction(InsightWeightingPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

Sector Weighting Model

The `SectorWeightingPortfolioConstructionModel` generates target portfolio weights based on the `CompanyReference.IndustryTemplateCode` provided by the US Fundamental dataset . The target percent holdings of each sector is 1/S where S is the number of sectors and the target percent holdings of each security is 1/N where N is the number of securities of each sector. If the insight has a direction of `InsightDirection.Up` , the model generates long targets. If the insight has a direction of `InsightDirection.Down` , the model generates short targets. The model ignores `Insight` objects for Symbols that have no `CompanyReference.IndustryTemplateCode` .

```
self.SetPortfolioConstruction(SectorWeightingPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.Daily`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

Accumulative Insight Model

The `AccumulativeInsightPortfolioConstructionModel` generates target portfolio weights based on all the active insights of a security. For each active Insight of direction `InsightDirection.Up` , it increases the position size by a fixed percent. For each active Insight of direction `InsightDirection.Down` , it decreases the position size by a fixed percent. For each active Insight of direction `InsightDirection.Flat` , it moves the position size towards 0 by a fixed percent.

```
self.SetPortfolioConstruction(AccumulativeInsightPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	Any of the following types: • `timedelta` • `Resolution` • DateRules • `None` • Callable[[datetime], datetime]	Rebalancing parameter. If it's a `timedelta` , `DateRules` or `Resolution` , it's converted into a function. If it's `None` , it's ignored. The function returns the next expected rebalance time for a given algorithm UTC DateTime. The function returns `None` if unknown, in which case the function will be called again in the next loop. If the function returns the current time, the portfolio rebalances.	`None`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`
`percent`	`PortfolioBias`	The percentage amount of the portfolio value to allocate to a single insight	0.03 (3%)

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

Mean Variance Optimization Model

The `MeanVarianceOptimizationPortfolioConstructionModel` seeks to build a portfolio with the least volatility possible and achieve a target return.

```
self.SetPortfolioConstruction(MeanVarianceOptimizationPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`
`lookback`	`int`	Historical return lookback period	1
`period`	`int`	The time interval of history price to calculate the weight	63
`resolution`	`Resolution`	The resolution of the history price	`Resolution.Daily`
`targetReturn`	`float`	The target portfolio return	0.02 (2%)
`optimizer`	`IPortfolioOptimizer`	The portfolio optimization algorithm	`None`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the MinimumVariancePortfolioOptimizer with upper and lower weights that respect the `portfolioBias` .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

Black Litterman Optimization Model

The `BlackLittermanOptimizationPortfolioConstructionModel` receives `Insight` objects from multiple Alphas and combines them into a single portfolio. These multiple sources of Alpha models can be seen as the "investor views" required in the classical model.

```
self.SetPortfolioConstruction(BlackLittermanOptimizationPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`
`lookback`	`int`	Historical return lookback period	1
`period`	`int`	The time interval of history price to calculate the weight	63
`resolution`	`Resolution`	The resolution of the history price	`Resolution.Daily`
`risk_free_rate`	`float`	The risk free rate	0.0
`delta`	`float`	The risk aversion coefficient of the market portfolio	2.5
`tau`	`float`	The model parameter indicating the uncertainty of the CAPM prior	0.05
`optimizer`	`IPortfolioOptimizer`	The portfolio optimization algorithm	`None`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the MinimumVariancePortfolioOptimizer with upper and lower weights that respect the `portfolioBias` .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

Mean Reversion Model

The `MeanReversionPortfolioConstructionModel` implements an on-line portfolio selection technique, named "On-Line Moving Average Reversion" (OLMAR). The basic idea is to represent multi-period mean reversion as "Moving Average Reversion" (MAR), which explicitly predicts next price relatives using moving averages and then forms portfolios with online learning techniques.

```
self.SetPortfolioConstruction(MeanReversionPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`
`reversionThreshold`	`float`	Reversion threshold	1
`windowSize`	`int`	The window size of mean price	20
`resolution`	`Resolution`	The resolution of the history price	`Resolution.Daily`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

- Li, B., Hoi, S. C. (2012). On-line portfolio selection with moving average reversion. arXiv preprint arXiv:1206.4626 .

Risk Parity Model

The `RiskParityPortfolioConstructionModel` seeks to build a portfolio with the equal contribution of risk to the total portfolio risk from all assets.

```
self.SetPortfolioConstruction(RiskParityPortfolioConstructionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalance`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`
`lookback`	`int`	Historical return lookback period	1
`period`	`int`	The time interval of history price to calculate the weight	252
`resolution`	`Resolution`	The resolution of the history price	`Resolution.Daily`
`optimizer`	`IPortfolioOptimizer`	The portfolio optimization algorithm	`None`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the RiskParityPortfolioOptimizer .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

To view the implementation of this model, see the LEAN GitHub repository .

Portfolio Construction

Supported Optimizers

Introduction

This page describes the pre-built Portfolio Optimizer models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Portfolio Optimizer model .

Maximum Sharpe Ratio Optimizer

The `MaximumSharpeRatioPortfolioOptimizer` seeks to maximize the portfolio Sharpe Ratio .

```
optimizer = MaximumSharpeRatioPortfolioOptimizer()
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`minimum_weight`	`float`	The lower bounds on portfolio weights	-1
`maximum_weight`	`float`	The upper bounds on portfolio weights	1
`risk_free_rate`	`float`	The risk free rate	0

To view the implementation of this model, see the LEAN GitHub repository .

Minimum Variance Optimizer

The `MinimumVariancePortfolioOptimizer` seeks to minimize the portfolio variance and achieve a target return.

```
optimizer = MinimumVariancePortfolioOptimizer()
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`minimum_weight`	`float`	The lower bounds on portfolio weights	-1
`maximum_weight`	`float`	The upper bounds on portfolio weights	1
`target_return`	`float`	The target portfolio return	0.02 (2%)

To view the implementation of this model, see the LEAN GitHub repository .

Unconstrained Mean Variance Optimizer

The `UnconstrainedMeanVariancePortfolioOptimizer` seeks to find the optimal risk-adjusted portfolio that lies on the efficient frontier.

```
optimizer = UnconstrainedMeanVariancePortfolioOptimizer(historical_returns)
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`historicalReturns`	`DataFrame`	Matrix of historical returns where each column represents a security and each row returns for the given date/time (size: K x N)	
`expectedReturns`	`Series`	Array of double with the portfolio expected returns (size: K x 1)	`None`
`covariance`	`DataFrame`	Multi-dimensional array of double with the portfolio covariance of returns (size: K x K)	`None`

If you don't provide an argument for `expectedReturns` or `covariance` , it's calculated based on the `historicalReturns` .

To view the implementation of this model, see the LEAN GitHub repository .

Risk Parity Optimizer

The `RiskParityPortfolioOptimizer` seeks to equalize the individual risk contribution to the total portfolio risk from each asset.

```
optimizer = RiskParityPortfolioOptimizer()
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`minimum_weight`	`float`	The lower bounds on portfolio weights	1e-05
`maximum_weight`	`float`	The upper bounds on portfolio weights	`sys.float_info.max`

To view the implementation of this model, see the LEAN GitHub repository .

Algorithm Framework

Risk Management

Risk Management

Key Concepts

Introduction

The Risk Management model seeks to manage risk on the `PortfolioTarget` collection it receives from the Portfolio Construction model before the targets reach the Execution model. There are many creative ways to manage risk. Some examples of risk management include the following:

- *"Trailing Stop Risk Management Model"*
  Create and manage trailing stop-loss orders for open positions.
- *"Option Hedging Risk Management Model"*
  Purchase options to hedge large equity exposures.
- *"Sector Exposure Risk Management Model"*
  Reduce position sizes when overexposed to sectors or individual assets, keeping the portfolio within diversification requirements.
- *"Flash Crash Detection Risk Management Model"*
  Scan for strange market situations that might be precursors to a flash crash and attempt to protect the portfolio when they are detected.

Add Models

To set a Risk Management model, in the `Initialize` method, call the `AddRiskManagement` method.

```
self.AddRiskManagement(NullRiskManagementModel())
```

PY

To view all the pre-built Risk Management models, see Supported Models .

Multi-Model Algorithms

To add multiple Risk Management models, in the `Initialize` method, call the `AddRiskManagement` method multiple times.

```
self.AddRiskManagement(MaximumDrawdownPercentPerSecurity())
self.AddRiskManagement(MaximumSectorExposureRiskManagementModel())
```

PY

If you add multiple Risk Management models, the original collection of `PortfolioTarget` objects from the Portfolio Construction model is passed to the first Risk Management model. The risk-adjusted targets from the first Risk Management model are passed to the second Risk Management model. The process continues sequentially until all of the Risk Management models have had an opportunity to adjust the targets.

Model Structure

Risk Management models should extend the `RiskManagementModel` class. Extensions of the `RiskManagementModel` class must implement the `ManageRisk` method, which receives an array of `PortfolioTarget` objects from the Portfolio Construction model at every time step and should return an array of risk-adjusted `PortfolioTarget` objects. The method should only return the adjusted targets, not all of targets. If the method creates a `PortfolioTarget` object to liquidate a security, cancel the security's insights to avoid re-entering the position.

```
PY
class MyRiskManagementModel(RiskManagementModel):
    # Adjust the portfolio targets and return them. If no changes emit nothing.
    def ManageRisk(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> List[PortfolioTarget]:
        return []

    # Optional: Be notified when securities change
    def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        # Security additions and removals are pushed here.
        # This can be used for setting up algorithm state.
        # changes.AddedSecurities
        # changes.RemovedSecurities
        pass
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

To view a full example of a `RiskManagementModel` subclass, see the MaximumDrawdownPercentPerSecurity in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Risk Management model. When the Universe Selection model adds and removes assets from the universe, it triggers an `OnSecuritiesChanged` event. In the `OnSecuritiesChanged` event handler, you can initialize the security-specific state or load any history required for your Risk Management model.

```
PY
class MyRiskManagementModel(RiskManagementModel):
    symbol_data_by_symbol = {}

    def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        super().OnSecuritiesChanged(algorithm, changes)
        for security in changes.AddedSecurities:
            self.symbol_data_by_symbol[security.Symbol] = SymbolData(security.Symbol)

        for security in changes.RemovedSecurities:
            if security.Symbol in self.symbol_data_by_symbol:
                self.symbol_data_by_symbol.pop(security.Symbol, None)

class SymbolData:
    def __init__(self, symbol):
        self.symbol = symbol
        # Store and manage Symbol-specific data
```

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `Add` method.

```
self.targets_collection.Add(portfolio_target)
```

PY

To add a list of `PortfolioTarget` objects, call the `AddRange` method.

```
self.targets_collection.AddRange(portfolio_targets)
```

PY

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `Contains` method.

```
target_in_collection = self.targets_collection.Contains(portfolio_target)
```

PY

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `ContainsKey` method.

```
symbol_in_collection = self.targets_collection.ContainsKey(symbol)
```

PY

To get all the Symbol objects, use the `Keys` property.

```
symbols = self.targets_collection.Keys
```

PY

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```
portfolio_target = self.targets_collection[symbol]
```

PY

To iterate through the `PortfolioTargetCollection` , call the `GetEnumerator` method.

```
enumerator = self.targets_collection.GetEnumerator()
```

PY

To get all the `PortfolioTarget` objects, use the `Values` property

```
portfolio_targets = self.targets_collection.Values
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `OrderByMarginImpact` method.

```
for target in self.targets_collection.OrderByMarginImpact(algorithm):
    # Place order
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `Remove` method.

```
remove_successful = self.targets_collection.Remove(symbol)
```

To remove all the `PortfolioTarget` objects, call the `Clear` method.

```
self.targets_collection.Clear()
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `ClearFulfilled` method.

```
self.targets_collection.ClearFulfilled(algorithm)
```

Copy Portfolio Targets

To copy a subset of the `PortfolioTarget` objects in the `PortfolioTargetCollection` to an array, call the `CopyTo` method. The `arrayIndex` argument is the zero-based index in the array at which copying begins.

```
self.targets_collection.CopyTo(array, arrayIndex)
```

Universe Timing Considerations

If the Risk Management model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator

- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Risk Management

Supported Models

Introduction

This page describes the pre-built Risk Management models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Risk Management model .

Null Model

The `NullRiskManagementModel` is the default Risk Management model. It doesn't adjust any of the `PortfolioTarget` objects it receives from the Portfolio Construction model.

```
self.AddRiskManagement(NullRiskManagementModel())
```

PY

To view the implementation of this model, see the LEAN GitHub repository .

Maximum Security Drawdown Model

The `MaximumDrawdownPercentPerSecurity` model monitors the unrealized profit percentage of each security in the portfolio. When the percentage drops below a threshold relative to the opening price, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
self.AddRiskManagement(MaximumDrawdownPercentPerSecurity())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumDrawdownPercent`	`float`	The maximum percentage drawdown allowed for any single security holding	0.05 (5%)

To view the implementation of this model, see the LEAN GitHub repository .

Maximum Portfolio Drawdown Model

The `MaximumDrawdownPercentPortfolio` model monitors the portfolio drawdown . The drawdown can be relative to the starting portfolio value or the maximum portfolio value. When the portfolio value drops below a percentage threshold, the model liquidates the portfolio and cancels all insights in the Insight Manager . To liquidate the portfolio, the model

must receive at least 1 `PortfolioTarget` after the drawdown threshold is passed. After the portfolio is liquidated, the model resets. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
self.AddRiskManagement(MaximumDrawdownPercentPortfolio())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumDrawdownPercent`	`float`	Maximum spread accepted comparing to current price in percentage	0.05 (5%)
`isTrailing`	`bool`	If "false", the drawdown is relative to the starting value of the portfolio. If "true", the drawdown is relative the last maximum portfolio value	`False`

To view the implementation of this model, see the LEAN GitHub repository .

Maximum Unrealized Profit Model

The `MaximumUnrealizedProfitPercentPerSecurity` model monitors the unrealized profit of each security in the portfolio. When the unrealized profit exceeds a profit threshold, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
self.AddRiskManagement(MaximumUnrealizedProfitPercentPerSecurity())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumUnrealizedProfitPercent`	`float`	The maximum percentage unrealized profit allowed for any single security holding	0.05 (5%)

To view the implementation of this model, see the LEAN GitHub repository .

Maximum Sector Exposure Model

The `MaximumSectorExposureRiskManagementModel` limits the absolute portfolio exposure in a each industry sector to a predefined maximum percentage. If the absolute portfolio exposure exceeds the maximum percentage, the weight of each Equity in the sector is scaled down so the sector doesn't exceed the maximum percentage. This process requires

assets that are selected by Morningstar fine fundamental data . This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
self.AddRiskManagement(MaximumSectorExposureRiskManagementModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumSectorExposure`	`float`	The maximum exposure for any sector	0.2 (20%)

To view the implementation of this model, see the LEAN GitHub repository .

Trailing Stop Model

The `TrailingStopRiskManagementModel` monitors the drawdown of each security in the portfolio. When the peak-to-trough drawdown of the unrealized profit exceeds a threshold, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
self.AddRiskManagement(TrailingStopRiskManagementModel())
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumDrawdownPercent`	`float`	The maximum percentage drawdown allowed for algorithm portfolio compared with the highest unrealized profit	0.05 (5%)

To view the implementation of this model, see the LEAN GitHub repository .

Algorithm Framework

Execution

Execution

Key Concepts

Introduction

The Execution model receives an array of risk-adjusted `PortfolioTarget` objects from the Risk Management model and places trades in the market to satisfy the targets. The Execution model only receives updates to the portfolio target share counts. It doesn't necessarily receive all of the targets at once.

Set Models

To set an Execution model, in the `Initialize` method, call the `SetExecution` method.

```
self.SetExecution(ImmediateExecutionModel())
```

To view all the pre-built Execution models, see Supported Models .

Model Structure

Execution models should extend the `ExecutionModel` class. Extensions of the `ExecutionModel` must implement the `Execute` method, which receives an array of `PortfolioTarget` objects at every time step and is responsible for reaching the target portfolio as efficiently as possible. The Portfolio Construction model creates the `PortfolioTarget` objects, the Risk Management model may adjust them, and then the Execution model places the orders to fulfill them.

```
# Execution Model scaffolding structure example
class MyExecutionModel(ExecutionModel):

    # Fill the supplied portfolio targets efficiently
    def Execute(self, algorithm: QCAlgorithm, targets: List[PortfolioTarget]) -> None:
        pass

    # Optional: Securities changes event for handling new securities.
    def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        # Security additions and removals are pushed here.
        # This can be used for setting up algorithm state.
        # changes.AddedSecurities
        # changes.RemovedSecurities
        pass
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

The following table describes the properties of the `PortfolioTarget` class that you may access in the Execution model:

Property	Data Type	Description
`Symbol`	`Symbol`	Asset to trade
`Quantity`	`float`	Number of units to hold

To view a full example of an `ExecutionModel` subclass, see the ImmediateExecutionModel in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Execution model. When the Universe Selection model adds and removes assets from the universe, it triggers an `OnSecuritiesChanged` event. In the `OnSecuritiesChanged` event handler, you can initialize the security-specific state or load any history required for your Execution model.

```
PY
class MyExecutionModel(ExecutionModel):
    symbol_data_by_symbol = {}

    def OnSecuritiesChanged(self, algorithm: QCAlgorithm, changes: SecurityChanges) -> None:
        for security in changes.AddedSecurities:
            self.symbol_data_by_symbol[security.Symbol] = SymbolData(security.Symbol)

        for security in changes.RemovedSecurities:
            if security.Symbol in self.symbol_data_by_symbol:
                self.symbol_data_by_symbol.pop(security.Symbol, None)

class SymbolData:
    def __init__(self, symbol):
        self.symbol = symbol
        # Store and manage Symbol-specific data
```

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `Add` method.

```
PY
self.targets_collection.Add(portfolio_target)
```

To add a list of `PortfolioTarget` objects, call the `AddRange` method.

```
PY
self.targets_collection.AddRange(portfolio_targets)
```

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `Contains` method.

```
target_in_collection = self.targets_collection.Contains(portfolio_target)
```

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `ContainsKey` method.

```
symbol_in_collection = self.targets_collection.ContainsKey(symbol)
```

To get all the Symbol objects, use the `Keys` property.

```
symbols = self.targets_collection.Keys
```

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```
portfolio_target = self.targets_collection[symbol]
```

To iterate through the `PortfolioTargetCollection` , call the `GetEnumerator` method.

```
enumerator = self.targets_collection.GetEnumerator()
```

To get all the `PortfolioTarget` objects, use the `Values` property

```
portfolio_targets = self.targets_collection.Values
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `OrderByMarginImpact` method.

```
for target in self.targets_collection.OrderByMarginImpact(algorithm):
    # Place order
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `Remove` method.

```
remove_successful = self.targets_collection.Remove(symbol)
```

To remove all the `PortfolioTarget` objects, call the `Clear` method.

```
self.targets_collection.Clear()
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `ClearFulfilled` method.

```
self.targets_collection.ClearFulfilled(algorithm)
```

Copy Portfolio Targets

To copy a subset of the `PortfolioTarget` objects in the `PortfolioTargetCollection` to an array, call the `CopyTo` method. The `arrayIndex` argument is the zero-based index in the array at which copying begins.

```
self.targets_collection.CopyTo(array, arrayIndex)
```

Universe Timing Considerations

If the Execution model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Execution

Supported Models

Introduction

This page describes the pre-built Execution models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Execution model .

Null Model

The `NullExecutionModel` doesn't place any trades.

```
self.SetExecution(NullExecutionModel())
```

PY

To view the implementation of this model, see the LEAN GitHub repository .

Immediate Model

The `ImmediateExecutionModel` is the default Execution model. It uses market orders to immediately fill portfolio targets. It's similar to placing market orders in line with your algorithm logic.

```
self.SetExecution(ImmediateExecutionModel())
```

PY

To view the implementation of this model, see the LEAN GitHub repository .

Spread Model

The `SpreadExecutionModel` executes trades with market orders if the exchange is open and the bid-ask spread is within a threshold percentage. The model only works if the security subscription provides QuoteBar data. The spread percentage is calculated as

\frac{a - b}{p}

where a is the ask price, b is the bid price, and p is the price.

```
self.SetExecution(SpreadExecutionModel())
```

PY

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`acceptingSpreadPercent`	`float`	Maximum spread accepted comparing to current price in percentage	0.005 (0.5%)

To view the implementation of this model, see the LEAN GitHub repository .

Standard Deviation Model

The `StandardDeviationExecutionModel` seeks to fill orders when the price is more than 2 standard deviations lower than the average price over a trailing period. The intent is to find dips in the market to place trades. In strongly trending markets, this procedure can result in delayed trade placement since it might be a while before the next price spike or dip.

```
self.SetExecution(StandardDeviationExecutionModel())
```

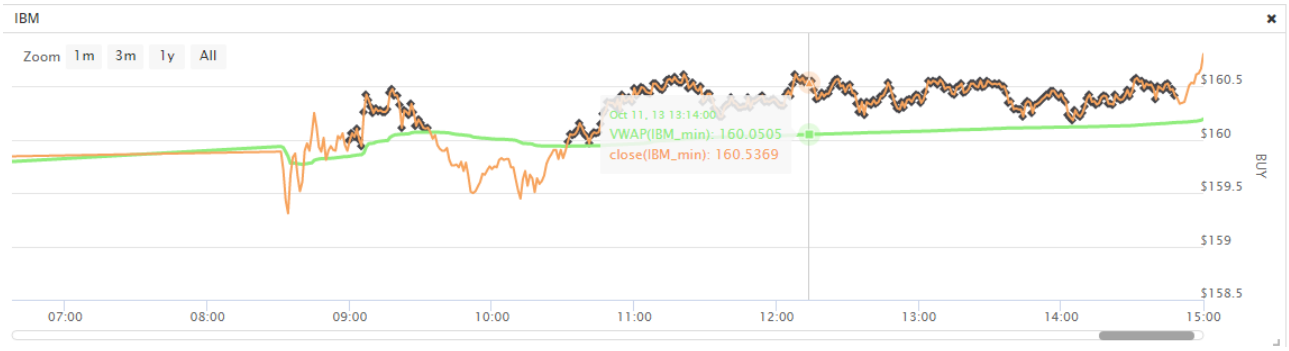
The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`period`	`float`	Period of the standard deviation indicator	60
`deviations`	`int`	The number of deviations away from the mean before submitting an order	2
`resolution`	`Resolution`	The resolution of the STD and SMA indicators	`Resolution.Minute`

To view the implementation of this model, see the LEAN GitHub repository .

VWAP Model

The `VolumeWeightedAveragePriceExecutionModel` works to fill your orders at or better than the volume-weighted average price (VWAP) for the trading day. This is a best-effort algorithm, so no guarantee can be made that it will reach the VWAP.



VWAP Execution Model Fill Placements

The model uses market orders and it only works if the security subscription provides intraday data. It sets a maximum order size of 1% of the current bar's volume, but you can update the maximum order size through the `MaximumOrderQuantityPercentVolume` member.

```
self.SetExecution(VolumeWeightedAveragePriceExecutionModel())
```

To view the implementation of this model, see the LEAN GitHub repository .

Algorithm Framework

Hybrid Algorithms

Introduction

Classic style algorithms can also use Algorithm Framework modules. This allows you to get the best of both styles of algorithm design, combining easily pluggable modules with the superior control of classic format.

Examples of popular use-cases of a hybrid approach are:

- Using framework universe selection models as the assets to select.
- Using portfolio construction models to decide portfolio allocations.
- Using a risk control model for free portfolio risk monitoring.
- Passing data between modules freely without concerns of the module interface.

Universe Selection

You can add one or more Framework Universe Selection Models to your algorithm and it will operate normally. You can also combine it with the `AddUniverse` method of the classic approach. The following example initializes a classic algorithm with framework universe selection models:

```
PY
def Initialize(self):
    self.SetUniverseSelection(ManualUniverseSelectionModel([ Symbol.Create("SPY", SecurityType.Equity,
Market.USA) ]))
    self.AddUniverseSelection(ManualUniverseSelectionModel([ Symbol.Create("AAPL", SecurityType.Equity,
Market.USA) ]))
    self.AddUniverse(self.CoarseSelection)
```

Alpha

You can add one or multiple Alpha models to your classic algorithm and place the orders using `Insight` objects without a Portfolio Construction model. To receive the collection of `Insight` objects in a your classic algorithm, implement the `InsightsGenerated` event handler:

```
PY
def Initialize(self):
    self.AddAlpha(EmaCrossAlphaModel())
    self.InsightsGenerated += self.OnInsightsGenerated

def OnInsightsGenerated(self, algorithm: IAlgorithm, insights_collection: GeneratedInsightsCollection) ->
None:
    insights = insights_collection.Insights
```

Portfolio Construction

You can add a Portfolio Construction model to your classic algorithm and have it place orders without returning `Insight` objects from an Alpha model. To emit insights without an Alpha model, in the `OnData` method, call the `EmitInsights` method.

The following example uses a Portfolio Construction Framework model with `EmitInsights` method in a classic algorithm:

```
PY
def Initialize(self):
    self.SetPortfolioConstruction(EqualWeightingPortfolioConstructionModel())

def OnData(self, slice):
 self.EmitInsights(Insight("GOOG", TimeSpan.FromMinutes(20), InsightType.Price, InsightDirection.Up))
 self.EmitInsights([
  Insight("AAPL", TimeSpan.FromMinutes(20), InsightType.Price, InsightDirection.Up),
  Insight("MSFT", TimeSpan.FromMinutes(20), InsightType.Price, InsightDirection.Up)
 ])
```

Risk Management

Some Risk Management Models don't require a Portfolio Construction model to provide `PortfolioTarget` objects, allowing them to directly monitor the portfolio holdings and liquidate positions when neccessary. To see which pre-built Risk Management models don't need the Portfolio Construction model to provide `PortfolioTarget` objects, see Supported Models .

You can add one or more Risk Management Models to your algorithm and it will operate normally. The following example initializes a classic algorithm with framework risk management models:

```
PY
def Initialize(self):
    self.AddRiskManagement(MaximumDrawdownPercentPerSecurity(0.05))
    self.AddRiskManagement(MaximumUnrealizedProfitPercentPerSecurity(0.1))
```

Execution

Execution models can place orders for your strategy instead of placing them manually. To do so, PortfolioTarget s are routed to the `Execute` method of the Execution Model to place orders.

The following example uses a Framework Execution Model in a classic style algorithm:

```
PY
def Initialize(self):
    self.SetExecution(ImmediateExecutionModel())
```

Universe Timing Considerations

If the Alpha, Portfolio Construction, Risk Management, or Execution model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the

indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Algorithm Framework

Insight Manager

Introduction

The `InsightManager` tracks all of the Insight objects in your algorithm. It's an `InsightCollection` , which stores all of your insights in an internal dictionary that has the security `Symbol` as the key and a list of `Insight` objects as the value. You can access the manager anywhere in your algorithm where you have reference to the algorithm class. If you want to use an `InsightCollection` in your algorithm that's seperate from the `InsightManager` , create a new `InsightCollection` .

Add Insights

To add insights to the `InsightManager` , return a list of `Insight` objects from the Update method of your Alpha model or call the `EmitInsights` method. If you manage an `InsightCollection` that's seperate from the `InsightManager` , there are some methods to add `Insight` objects to it.

To add an insight to an `InsightCollection` , call the `Add` method.

```
self.insight_collection.Add(insight)
```

PY

To add a list of insights, call the `AddRange` method.

```
self.insight_collection.AddRange(insights)
```

PY

Check Membership

To check if an insight exists in the `InsightManager` , call the `Contains` method.

```
if self.algorithm.Insights.Contains(insight):
    pass
```

PY

To check if the `InsightManager` has an insight for a `Symbol` , call the `ContainsKey` method.

```
if self.algorithm.Insights.ContainsKey(symbol):
    pass
```

PY

To check if the `InsightManager` has active insights for a `Symbol` at a specific Coordinated Universal Time (UTC), call the `HasActiveInsights` method.

```
if self.algorithm.Insights.HasActiveInsights(symbol, utc_time):
    pass
```

Get Insights

To get the insights for a `Symbol` , index the `InsightManager` with the `Symbol` .

```
if self.algorithm.Insights.ContainsKey(symbol):
    insights = self.algorithm.Insights[symbol]
```

To get the insights that pass a filter, call the `GetInsights` method.

```
insights = self.algorithm.Insights.GetInsights(lambda insight: insight.Direction == InsightDirection.Up)
```

To iterate through the `InsightManager` , call the `GetEnumerator` method.

```
enumerator = self.algorithm.Insights.GetEnumerator()
```

To get all of the insights that will be active at a certain UTC time, call the `GetActiveInsights` method.

```
active_insights = self.algorithm.Insights.GetActiveInsights(utc_time)
```

Get the Next Expiry Time

To get the next insight expiry time in UTC, call the `GetNextExpiryTime` method.

```
next_expiry = self.algorithm.Insights.GetNextExpiryTime()
```

Remove Insights

Only the Portfolio Construction model should remove insights from the `InsightManager` . It should remove insights when the insights expire and when the corresponding security leaves the universe .

To remove an insight from the `InsightManager` , call the `Remove` method.

```
remove_successful = self.algorithm.Insights.Remove(insight)
```

To remove all the insights for a set of `Symbol` objects, pass a list of `Symbol` objects the `Clear` method.

```
self.algorithm.Insights.Clear(symbols)
```

To remove all the `Insight` objects, call the `Clear` method.

```
PY
self.algorithm.Insights.Clear()
```

To remove all the insights that will be expired at a certain UTC time, call the `RemoveExpiredInsights` method.

```
PY
expired_insights = self.algorithm.Insights.RemoveExpiredInsights(utc_time)
```

Cancel Insights

In some cases, you may want to cancel an Insight. For example, if a Risk Management model in your algorithm liquidates a security, it should also cancel all of the active insights for the security. If you don't cancel the insights, the Portfolio Construction model might create a new PortfolioTarget to re-enter the position.

Another example of a situtation where you would want to cancel an Insight is when an Alpha model in your algorithm determines the trading opportunity has pre-maturely ended. For instance, say you want your algorithm to enter a long position in a security when its Relative Strength Index (RSI) moves below 20 and then liquidate the position when the security's RSI moves above 30. If you emit an Insight that has a duration of 30 days when the RSI moves below 20 but the RSI moves above 30 in 10 days, you should cancel the Insight when the RSI moves above 30.

To cancel insights, call the `Cancel` / `Expire` method with a list of `Insight` objects.

```
PY
algorithm.Insights.Cancel(insights)
```

To cancel all the insights for some securities, call the `Cancel` / `Expire` method with a list of `Symbol` objects.

```
PY
algorithm.Insights.Cancel(symbols)
```

When you cancel an active insight, it's `CloseTimeUtc` property is set to one second into the past.

Copy Insights

To copy a subset of the `Insight` objects in the `InsightManager` to an array, call the `CopyTo` method. The `arrayIndex` argument is the zero-based index in the array at which copying begins.

```
PY
self.algorithm.Insights.CopyTo(array, arrayIndex)
```

Preserve Insights Between Deployments

Follow these steps to use the Object Store to preserve the algorithm state across live deployments:

1. Create an algorithm that defines a storage key and adds insights to the Insight Manager .

```
class ObjectStoreChartingAlgorithm(QCAlgorithm):
    def Initialize(self):
        self.insight_key = f"{self.ProjectId}/insights"
        self.SetUniverseSelection(ManualUniverseSelectionModel([ Symbol.Create("SPY",
SecurityType.Equity, Market.USA) ]))
        self.SetAlpha(ConstantAlphaModel(InsightType.Price, InsightDirection.Up, timedelta(5), 0.025,
None))
```

2. At the top of the algorithm file, add the following imports:

```
from Newtonsoft.Json import JsonConvert
from System.Collections.Generic import List
```

`Insight` objects are a C# objects, so you need the preceding C# libraries to serialize and deserialize them.

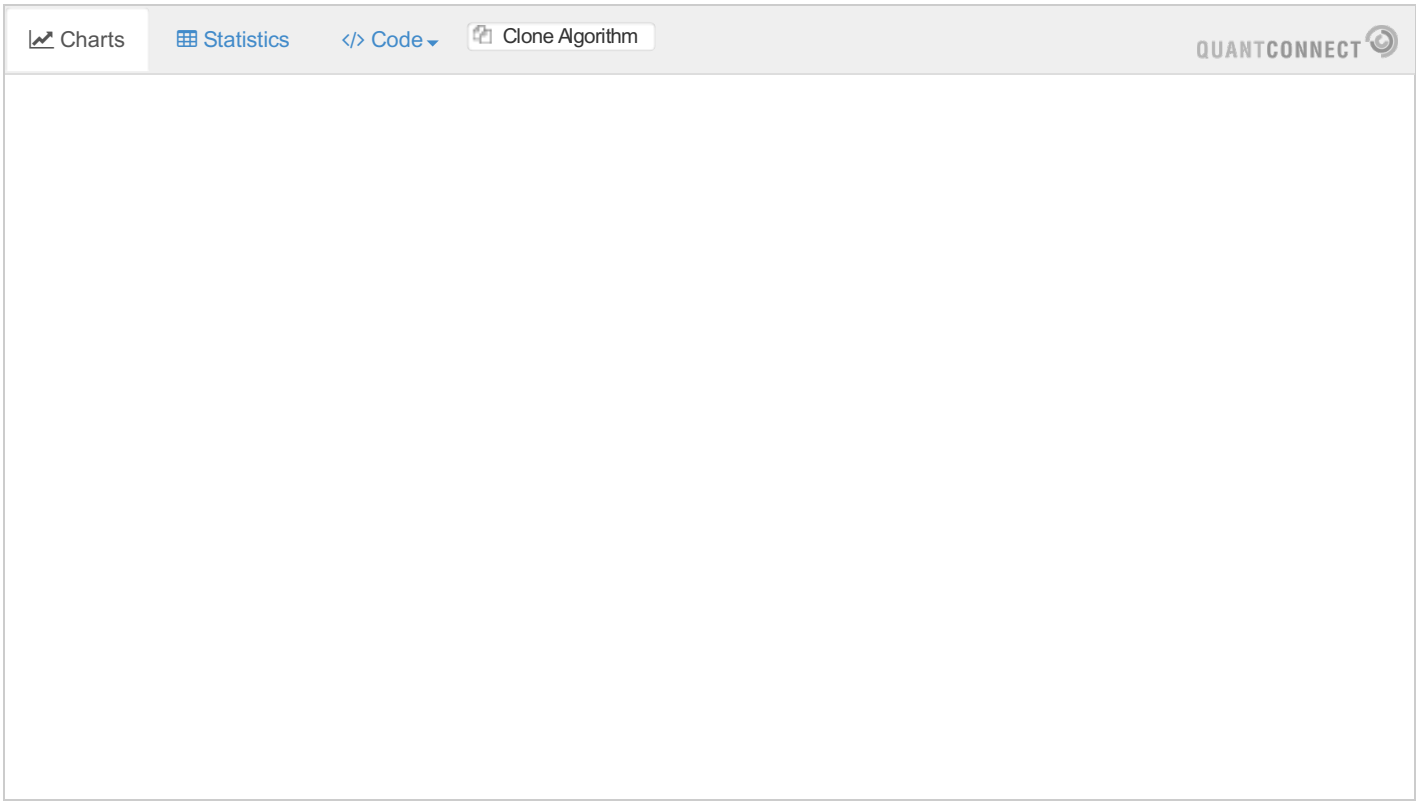
3. In the OnEndOfAlgorithm event handler of the algorithm, get the Insight objects and save them in the Object Store as a JSON object.

```
def OnEndOfAlgorithm(self):
    insights = self.Insights.GetInsights(lambda x: x.IsActive(self.UtcTime))
    content = ','.join([JsonConvert.SerializeObject(x) for x in insights])
    self.ObjectStore.Save(self.insight_key, f'[{content}]')
```

4. At the bottom of the `Initialize` method, read the Insight objects from the Object Store and add them to the Insight Manager .

```
if self.ObjectStore.ContainsKey(self.insight_key):
    insights = self.ObjectStore.ReadJson[List[Insight]](self.insight_key)
    self.Insights.AddRange(insights)
```

The following algorithm provides a full example of preserving the Insight state between deployments:



Properties

The `InsightManager` has the following properties:

Charting

Introduction

We provide a powerful charting API that you can use to build many chart types.

Charts

Charts contain a collection of series, which display data on the chart. To add a chart to an algorithm, create a `Chart` object and then call the `AddChart` method.

```py
chart = Chart("<chartName>")
self.AddChart(chart)
```

The `Chart` constructor expects a name argument. The following chart names are reserved:

- Assets Sales Volume
- Exposure
- Alpha Assets
- Alpha Asset Breakdown

Series

A chart series displays data on the chart. To add a series to a chart, create a `Series` object and then call the `AddSeries` method.

```py
series = Series("<seriesName>")
chart.AddSeries(series)
```

Arguments

There are several other headers for the `Series` constructor.

```
Series(name, type)
Series(name, type, index)
Series(name, type, index, unit)
Series(name, type, unit)
Series(name, type, unit, color)
Series(name, type, unit, color, symbol)
```

The following table describes the constructor arguments:

Argument	Data Type	Description
`name`	`str`	Name of the series
`type`	`SeriesType`	Type of the series
`index`	`int`	Index position on the chart of the series
`unit`	`str`	Unit for the series axis
`color`	`Color`	Color of the series
`symbol`	`ScatterMarkerSymbol`	Symbol for the marker in a scatter plot series

The default `Series` is a line chart with a "$" unit on index 0.

Names

The `Series` constructor expects a name argument. If you add a series to one of the default charts, some series names may be reserved. The following table shows the reserved series name for the default charts:

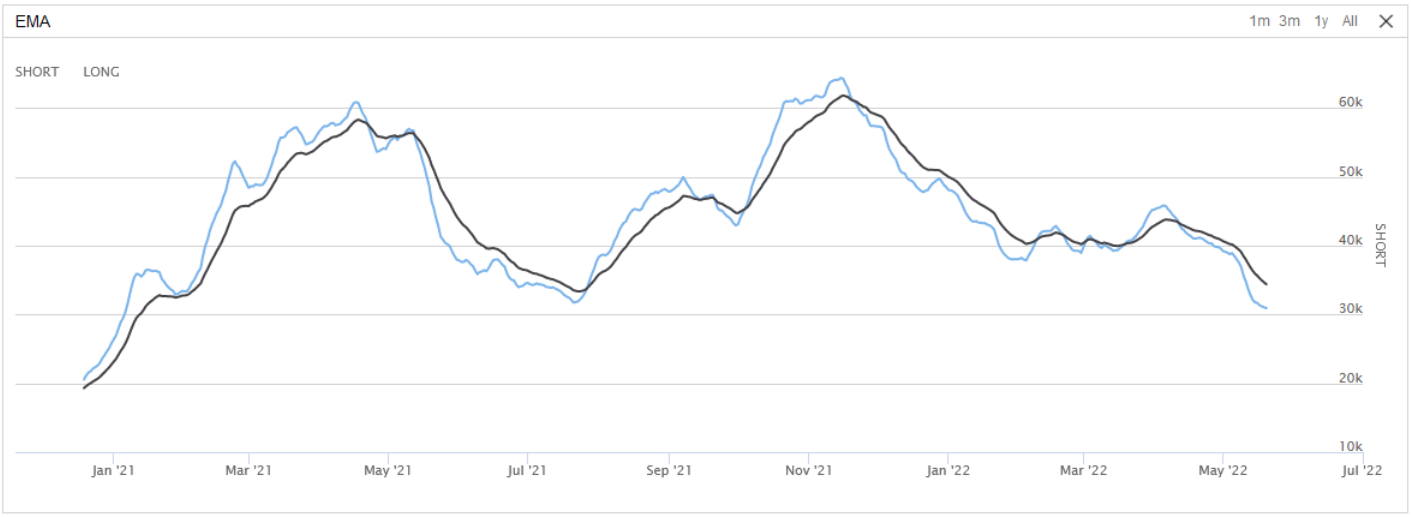
Chart Name	Reserved Series Names
Strategy Equity	Equity, Daily Performance
Capacity	Strategy Capacity
Drawdown	Equity Drawdown
Benchmark	Benchmark

Types

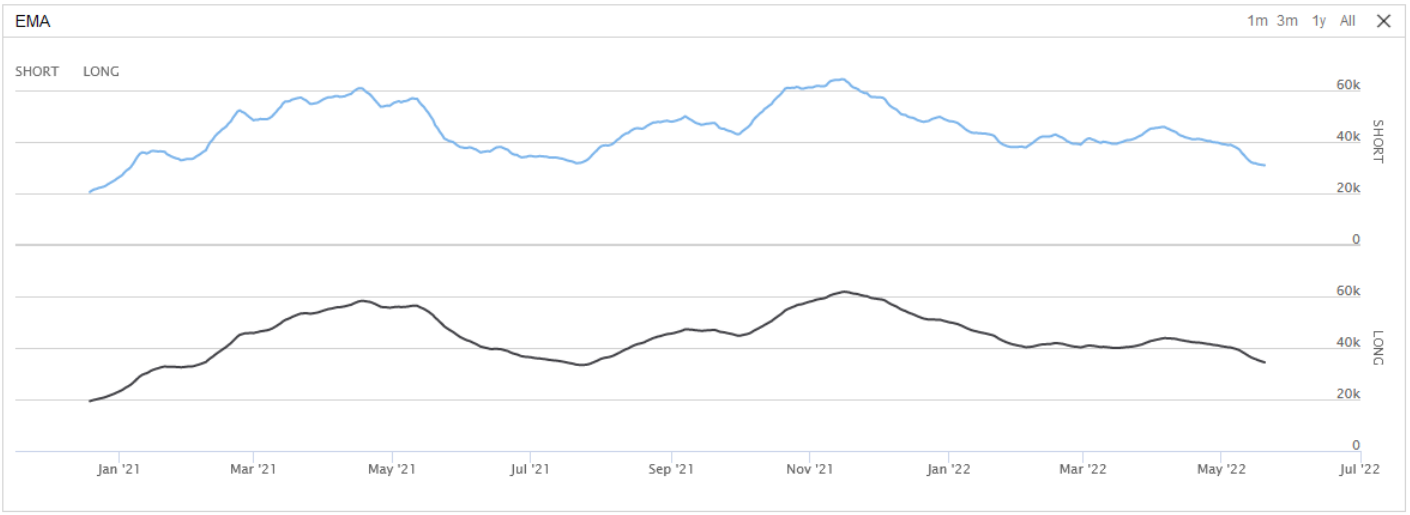
The `SeriesType` enumeration has the following members:

Index

The series index refers to its position in the chart. If all the series are at index 0, they lay on top of each other. If each series has its own index, each series will be separate on the chart. The following image shows an EMA cross chart with both EMA series set to the same index:



The following image shows the same EMA series, but with the short EMA on index 0 and the long EMA on index 1:



Colors

To view the available `Color` options, see the Color Struct Properties in the .NET documentation.

Scatter Marker Symbols

The `ScatterMarkerSymbol` enumeration has the following members:

Plot Data

To add a data point to a chart series, call the `Plot` method. If you haven't already created a chart and series with the names you pass to the `Plot` method, the chart and/or series is automatically created.

```
self.Plot("<chartName>", "<seriesName&gt", value)
```

The `value` argument can be an integer for decimal number. If the chart is a time series, the value is added to the chart using the algorithm time as the x-coordinate.

To plot the current value of indicators, call the `Plot` method. The method accepts up to four indicators.

```py
# In Initialize
symbol = self.AddEquity("SPY")
sma_short = self.SMA(symbol, 10)
sma_long = self.SMA(symbol, 20)

# In OnData
self.Plot("<chartName>", sma_short, sma_long)
```

To plot all of the values of some indicators, in the `Initialize` method, call the `PlotIndicator` method. The method plots each indicator value as the indicator updates. The method accepts up to four indicators.

```py
symbol = self.AddEquity("SPY")
sma_short = self.SMA(symbol, 10)
sma_long = self.SMA(symbol, 20)
self.PlotIndicator("<chartName>", sma_short, sma_long)
```

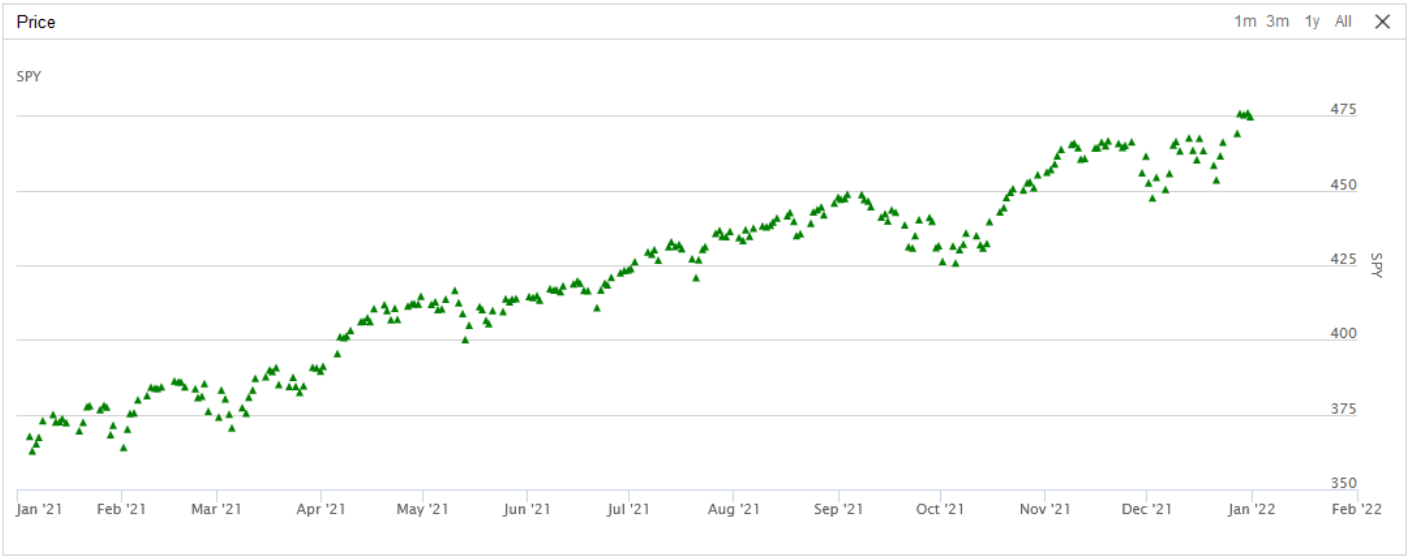
Examples

The following example shows how to plot the daily closing price of SPY with a scatter plot:

```py
class ChartingDemoAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2021, 1, 1)
        self.SetEndDate(2022, 1, 1)
        self.AddEquity("SPY", Resolution.Daily)
        chart = Chart("Price")
        self.AddChart(chart)
        chart.AddSeries(Series("SPY", SeriesType.Scatter, "$", Color.Green, ScatterMarkerSymbol.Triangle))

    def OnEndOfDay(self, symbol: Symbol) -> None:
        self.Plot("Price", "SPY", self.Securities[symbol].Price)
```



To see a full example, run the CustomChartingAlgorithm .

View Charts

The following table describes where you can access your charts, depending on how to deploy your algorithms:

Location	Algorithm Lab Algorithms	CLI Cloud Algorithms	CLI Local Algorithms
Backtest results page	✓	✓	
Live results page	✓	✓	
/backtests/read endpoint	✓	✓	
/live/read endpoint	✓	✓	
ReadBacktest method	✓	✓	
ReadLiveAlgorithm method	✓	✓	
Local **JSON** file in your **<projectName> / backtests / <timestamp>** or **<projectName> / live / <timestamp>** directory		✓	✓

Quotas

Custom charts are limited to 4,000 data points. Intensive charting requires hundreds of megabytes of data, which is too much to stream online or display in a web browser. If you exceed the quota, the following message displays:

Exceeded maximum points per chart, data skipped

You can create up to 10 custom chart series per algorithm. If you exceed the quota, your algorithm stops executing and the following message displays:

Exceeded maximum series count: Each backtest can have up to 10 series in total.

In live trading, charts are sampled every one and ten minutes. If you create 1-minute resolution custom charts, the IDE charting will downgrade the granularity and display the 10-minutes sampling after a certain amount of samples.

Logging

Introduction

Algorithms can record string messages ('log statements') to a file for analysis after a backtest is complete, or as a live algorithm is running. These records can assist in debugging logical flow errors in the project code. Consider adding them in the code block of an `if` statement to signify an error has been caught.

It's good practice to add logging statements to live algorithms so you can understand its behavior and keep records to compare against backtest results. If you don't add logging statements to a live algorithm and the algorithm doesn't trade as you expect, it's difficult to evaluate the underlying problem.

Log Messages

Log statements are added to the log file while your algorithm continues executing. Logging dataset information is not permitted. Use `Log` statements to debug your backtests and live trading algorithms.

If you execute algorithms in QuantConnect Cloud, log length is capped by organization tier . If your organization hits the daily limit, contact us .

If you log the same content multiple times, only the first instance is added to the log file. To bypass this rate-limit, add a timestamp to your log messages.

For live trading, the log files of each cloud project can store up to 100,000 lines for up to one year. If you log more than 100,000 lines or some lines become older than one year, we remove the oldest lines in the files so your project stays within the quota.

To record the algorithm state when the algorithm stops executing, add log statements to the `OnEndOfAlgorithm` event handler.

```
PY
self.Log("My log message")
```

Debug Messages

Debug statements are the same as log statements, but `Debug` statements are orange in the Cloud Terminal. Use these statements when you want to give more attention to a message in the Cloud Terminal. Debug messages can be up to 200 characters in length. If you send multiple debug statements within 1 second, your messages are rate-limited to avoid crashing your browser.

```
PY
self.Debug("My debug message")
```

Error Messages

Error statements are the same as log statements, but `Error` statements are displayed in red text in the Cloud Terminal.

Use these statements when you want to give the most attention to a message in the Cloud Terminal. Error statements are rate-limited like debug statements.

```
self.Error("My error message")
```

Quit Messages

Quit statements cause your project to stop running and may log some data to the log file and Cloud Terminal. These statements are orange in the Cloud Terminal. When you call the `Quit` method, the program continues executing until the end of the method definition. If you want to quit execution immediately, `return` after you call `Quit` .

```
self.Quit("My quit message")
```

Runtime Statistics

Runtime statistics show the performace of your algorithm at a single moment in time.

The following table describes the default runtime statistics:

Statistic	Description
Capacity	The maximum amount of money an algorithm can trade before its performance degrades from market impact.
Equity	The total portfolio value if all of the holdings were sold at current market rates.
Fees	The total quantity of fees paid for all the transactions.
Holdings	The absolute sum of the items in the portfolio.
Net Profit	The dollar-value return across the entire trading period.
PSR	The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark (1).
Return	The rate of return across the entire trading period.
Unrealized	The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread.
Volume	The total value of assets traded for all of an algorithm's transactions.

The capacity statistic is only available for backtests.

To add a custom runtime statistic, call the `SetRuntimeStatistic` method with a `name` and `value` . The `value` argument can be a `string` or a number.

```
self.SetRuntimeStatistic(name, value)
```

Access Logs and Statistics

The following tables describe how to access the logs and runtime statistics, depending on how to deploy your algorithms.

QuantConnect Cloud Deployments

The following table describes how to access the logs and runtime statistics of algorithms you deploy in QuantConnect Cloud:

Execution Type	Result Type	Access Tools
Backtest	Logs	• Backtest results page in the Algorithm Lab • Backtest results page on Local Platform
Backtest	Runtime Statistics	• Backtest results page in the Algorithm Lab • Backtest results page on Local Platform • ReadBacktest API method • /backtests/read endpoint
Live Trading	Logs	• Live results page in the Algorithm Lab • Live results page on Local Platform • /live/read/log endpoint
Live Trading	Runtime Statistics	• Live results page in the Algorithm Lab • Live results page on Local Platform • ReadLiveAlgorithm API method • /live/read endpoint

On-Premise Deployments

The following table describes how to access the logs and runtime statistics of algorithms you deploy on-premise:

Execution Type	Result Type	Access Tools
Backtest	Logs	• Backtest results page on Local Platform • **<organizationWorkspace> / <projectName> / backtests / <unixTimestamp> / <algorithmId>-log.txt** • lean logs CLI command
Backtest	Runtime Statistics	• Backtest results page on Local Platform • **<organizationWorkspace> / <projectName> / backtests / <unixTimestamp> / <algorithmId>.json**
Live Trading	Logs	• Live results page on Local Platform • **<organizationWorkspace> / <projectName> / live / <timeStamp> / / L-<deploymentId>-log.txt** • lean logs CLI command
Live Trading	Runtime Statistics	• Live results page on Local Platform • **<organizationWorkspace> / <projectName> / live / <timeStamp> / / L-<deploymentId>.json**

Live Trading

QuantConnect enables you to run your algorithms in live mode with real-time market data. You can use the same algorithm for backtesting and live trading with different brokerages and data feeds.

Key Concepts

Live Trading

Key Concepts

Introduction

Algorithms should generally work seamlessly shifting from backtesting to live trading with no changes required. In backtesting algorithm events are triggered as fast as possible, whereas in live trading events are triggered in realtime.

Algorithm Portfolio

The live trading algorithm portfolio is loaded from the brokerage holdings, including open orders. When there are unsupported asset types in the portfolio the live trading strategy is stopped as we cannot be sure how to model the asset.

In paper trading the algorithm starts from no portfolio, and attempts to remember the previous portfolio state from the last time the portfolio was deployed.

Your algorithm should not assume it starts from an empty portfolio as you may have holdings from previous deployments.

Stateful Strategies

There is no automatic state management of live strategies in QuantConnect. We recommend algorithms reconstruct state or indicator needs using the WarmUp and History methods.

Once the algorithm has warmed up some objects you can use the Object Store to save the data for the next algorithm restart.

In the event the algorithm is terminated unexpectedly, you should review the live algorithm portfolio at the brokerage to confirm it will behave as expected.

Data Delivery Times

Most data is available at the same time as in backtesting, with the exception of daily data which is often delayed by 4-8 hours (4am - 8am).

US Equities universe selection data is processed at 7-8am ET.

Other Brokerages

If we do not support your brokerage reach out to let us and we can attempt to add them to the roadmap. With enough community requests we can build and open-source the brokerage integration.

Live Trading

Brokerages

Introduction

Brokerages provide you with a connection to the market so you can fill trades. To avoid placing invalid orders for execution in live trading, LEAN validates your orders before sending them to the real brokerage. To view all of the integrated brokerages, see Brokerages .

Portfolio

In live trading, LEAN populates the `Portfolio` object with your account holdings and the `Transactions` object with your open positions. If you don't manually subscribe to the assets in your account, LEAN subscribes to them with the lowest resolution of the subscriptions in your algorithm. For example, say you hold AAPL shares in your account and create the following subscriptions in your algorithm:

```
self.AddEquity("SPY", Resolution.Hour)
self.AddEquity("MSFT", Resolution.Second)
```

In this case, LEAN subscribes to second-resolution data for AAPL since the lowest resolution in your algorithm is `Resolution.Second` .

Deposits and Withdraws

You can deposit and withdraw cash from your brokerage account while you run an algorithm that's connected to the account. We sync the algorithm's cash holdings with the cash holdings in your brokerage account every day at 7:45 AM Eastern Time (ET).

Monitor the Brokerage Connection

We notify your algorithm when your brokerage connection disconnects and reconnects.

Lost Connections

If the brokerage connection breaks, we notify your algorithm through the `OnBrokerageDisconnect` event handler.

```
def OnBrokerageDisconnect(self) -> None:
    self.Debug("Brokerage connection lost")
```

Restored Connections

When the brokerage connection restores after it disconnects, we notify your algorithm through the `OnBrokerageReconnect` event handler.

```
def OnBrokerageReconnect(self) -> None:
    self.Debug("Brokerage connection restored")
```

Example Algorithm

For a full example algorithm that implements the `OnBrokerageDisconnect` and `OnBrokerageReconnect` methods, see the BrokerageActivityEventHandlingAlgorithm in the LEAN GitHub repository.

Monitor Brokerage Messages

When your brokerage sends you a message, we notify your algorithm through the `OnBrokerageMessage` event handler.

```
def OnBrokerageMessage(self, message_event: BrokerageMessageEvent) -> None:
    self.Debug(f"Brokerage message received: {message_event.Message}")
```

`BrokerageMessageEvent` objects have the following attributes:

For a full example algorithm that implements the `OnBrokerageMessage` method, see the BrokerageActivityEventHandlingAlgorithm in the LEAN GitHub repository.

To handle brokerage messages outside of your algorithm class, create and set a `BrokerageMessageHandler` . For a full example, see the CustomBrokerageMessageHandlerAlgorithm in the LEAN GitHub repository.

Live Trading

Data Feeds

Introduction

Data feeds are a stream of asset prices and quotes delivered to your trading algorithm during live execution. You need live data feeds to inject data into your algorithm so that you can make real-time trading decisions and so that the values of the securities in your portfolio update in real-time. You can source data from QuantConnect or your brokerage. To view the available data feeds, see Data Feeds .

Bar Building

We aggregate ticks to build bars.

In live trading, bars are built using the exchange timestamps with microsecond accuracy. This microsecond-by-microsecond processing of the ticks can mean that the individual bars between live trading and backtesting can have slightly different ticks. As a result, it's possible for a tick to be counted in different bars between backtesting and live trading, which can lead to bars having slightly different open, high, low, close, and volume values.

Latency

Live data takes time to travel from the source to your algorithm. The data feed has a latency of 20-50 milliseconds. QuantConnect is not designed for high-frequency trading.

History Requests

In live trading, if you make a history request for minute data at noon and the history period covers the start of the previous day to the present moment, the data from the previous day will be backtest data. The data of the current day will be live data that we collected throughout the morning. If you make this history request in a backtest, you might get slightly different data for the current day because of post-processing from the data vendor.

Warm Up Periods

LEAN supports an automated fast-forward system called "Warm Up". It simulates winding back the clock from the time you deploy the algorithm. In a backest, this is the `StartDate` of your algorithm. In live trading, it's the current date. Warm Up is a great way to prepare your algorithm and its indicators for trading.

US Fundamental Data by Morningstar is limited to the last 30 days.

Live Trading

Trading and Orders

Introduction

LEAN has dozens of methods to create, update, and cancel orders. You can place orders automatically with helper methods or manually through methods on the algorithm API. You can fetch, update, and cancel manual orders with order tickets . As the state of your orders change, LEAN creates events that notify your algorithm.

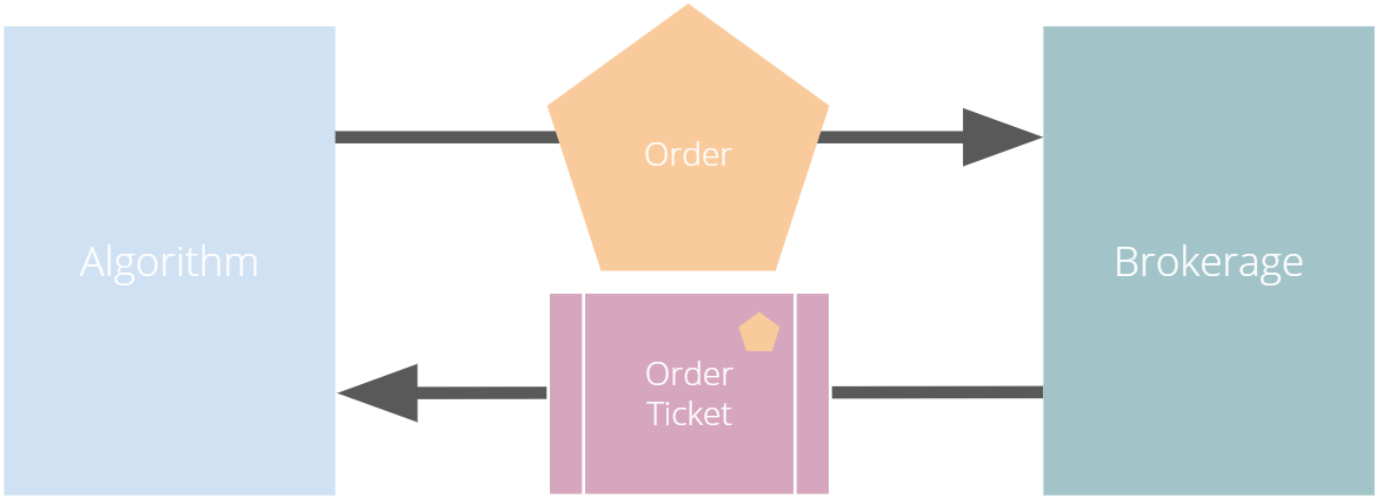
In backtesting, LEAN simulates order fills with historical data, but you can create your own fill, fee, slippage, and margin models via plugin points. You control how optimistic or pessimistic order fills are with transaction model classes. For more information about these types of models, see Reality Modeling .

In live trading, orders fill asynchronously. We send your order to the API of your brokerage and wait for their response to update the state of your algorithm and portfolio. The timing of live order fills doesn't depend on the resolution of your security subscriptions. When your order fills, the fill price and fee is set by your brokerage. You can add event handlers to your algorithm to monitor the brokerage connection and brokerage messages .

In backtesting, the trade fill timing depends on the resolution of your security subscription. For example, if you subscribe to a security with minute resolution data, the algorithm only receives data in one-minute time slices . As a result, the fill model can only evaluate if the order should fill on a minute-by-minute frequency.

Order Life Cycle

When you call one of the order methods to place an order, LEAN performs pre-order checks to ensure that the order meets some requirements and uses the last known price to check you have enough capital . To see the requirements of each order, see the **Requirements** section of the documentation for the order types and the **Orders** section of your brokerage model . If you can place the order, LEAN creates `Order` and OrderTicket objects. The order ticket is sent to your brokerage. As the brokerage processes your order, it returns another order ticket and it's compared against the order to see if the order is satisfied. Orders are asynchronous in live trading, so if you want to change an order, you must request it with the order ticket. Order changes are not guaranteed since your order may fill by the time brokerage receives the request.



When you create an order ticket, LEAN validates it to avoid sending orders that will be rejected by your brokerage. If the order is invalid, it's status is set to `OrderStatus.Invalid` . Otherwise, LEAN sets the order status to `OrderStatus.New` , sends the order to your brokerage, and waits for the brokerage message. If your brokerage accepts the order, the order status becomes `OrderStatus.Submitted` . Otherwise, it becomes `OrderStatus.Canceled` .

You can update orders until they fill or the brokerage prevents modifications. If you place an order update request, LEAN validates it to avoid sending orders that will be rejected by you brokerage. If the order update is valid, LEAN sends the update request and waits for the brokerage message. If your brokerage accepts the update, the order status becomes `OrderStatus.UpdateSubmitted` . Otherwise, it becomes `OrderStatus.Canceled` .

The brokerage notifies LEAN when you order fills (`OrderStatus.Filled`), partially fills (`OrderStatus.PartiallyFilled`) or is canceled (`OrderStatus.Canceled`). The brokerage can cancel your order before it completely fills. For example, if you place a market on open and the asset price moves before the market open to where you can't afford the quantity of the order, the brokerage rejects your order. The brokerage can also cancel your market on open order after partial fills if there is no shares left to trade.

Disable Buying Power

You can disable order margin checks and opt to let your brokerage decide to accept or reject the trades. This is helpful in live trading if you have a more permissive brokerage margin allowance that what LEAN models. The default position group buying power models are helpful for Option trading strategies. However, it can be counterproductive if it's not a supported Option strategy . To disable the validations of the default position group buying power model, use the `NullSecurityPositionGroupModel` . To set the `NullSecurityPositionGroupModel` for the portfolio, during initialization , call the `SetPositions` method with the `SecurityPositionGroupModel.Null` argument.

```
self.Portfolio.SetPositions(SecurityPositionGroupModel.Null)
```

PY

To disable the validations of the default buying power model , use the `NullBuyingPowerModel` . To set the `NullBuyingPowerModel` for a security subscription, call the `SetBuyingPowerModel` method with the `BuyingPowerModel.Null` argument.

```
equity = self.AddEquity("SPY")
equity.SetBuyingPowerModel(BuyingPowerModel.Null)
# Alias:
# equity.SetMarginModel(SecurityMarginModel.Null)
```

You can also set the asset `NullBuyingPowerModel` in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to set the buying power of securities in the security initializer, call `SetSecurityInitializer` before you create security subscriptions and after you call `SetBrokerageModel` .

```
# In Initialize
self.SetSecurityInitializer(MySecurityInitializer(self.BrokerageModel,
FuncSecuritySeeder(self.GetLastKnownPrices)))

# Outside of the algorithm class
class MySecurityInitializer(BrokerageModelSecurityInitializer):

    def __init__(self, brokerage_model: IBrokerageModel, security_seeder: ISecuritySeeder) -> None:
        super().__init__(brokerage_model, security_seeder)

    def Initialize(self, security: Security) -> None:
        # First, call the superclass definition
        # This method sets the reality models of each security using the default reality models of the
brokerage model
        super().Initialize(security)

        # Next, overwrite the security buying power
        security.SetBuyingPowerModel(BuyingPowerModel.Null)
```

Trading and Orders

Financial Advisors

Introduction

Financial Advisor accounts enable certified professionals to use a single trading algorithm to manage several client accounts. Our Interactive Brokers integration enables you to place FA group orders.

Group Routing

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```py
self.DefaultOrderProperties = InteractiveBrokersOrderProperties()
self.DefaultOrderProperties.FaGroup = "TestGroupEQ"
self.DefaultOrderProperties.FaMethod = "EqualQuantity"
self.DefaultOrderProperties.FaProfile = "TestProfileP"
self.DefaultOrderProperties.Account = "DU123456"
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `self.Portfolio["SPY"].Quantity` is zero.

Allocation Methods

The following table shows the supported allocation methods for FA group orders:

`FaMethod`	**Description**
`"EqualQuantity"`	Distributes shares equally between all accounts in the group. If you use this method, specify an order quantity.
`"NetLiq"`	Distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net liquidation value in each account and allocates shares based on these ratios. If you use this method, specify an order quantity.
`"AvailableEquity"`	Distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. If you use this method, specify an order quantity.
`"PctChange"`	Increases or decreases an already existing position. Positive percents increase positions and negative percents decrease positions. If you use this method, specify a percent instead of an order quantity.

```
def Initialize(self) -> None:
    # Set the default order properties
    self.DefaultOrderProperties = InteractiveBrokersOrderProperties()
    self.DefaultOrderProperties.FaGroup = "TestGroupEQ"
    self.DefaultOrderProperties.FaMethod = "EqualQuantity"
    self.DefaultOrderProperties.FaProfile = "TestProfileP"
    self.DefaultOrderProperties.Account = "DU123456"

def OnData(self, slice: Slice) -> None:
    # Override the default order properties
    # "NetLiq" requires a order size input
    order_properties = InteractiveBrokersOrderProperties()
    order_properties.FaMethod = "NetLiq"
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    # "AvailableEquity" requires a order size input
    order_properties.FaMethod = "AvailableEquity"
    self.LimitOrder(self.symbol, quantity, limit_price, orderProperties=order_properties)

    # "PctChange" requires a percentage of portfolio input
    order_properties.FaMethod = "PctChange"
    self.SetHoldings(self.symbol, pct_portfolio, orderProperties=order_properties)
```

PY

Subscription Requirements

To use FA group orders through our Interactive Brokers integration, you need to connect as a member of a Trading Firm and Institution organization. If you aren't currently on either of these tiers, upgrade your organization .

Live Trading

Reconciliation

Introduction

Algorithms usually perform differently between backtesting and live trading over the same time period. Backtests are simulations where we model reality as close as possible, but the modeling isn't always perfect. To measure the performance differences, we run an out-of-sample (OSS) backtest in parallel to all of your live trading deployments. The live results page displays the live equity curve and the OOS backtest equity curve of your algorithms.

If your algorithm is perfectly reconciled, it has an exact overlap between its live and OOS backtest equity curves. Deviations mean that the performance of your algorithm has differed between the two execution modes. Several factors can contribute to the deviations.

Differences From Data

The data that your algorithm uses can cause differences between backtesting and live trading performance.

Look-Ahead Bias

The Time Frontier minimizes the risk of look-ahead bias in backtests, but it does not completely eliminate the risk of look-ahead bias. For instance, if you use a custom dataset that contains look-ahead bias, your algorithm's live and backtest equity curves may deviate. To avoid look-ahead bias with custom datasets, set a `Period` on your custom data points so that your algorithm receives the data points after the `Time` + `Period` .

Discrete Time Steps

In backtests, we inject data into your algorithm at predictable times, according to the data resolution. In live trading, we inject data into your algorithm when new data is available. Therefore, if your algorithm has a condition with a specific time (i.e. time is 9:30:15), the condition may work in backtests but it will always fail in live trading since live data has microsecond precision. To avoid issues, either use a time range in your condition (i.e. 9:30:10 < time < 9:30:20), use a rounded time, or use a Scheduled Event.

Custom Data Emission Times

Custom data is often timestamped to midnight, but the data point may not be available in reality until several days after that point. If your custom dataset is prone to this delay, your backtest may not fetch the same data at the same time or frequency that your live trading algorithm receives the data, leading to deviations between backtesting and live trading. To avoid issues, ensure the timestamps of your custom dataset are the times when the data points would be available in reality.

In backtesting, LEAN and custom data are perfectly synchonized. In live trading, daily and hourly data from a custom data source are not because of the frequency that LEAN checks the data source depends on the `resolution` argument. The following table shows the polling frequency of each resolution:

Resolution	Update Frequency
Daily	Every 30 minutes
Hour	Every 30 minutes
Minute	Every minute
Second	Every second
Tick	Constantly checks for new data

Split Adjustment of Indicators

Backtests use adjusted price data by default. Therefore, if you don't change the data normalization mode , the indicators in your backtests are updated with adjusted price data. In contrast, if a split or dividend occurs in live trading, your indicators will temporarily contain price data from before the corporate event and price data from after the corporate event. If this occurs, your indicators will produce different signals in your backtests compared to your live trading deployment. To avoid issues, reset and warm up your indicators when your algorithm receives a corporate event.

Tick Slice Sizes

In backtesting, we collect ticks into slices that span 1 millisecond before injecting them into your algorithm. In live trading, we collect ticks into slices that span up to 70 milliseconds before injecting them into your algorithm. This difference in slice sizes can cause deviations between your algorithm's live and OOS backtest equity curves. To avoid issues, ensure your strategy logic is compatible with both slice sizes.

Differences From Modeling

The modeling that your algorithm uses can cause differences between backtesting and live trading performance.

Reality Modeling Error

We provide brokerage models to model fees, slippage, and order fills in backtests. However, these model predictions may not always match the fees that your live algorithm incurs, leading to deviations between backtesting and live trading. You can adjust the reality models that your algorithm uses to more accurately reflect the specific assets that you're trading. For more information about reality models, see Reality Modeling .

Market Impact

We don't currently model market impact. So, if you are trading large orders, your fill prices can be better during backtesting than live trading, causing deviations between backtesting and live trading. To avoid issues, implement a custom fill model in your backtests that incorporates market impact.

Fills

In backtests, orders fill immediately. In live trading, they are sent to your brokerage and take about half a second to execute. If you fill an order in a backtest with stale data, deviations between backtesting and live trading can occur because the order is filled at a price that is likely different from the real market price. Stale order fills commonly occur in backtests when you create a Scheduled Event with an incompatible data resolution. For instance, if you subscribe to hourly data, place a Scheduled Event for 11:15 AM, and fill an order during the Scheduled Event, the order will fill at a stale price because the data between 11:00 AM and 11:15 AM is missing. To avoid stale fills, only place orders when your algorithm receives price data.

In live trading, your brokerage provides the fill price of your orders. Since the backtesting brokerage models do not know the price at which live orders are filled, the fill price of backtest orders is based on the best price available in the current backtesting data. Similarly, limit orders can fill at different prices between backtesting and live trading. In backtesting, limit orders fill as soon as the limit price is hit. In live trading, your brokerage may fill the same limit order at a different price or fail to fill the order, depending on the position of your order in their order book.

Borrowing Costs

We do not currently simulate the cost of borrowing shorts in backtests. Therefore, if your algorithm takes short positions, deviations can occur between backtesting and live trading. We are working on adding the functionality to model borrowing fees. Subscribe to GitHub Issue #4563 to track the feature progress.

Differences From Brokerage

The brokerage that your algorithm uses can cause differences between backtesting and live trading performance.

Portfolio Allocations on Small Accounts

If you trade a small portfolio, it's difficult to achieve accurate portfolio allocations because shares are usually sold in whole numbers. For instance, you likely can't allocate exactly 10% of your portfolio to a security. You can use fractional shares to achieve accurate portfolio allocations, but not all brokerages support fractional shares. To get the closest results when backtesting and live trading over the same period, ensure both algorithms have the same starting cash balance.

Different Backtest Parameters

If you don't start your backtest and live deployment on the same date with the same holdings, deviations can occur between backtesting and live trading. To avoid issues, ensure your backtest parameters are the same as your live deployment.

Non-deterministic State From Algorithm Restarts

If you stop and redeploy your live trading algorithm, it needs to restart in a stateful way or else deviations can occur between backtesting and live trading. To avoid issues, redeploy your algorithm in a stateful way using the `SetWarmUp` and `History` methods. Furthermore, use the `ObjectStore` to save state information between your live trading deployments.

Existing Portfolio Securities

If you deploy your algorithm to live trading with a brokerage account that has existing holdings, your live trading equity curve reflects your existing positions, but the backtesting curve won't. Therefore, if you have existing positions in your brokerage account when you deploy your algorithm to live trading, deviations will occur between backtesting and live trading. To avoid issues, deploy your algorithm to live trading using a separate brokerage account or subaccount that does not have existing positions.

Brokerage Limitations

We provide brokerage models that support specific order types and model your buying power. In backtesting, we simulate your orders with the brokerage model you select. In live trading, we send your orders to your brokerage for execution. If the brokerage model that you use in backtesting is not the same brokerage that you use in live trading, deviations may occur between backtesting and live trading. The deviations can occur if your live brokerage doesn't support the order types that you use or if the backtesting brokerage models your buying power with a different methodology than the real brokerage. To avoid brokerage model issues, set the brokerage model in your backtest to the same brokerage that you use in live trading.

Differences From Third-Party Indicators

The values of our indicators can sometimes produce different results than the indicators on other platforms. These discrepancies can be a result of differences in the input data, timestamps, or implementation.

Price Differences

If you find differences in indicator values, compare the prices that are fed into the indicator on each platform. If the input data is slightly different, the indicator values will be different. To test if it's a difference in price data, feed in the data from the third-party platform into our indicators. We validate the indicators against third-party sources and when the values are the same, the indicator values are similar too.

Timestamp Differences

We timestamp our data to the time when the period ends. Many other platforms timestamp to the beginning of the candle.

Implementation Differences

Some indicators can have slightly different default arguments for their implementation. A common difference across platforms is to use a different `MovingAverageType` for the indicators. To view the default arguments for all our

indicators, see Supported Indicators . To view the full implementation of our indicators, see the LEAN GitHub repository .

Warm Up Period Differences

Some platforms use all of the historical data to warm up their indicators while LEAN indicators have a fixed number of bars they need to warm up. As a result, indicators with long memory like the Exponential Moving Average can have slightly different values across platforms.

Differences From Real-time Scheduled Events

In live trading, Scheduled Events execute in a parallel thread based on a real-time clock. If you set a Scheduled Event to fire at 10:00 AM, it executes at exactly 10:00 AM. In backtesting, Scheduled Events are part of the main algorithm manager loop, so they may not execute exactly when you set them. For example, if your algorithm subscribes to minute resolution US Equity data with regular trading hours and you set a Scheduled Event to occur at 2:00 AM, your Scheduled Event will execute at 9:31 AM when the next bar is fed into your algorithm.

The difference between live trading and backtesting is important to note because it can affect your algorithm's behavior. There are two common scenarios to consider.

Execution Timing and Backtest Timeouts

Take the following scenario:

- You set Scheduled Events for 2:00 AM, 3:00 AM, and 4:00 AM each day.
- Each Scheduled Event takes eight minutes to execute.
- Your algorithm only subscribes to US Equity securities without extended market hours (9:30 AM - 4:00 PM).

In this scenario, the Scheduled Events each fire at the correct time and execute without error in live trading. In backtesting, all of the Scheduled Events execute at 9:31 AM when your algorithm receives the first bar of the trading day. Since all the Scheduled Events take eight minutes to execute, the algorithm tries to execute all the Scheduled Events but reaches the 10-minute timeout and the backtest stops execution.

Live Data Delays

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them milliseconds after the top of each minute. Take the following scenario:

- You subscribe to minute resolution data
- You set a Scheduled Event for 10:00 AM
- The Scheduled Event checks the current asset price

In live trading, the Scheduled Event executes at exactly 10:00 AM but your algorithm may receive the 9:59-10:00 AM bar at 10:00:00.01 AM. Therefore, when you check the price in the Scheduled Event, the price from the 9:58-9:59 AM bar is the latest price. In backtesting, the Scheduled Event gets the price from the 9:59-10:00 AM bar since your algorithm receives the bar at perfect timing.

Live Trading

Notifications

Introduction

Set up some live trading notifications so that you are notified of market events and your algorithm's performance. QuantConnect Cloud supports email, SMS, webhooks, and Telegram notifications for live trading algorithms. If you run local algorithm with LEAN or the LEAN CLI, the notification services aren't available. To view the number of notification you can send for free in QuantConnect Cloud, see the Live Trading Notification Quotas .

Email

Email notifications can include up to 10KB of text content in the message body. These notifications can be slow since they go through your email provider. If you don't receive an email notification that you're expecting, check your junk folders.

To send email notifications in your code files, run:

```
self.Notify.Email(email_address, subject, body, attachment, headers)
```

SMS

SMS notifications are the only type of notification that you don't need an internet connection to receive.

To send SMS notifications in your code files, run:

```
self.Notify.Sms(phone_number, message)
```

Webhooks

Webhook notifications are an HTTP-POST request to a URL you provide. The request is sent with a timeout of 300s. You can process these notifications on your web server however you want. For instance, you can inject the content of the notifications into your server's database or use it to create other notifications on your own server.

To send webhook notifications in your code files, run:

```
self.Notify.Web(url, data, headers)
```

Telegram

Telegram notifications are automated messages to a Telegram group.

To send Telegram notifications in your code files, run:

```
self.Notify.Telegram(id, message, token)
```

The `id` argument is your Telegram group Id. Your group Id is in the URL when you open your group chat in the Telegram web interface. For example, the group Id of **web.telegram.org/z/#-503016366** is -503016366.

The `token` optional argument is a token of a bot you must add to your Telegram group. To create a bot, chat with @BotFather and follow its instructions. If you want to use our bot, the username is @quantconnect_notifications_bot.

To add emoticons to your `message` , convert the emoticon character to UTF-32 with the Unicode Converter on the Branah website. For example, the rocket emoji is `0001f680` in UTF-32 format, so use `\U001f680` in your message.

Terms of Use

The notification system can't be used for data distribution.

Live Trading

Charting and Logging

Introduction

The live results page shows your algorithm's live trading performance. You can add custom charts and logs to the results page.

Charting

Custom charts are limited to 4,000 data points. Intensive charting requires hundreds of megabytes of data, which is too much to stream online or display in a web browser. If you exceed the quota, the following message displays:

Exceeded maximum points per chart, data skipped

You can create up to 10 custom chart series per algorithm. If you exceed the quota, your algorithm stops executing and the following message displays:

Exceeded maximum series count: Each backtest can have up to 10 series in total.

In live trading, charts are sampled every one and ten minutes. If you create 1-minute resolution custom charts, the IDE charting will downgrade the granularity and display the 10-minutes sampling after a certain amount of samples.

Logging

Algorithms can record string messages ('log statements') to a file for analysis after a backtest is complete, or as a live algorithm is running. These records can assist in debugging logical flow errors in the project code. Consider adding them in the code block of an `if` statement to signify an error has been caught.

It's good practice to add logging statements to live algorithms so you can understand its behavior and keep records to compare against backtest results. If you don't add logging statements to a live algorithm and the algorithm doesn't trade as you expect, it's difficult to evaluate the underlying problem.

If you run algorithms on QuantConnect, you must stay within the log quota . To only log when your algorithm is live, use the `LiveMode` property.

```py
if self.LiveMode:
    self.Log("My log message")
```

Runtime Statistics

Runtime statistics show the performace of your algorithm at a single moment in time.

The following table describes the default runtime statistics:

Statistic	Description
Equity	The total portfolio value if all of the holdings were sold at current market rates.
Fees	The total quantity of fees paid for all the transactions.
Holdings	The absolute sum of the items in the portfolio.
Net Profit	The dollar-value return across the entire trading period.
PSR	The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark (1).
Return	The rate of return across the entire trading period.
Unrealized	The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread.
Volume	The total value of assets traded for all of an algorithm's transactions.

To add a custom runtime statistic, call the `SetRuntimeStatistic` method with a `name` and `value` . The `value` argument can be a `string` or a number.

```
self.SetRuntimeStatistic(name, value)
```

Signal Exports

CrunchDAO

Introduction

CrunchDAO is a service that connects strategy developers and capital allocators. With our CrunchDAO integration, you can send trading signals from your live algorithms to the CrunchDAO .

Add Providers

To export signals to CrunchDAO from your algorithm, during initialization , add a CrunchDAO signal export provider.

```py
self.SignalExport.AddSignalExportProviders(CrunchDAOSignalExport(apiKey, model, submissionName, comment))
```

The `CrunchDAOSignalExport` constructor accepts the following arguments:

Argument: `apiKey`

Your CrunchDAO API key. To get your API key, see the Profile > Settings page on the CrunchDAO website.

Data Type: `str` | Default Value: None

Argument: `model`

The Id of your CrunchDAO model. To create a new model or to get the Id of an existing model, see the Profile > Alpha page on the CrunchDAO website.

Data Type: `str` | Default Value: None

Argument: `submissionName`

A name for the submission to distinguish it from your other submissions.

Data Type: `str` | Default Value: `""`

Argument: `comment`

A comment for the submission.

Data Type: `str` | Default Value: `""`

You can add multiple signal export providers to a single algorithm.

Asset Classes

Our CrunchDAO integration supports signals for US Equities .

Universe Selection

The CrunchDAO skeleton contains the universe constituents. To load it into your algorithm, follow these steps:

1. Define a custom universe type .

```
class CrunchDaoSkeleton(PythonData):

    def GetSource(self, config, date, isLive):
        return SubscriptionDataSource("https://tournament.crunchdao.com/data/skeleton.csv",
SubscriptionTransportMedium.RemoteFile)

    def Reader(self, config, line, date, isLive):
        if not line[0].isdigit(): return None
        skeleton = CrunchDaoSkeleton()
        skeleton.Symbol = config.Symbol

        try:
            csv = line.split(',')
            skeleton.EndTime = (datetime.strptime(csv[0], "%Y-%m-%d")).date()
            skeleton.Symbol =  Symbol(SecurityIdentifier.GenerateEquity(csv[1], Market.USA,
mappingResolveDate=skeleton.Time), csv[1])
            skeleton["Ticker"] = csv[1]

        except ValueError:
            # Do nothing
            return None

        return skeleton
```

2. In the `Initialize` method, initialize the universe .

```
self.AddUniverse(CrunchDaoSkeleton, "CrunchDaoSkeleton", Resolution.Daily, self.select_symbols)
```

3. In the algorithm class, define the selector function to select all of the securities in the skeleton file.

```
def select_symbols(self, data: List[CrunchDaoSkeleton]) -> List[Symbol]:
    return [x.Symbol for x in data]
```

Schedule Submissions

CrunchDAO provides a new skeleton every Saturday at 6 PM Coordinated Universal Time (UTC). To schedule your submissions for before the market opens each week, during initialization, you can create a Scheduled Event .

```
self.week = -1
self.Schedule.On(
    self.DateRules.Every([DayOfWeek.Monday, DayOfWeek.Tuesday, DayOfWeek.Wednesday, DayOfWeek.Thursday,
DayOfWeek.Friday]),
    self.TimeRules.At(13, 15, TimeZones.Utc),
    self.submit_signals)
```

The preceding Scheduled Event calls the `submit_signals` method every weekday at 1:15 PM UTC. Define this method to create and send portfolio targets to CrunchDAO.

```py
def submit_signals(self):
    if self.IsWarmingUp:
        return

    # Submit signals once per week
    week_num = self.Time.isocalendar()[1]
    if self.week == week_num:
        return
    self.week = week_num

    symbols = [security.Symbol for security in self.crunch_universe if security.Price > 0]

    # Get historical price data
    # close_prices = self.History(symbols, 22, Resolution.Daily).close.unstack(0)

    # Create portfolio targets
    weight_by_symbol = {symbol: 1/len(symbols) for symbol in symbols} # Add your logic here
    targets = [PortfolioTarget(symbol, weight) for symbol, weight in weight_by_symbol.items()]

    # (Optional) Place trades
    self.SetHoldings(targets)

    # Send signals to CrunchDAO
    success = self.SignalExport.SetTargetPortfolio(targets)
    if not success:
        self.Debug(f"Couldn't send targets at {self.Time}")
```

For more information about requesting historical price and alternative data, see History Requests .

Send Portfolio Targets

To send your current portfolio holdings, call the `SetTargetPortfolioFromPortfolio` method. The method returns a boolean that represents if the targets were successfully sent to CrunchDAO.

```py
success = self.SignalExport.SetTargetPortfolioFromPortfolio()
```

To send targets that aren't based on your current portfolio holdings, pass a `PortfolioTarget` object or a list of `PortfolioTarget` objects to the `SetTargetPortfolio` method. In this situation, the number you pass to the `PortfolioTarget` constructor represents the portfolio weight. Don't use the `PortfolioTarget.Percent` method.

```py
target = PortfolioTarget(self.symbol, weight)
success = self.SignalExport.SetTargetPortfolio(target)
```

Signal Requirements

When you submit signals to CrunchDAO, abide by the following rules:

- All signals must have a quantity between 0 and 1 (inclusive).
- Submit one signal per round. If you submit more than one signal in a round, your new submission overwrites the previous one.
- Send signals for at least half of the investment universe.

Signal Exports

Numerai

Introduction

Numerai is a platform where you can earn rewards by uploading unique live trading signals for a universe of US Equities. The regular Numerai Tournament is built around a free dataset they provide , but with Numerai Signals , you can now use any dataset to generate your trading signals. Through our Numerai integration, you can use our rich library of alternative datasets or your own custom datasets to create and automate your Numerai Signal submissions.

Add Providers

To export signals to Numerai from your algorithm, during initialization , add a Numerai signal export provider.

```
self.SignalExport.AddSignalExportProviders(NumeraiSignalExport(publicId, secretId, modelId, fileName))
```

The `NumeraiSignalExport` constructor accepts the following arguments:

Argument: `publicId`

Your Numerai API key. To create and view your API keys, see the **Automation** section of your Account page on the Numerai website.

Data Type: `str` | Default Value: None

Argument: `secretId`

Your Numerai API secret. You get your API secret when you create a new API key.

Data Type: `str` | Default Value: None

Argument: `modelId`

The Id of the Numerai model. Follow these steps to get the model Id:

1. Open the Models page on the Numerai website.
2. In the **Models** section, click the **three dots** next to a model.
3. Click **Copy Model ID** .

Data Type: `str` | Default Value: `""`

Argument: `fileName`

The name for the signal file. If you use a file name that already exists, the new file overwrites the old one.

Data Type: `str` | Default Value: `"predictions.csv"`

You can add multiple signal export providers to a single algorithm.

Asset Classes

Our Numerai integration supports signals for US Equities .

Universe Selection

The Numerai Signals stock market universe covers roughly the top 5,000 largest stocks in the world. The universe available on QuantConnect that's the closest match to the Numerai Signals universe is the CRSP US Total Market Index, which represents approximately 100% of the investable US Equity market regularly traded on the New York Stock Exchange and Nasdaq. This Index doesn't contain all of the stocks in the Numerai Signals universe, but you don't need to submit signals for all the stocks in the Numerai Signals universe.

To get the constituents of the CRSP US Total Market Index, add an ETF constituents universe for the Vanguard Total Stock Market ETF, VTI.

```
self.etf_symbol = self.AddEquity("VTI").Symbol
self.AddUniverse(self.Universe.ETF(self.etf_symbol))
```

Schedule Submissions

Every Tuesday, Wednesday, Thursday, Friday, and Saturday of the week, a new round is open for you to submit signals. Saturday rounds open at 18:00 UTC, and the submission window is open until Monday 14:30 UTC. Weekday rounds open at 13:00 UTC, and the submission window is open for 1 hour. For more information about the competition rounds, see Rounds in the Numerai documentation.

To schedule your submissions, you can set a Scheduled Event during initialization.

```
self.Schedule.On(
    self.DateRules.EveryDay(self.etf_symbol),
    self.TimeRules.At(13, 0, TimeZones.Utc),
    self.submit_signals)
```

Send Portfolio Targets

To send targets, pass a list of `PortfolioTarget` objects to the `SetTargetPortfolio` method. The method returns a boolean that represents if the targets were successfully sent to Numerai Signals. In this situation, the number you pass to the `PortfolioTarget` constructor represents the portfolio weight. Don't use the `PortfolioTarget.Percent` method.

```
success = self.SignalExport.SetTargetPortfolio(targets)
```

Signal Requirements

When you submit signals to Numerai, abide by the following rules:

- All signals must have a quantity between 0 and 1 (exclusive)
- You must submit at least 10 different signals per submission
- At least one of the weights in every batch of signals must be unique

Strategy Library

Introduction

The Strategy Library is a collection of tutorials written by the QuantConnect team and community members. Review these tutorials to learn about trading strategies found in the academic literature and how to implement them with QuantConnect/LEAN.

Tutorials

Search Strategy Tutorials

Strategy Name
CAPM Alpha Ranking Strategy on Dow 30 Companies Applies CAPM model to rank Dow Jones 30 companies.
Combining Mean Reversion and Momentum in Forex Market Combines momentum and mean reversion techniques in the forex markets.
Pairs Trading-Copula vs Cointegration Applies Copula and Cointergration method to pairs trading.
The Dynamic Breakout II Strategy A demonstration of dynamic breakout II strategy.
Dual Thrust Trading Algorithm A demontration of Dual Thrust Intraday strategy.
Can Crude Oil Predict Equity Returns Applies regression method to predict the return from the stock market and compare it to the short-term U.S. T-bill rate.
Intraday Dynamic Pairs Trading using Correlation and Cointegration Approach A high frequency pairs trading algorithm based on cointegration.

Strategy Name
The Momentum Strategy Based on the Low Frequency Component of Forex Market Applies high frequency filter to the momentum strategy.
Stock Selection Strategy Based on Fundamental Factors MorningStar Fundamental factors universe selection algorithm.
Short-Term Reversal Strategy in Stocks A short term reversal algorithm which gives the opposite signal by analyzing recent period price action.
Fundamental Factor Long Short Strategy A basic monthly rebalance long short algorithm based on fundamental factors.
Asset Class Trend Following Selects ETFs over ten-month moving average and assigns an equally weighted allocation. Source: Quantpedia
Asset Class Momentum Selects ETFs in different asset classes with the highest momentum and assigns an equally weighted allocation. Source: Quantpedia
Residual Momentum Constructs a long/short portfolio based on trailing residual momentum normalized by its standard deviation Source: Quantpedia
Sector Momentum Selects ETFs in different sectors with the highest momentum and assigns an equally weighted allocation. Source: Quantpedia
Overnight Anomaly Buy SPY ETF at its closing price and sell it at the opening each day. Source: Quantpedia

Strategy Name
Forex Carry Trade Goes long the currency with the highest central bank interest rate and goes short the currency with the lowest interest rate. Source: Quantpedia
Volatility Effect in Stocks Constructs equally weighted portfolios by selecting stocks with the lowest volatility in the past one year. Source: Quantpedia
Forex Momentum Goes long currencies with strongest 12 month momentum against USD and goes short currencies with the lowest 12 month momentum against USD. Source: Quantpedia
Pairs Trading with Stocks Looks for the security that minimizes the sum of squared deviations and long-short position is opened when pair prices have diverged by multiple of standard deviations. Source: Quantpedia
Short Term Reversal Goes long stocks with the lowest return in the previous month and goes short stocks with the greatest return from the previous month. Source: Quantpedia
Momentum Effect in Stocks Goes long stocks with the best 12-month momentum in the large-cap universe. Source: Quantpedia
Momentum Effect in Country Equity Indexes Goes long stocks with the best 12-month momentum in the country equity indexes ETFs. Source: Quantpedia

Strategy Name
Mean Reversion Effect in Country Equity Indexes Goes long country equity indexes ETFs with the worst 36-month return and short ETFs with the best 36-month return. Source: Quantpedia
Liquidity Effect in Stocks Goes long stocks with the lowest turnover and short on stocks with the highest turnover from the lowest market-cap quartile. Source: Quantpedia
Volatility Risk Premium Effect Sells at-the-money straddle with one month until maturity and buys an offsetting 15% out-of-the-money puts each month. Source: Quantpedia
Momentum Effect in Commodities Futures Goes long commodity futures with the highest momentum and short on futures with the lowest momentum. Source: Quantpedia
Small Capitalization Stocks Premium Anomaly Goes long stocks with the lowest market capitalization and rebalances the portfolio once a year. Source: Quantpedia
Paired Switching Goes long asset with better performance over the last period and rebalances portfolio every quarter. Source: Quantpedia
Term Structure Effect in Commodities Buys each month the 20% of commodities with the highest roll-returns and shorts the 20% of commodities with the lowest roll-returns and holds the long-short positions for one month. Source: Quantpedia

Strategy Name
Momentum Effect Combined with Term Structure in Commodities Portfolios are formed based on roll returns and the algorithm goes long and short contracts with the highest and lowest one-month performance. Source: Quantpedia
Book-to-Market Value Anomaly Quintile portfolios are formed based on the Book-to-Market ratio and the highest quintile is held for one year. Source: Quantpedia
Gold Market Timing Goes long gold when the Fed model shows that the market is undervalued (the earnings yield is higher than the bond yield and their ratio is at least 2). Source: Quantpedia
Turn of the Month in Equity Indexes Buys SPY the day before the end of the month and liquidates position on 3rd trading day of new month. Source: Quantpedia
Momentum - Short Term Reversal Strategy Goes long stocks with the decreasing return from the winner group and short stocks with the increasing return from the loser group. Source: Quantpedia
Pairs Trading with Country ETFs Identifies the price divergence from two highly correlated country ETFs and takes a market neutral position. Source: Quantpedia
Sentiment and Style Rotation Effect in Stocks Creates long-short positions of growth and value stocks based on the investment sentiment. Source: Quantpedia

Strategy Name
Asset Growth Effect Creates long-short positions of stocks based on the annual change of their total assets. Source: Quantpedia
Momentum and State of Market Filters Goes long and short stocks with the highest and lowest six-month momentum respectively if the previous 12 months return on the broad market index was positive. Source: Quantpedia
Accrual Anomaly Decile portfolios are formed based on balance sheet based accruals and highest decile is shorted while lowest decile is bought for a year. Source: Quantpedia
Momentum in Mutual Fund Returns Forms a long-short portfolio of asset management firms based on trailing rate of change and nearness to trailing high. Source: Quantpedia
Momentum and Style Rotation Effect Goes long style index ETF with the highest 12-month momentum and short ETF with the lowest 12-month momentum. Source: Quantpedia
Trading with WTI BRENT Spread Goes long the spread if the spread is below 20-day moving average and short if the spread is above 20-day moving average. Source: Quantpedia

Strategy Name
Momentum Effect in REITs Tercile portfolios are formed based on momentum and the best performing portfolio is held. Source: Quantpedia
Option Expiration Week Effect Goes long S&P 100 index ETF during option expiration week and stays in cash during other days. Source: Quantpedia
Earnings Quality Factor Goes long stocks with high earnings quality and short stocks with low earnings quality based on composite factor score. Source: Quantpedia
January Effect in Stocks Invests into small cap stocks at the beginning of each January and stays invested in large cap stocks for rest of the year. Source: Quantpedia
Momentum and Reversal Combined with Volatility Effect in Stocks Goes long on stocks from the highest performing quintile from the highest volatility group and short on stocks from the lowest performing quintile from the highest volatility group. Source: Quantpedia
ROA Effect within Stocks Goes long on stocks with highest ROA and short stocks with the lowest ROA from each market capitalization group. Source: Quantpedia
January Barometer Invested in equity market with ETF only if January return is positive otherwise switch investments to T-Bills. Source: Quantpedia

Strategy Name
Lunar Cycle in Equity Market Goes long in emerging market index ETF 7 days before the new moon and switch to a short position on emerging market index ETF 7 days before the full moon. Source: Quantpedia
VIX Predicts Stock Index Returns Goes long on equity index ETF if the VIX is in the highest percentile short if VIX is in the lowest percentile in the last two-year history. Source: Quantpedia
Combining Momentum Effect with Volume Goes long stocks with the highest volume from the top momentum decile and short stocks with the highest volume from the bottom momentum decile. Source: Quantpedia
Short Term Reversal with Futures Goes long (short) on futures from the high-volume, low-open interest group with the lowest (greatest) returns in the previous week. Source: Quantpedia
Pre-holiday Effect Invests in equity market 2 days preceding holiday days and stays in cash during the other trading days. Source: Quantpedia
Beta Factors in Stocks Goes long stocks with the bottom beta and short stocks with the top beta, securities are weighted by the ranked betas. Source: Quantpedia

Strategy Name
Exploiting Term Structure of VIX Futures Buys or sells the nearest VIX futures based on the daily roll and hedge against the open positions with E-mini S&P500 futures. Source: Quantpedia
12 Month Cycle in Cross-Section of Stocks Returns Reviews the returns from last January, going long on the top 10% winners and short the bottom 10%. Source: Quantpedia
Momentum Effect in Stocks in Small Portfolios Goes long in the 10 stocks with the highest performance and goes short in the 10 stocks with the lowest performance in the previous one year. Source: Quantpedia
Value Effect within Countries Invests in the cheapest 33% of country ETFs according to CAPE ratios. Source: Quantpedia
Beta Factor in Country Equity Indexes Goes long on the low-beta portfolio and short on the high-beta portfolio in country indexes ETFs. Source: Quantpedia
Price to Earnings Anomaly Invests in stocks with low P/E ratio.
Fama French Five Factors Stock selecting strategy based on Fama-French Five Factors Model. Source: NYU

Strategy Name
Mean-Reversion Statistical Arbitrage Strategy in Stocks Apply statistical arbitrage to take advantage of pricing inefficiencies in stocks. Source: NYU
Expected Idiosyncratic Skewness Stock selection strategy that calculates expected idiosyncratic skewness using Fama-French three-factor model, sorts stocks based on the calculated skewness, and longs the bottom 5%. Source: NYU
Risk Premia in Forex Markets A strategy based on asymmetric tail risks and excess returns in forex markets. Source: NYU
Seasonality Effect based on Same-Calendar Month Returns A strategy that takes long and short positions based on historical same-calendar month returns Source: NYU
Standardized Unexpected Earnings Stock selection strategy that calculates the unexpected earnings, standardizes the unexpected earnings, goes long on the top 5%, and rebalances the portfolio monthly. Source: NYU
Price and Earnings Momentum A momentum strategy based on quarterly returns and earnings growth Source: NYU
Improved Momentum Strategy on Commodities Futures An advanced momentum strategy that modifies the basic momentum strategies by introducing Baltas and Kosowski weights and rebalances the portfolio monthly. The new weighing scheme incorporates trend strength into the trading signal, uses an efficient volatility estimator, and adds a dynamic leverage mechanism. Source: NYU

Strategy Name
Commodities Futures Trend Following A simple trend following strategy on commodities futures. Source: NYU
Forecasting Stock Prices using a Temporal CNN Model Applying a Temporal Convolutional Neural Network to forecasting future stock prices. Source: Tampere University
Leveraged ETFs with Systematic Risk Management We apply Simple Moving Averages to manage the risk of holding leveraged ETFs in an attempt to beat the S&P500 Source: The Lead-Lag Report
Ichimoku Clouds in the Energy Sector A techincal indicator crossover strategy trading the largest energy companies. Source: SSRN
Intraday ETF Momentum A momentum strategy based on returns of the market open Source: NYU
Intraday Arbitrage Between Index ETFs A strategy that tracks the price paths of two correlated ETFs and takes advantage of mis-pricings that arise when the price paths diverge Source: SSRN
Optimal Pairs Trading Mathematically Deriving the Optimal Entry and Liquidation Values of a Pairs Trading Process Source: arXiv

Strategy Name
G-Score Investing Applying G-Score Investing to Invest in a Portfolio of Technology Stocks Source: SSRN
SVM Wavelet Forecasting Forecasting EURJPY prices with an SVM Wavelet model Source: Academia
Gradient Boosting Model Forecasts future intraday returns with a gradient boosting model trained on technical indicators Source: arXiv
Using News Sentiment to Predict Price Direction of Drug Manufacturers Analyzes the news releases of drug manufacturers and places intraday trades for the stocks with positive news. Source: arXiv
Gaussian Naive Bayes Model Forecasts the next day's return of technology stocks by fitting a gaussian naive bayes model to the historical returns of the technology sector constituents. Source: Academia

Available QCAlgorithm Methods

All

Adding Data | Algorithm Framework | Charting | Consolidating Data | Handling Data | Historical Data | Indicators | Live Trading | Logging | Machine Learning | Modeling | Parameter and Optimization | Scheduled Events | Securities and Portfolio | Trading and Orders | Universes

ABANDS()	Creates a new Acceleration Bands indicator.
AD()	Creates a new AccumulationDistribution indicator.
AddAlpha()	Adds a new alpha model.
AddCfd()	Creates and adds a new `Cfd` security to the algorithm.
AddChart()	Add a Chart object to algorithm collection.
AddCrypto()	Creates and adds a new `Crypto` security to the algorithm.
AddCryptoFuture()	Creates and adds a new `CryptoFuture` security to the algorithm.
AddData()	AddData a new user defined data source, requiring only the minimum config options. The data is added with a default time zone of NewYork (Eastern Daylight Savings Time). This method is meant for custom data types that require a ticker, but have no underlying

INDICATORS

ABANDS() 1/1

```
AccelerationBands QuantConnect.Algorithm.QCAlgorithm.ABANDS (
Symbol symbol,
Int32 period,
*Decimal width,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new Acceleration Bands indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Acceleration Bands we want.
`Int32`	period	The period of the three moving average (middle, upper and lower band).
`*Decimal`	width	*(Optional)* A coefficient specifying the distance between the middle band and upper or lower bands.
`*MovingAverageType`	movingAverageType	*(Optional)* Type of the moving average. *Options: ['Simple', 'Exponential', 'Wilders', 'LinearWeightedMovingAverage', 'DoubleExponential', 'TripleExponential', 'Triangular', 'T3', 'Kama', 'Hull', 'Alma']*
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AccelerationBands` - The new `AccelerationBands` object.

Definition at line 46 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

AD() 1/1

```
AccumulationDistribution QuantConnect.Algorithm.QCAlgorithm.AD (
 Symbol symbol,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates a new AccumulationDistribution indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose AD we want.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AccumulationDistribution` - The AccumulationDistribution indicator for the requested symbol over the specified period.

Definition at line 64 of file Algorithm/QCAlgorithm.Indicators.cs.

ALGORITHM FRAMEWORK

AddAlpha() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.AddAlpha (
IAlphaModel alpha
)
```

Adds a new alpha model.

Show Details

Parameters		
`IAlphaModel`	alpha	Model that generates alpha to add.

Return

`Void` - This method provides no return.

Definition at line 326 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK

AddAlpha() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.AddAlpha (
PyObject alpha
)
```

Adds a new alpha model.

Show Details

Parameters		
PyObject	alpha	Model that generates alpha to add.

Return

`Void` - This method provides no return.

Definition at line 49 of file Algorithm/QCAlgorithm.Framework.Python.cs.

ADDING DATA

AddCfd() 1/1

```
Cfd QuantConnect.Algorithm.QCAlgorithm.AddCfd (
String ticker,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward,
*Decimal leverage
)
```

Creates and adds a new `Cfd` security to the algorithm.

Show Details

Parameters		
`String`	ticker	The currency pair.
`*Nullable< Resolution >`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The cfd trading market, See also: `Market` . . Default value is None and looked up using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .

Return

`Cfd` - The new security.

Definition at line 2167 of file Algorithm/QCAlgorithm.cs.

CHARTING

AddChart() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.AddChart (
Chart chart
)
```

Add a Chart object to algorithm collection.

Show Details

Parameters		
`Chart`	chart	Chart object to add to collection.

Return

`Void` - This method provides no return.

Definition at line 53 of file Algorithm/QCAlgorithm.Plotting.cs.

ADDING DATA

AddCrypto() 1/1

```
Crypto QuantConnect.Algorithm.QCAlgorithm.AddCrypto (
String ticker,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward,
*Decimal leverage
)
```

Creates and adds a new `Crypto` security to the algorithm.

Show Details

Parameters		
`String`	ticker	The currency pair.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The cfd trading market, See also: `Market` . . Default value is None and looked up using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .

Return

`Crypto` - The new security.

Definition at line 2198 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddCryptoFuture() 1/1

```
CryptoFuture QuantConnect.Algorithm.QCAlgorithm.AddCryptoFuture (
String ticker,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward,
*Decimal leverage
)
```

Creates and adds a new `CryptoFuture` security to the algorithm.

Show Details

Parameters		
`String`	ticker	The currency pair.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The cfd trading market, See also: `Market` . . Default value is None and looked up using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .

Return

`CryptoFuture` - The new security.

Definition at line 2213 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddData() 1/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
PyObject type,
String ticker,
*Nullable<Resolution> resolution
)
```

AddData a new user defined data source, requiring only the minimum config options. The data is added with a default time zone of NewYork (Eastern Daylight Savings Time). This method is meant for custom data types that require a ticker, but have no underlying Symbol. Examples of data sources that meet this criteria are U.S. Treasury Yield Curve Rates and Trading Economics data.

Show Details

Parameters		
`PyObject`	type	Data source type.
`String`	ticker	Key/Ticker for data.
`*Nullable<Resolution>`	resolution	*(Optional)* Resolution of the data.

Return

`Security` - The new `Security` object.

Definition at line 62 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA

AddData() 2/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
PyObject type,
Symbol underlying,
*Nullable<Resolution> resolution
)
```

AddData a new user defined data source, requiring only the minimum config options. The data is added with a default time zone of NewYork (Eastern Daylight Savings Time). This adds a Symbol to the `Underlying` property in the custom data Symbol object. Use this method when adding custom data with a ticker from the past, such as "AOL" before it became "TWX", or if you need to filter using custom data and place trades on the Symbol associated with the custom data.

Show Details

Parameters		
`PyObject`	type	Data source type.
`Symbol`	underlying	The underlying symbol for the custom data.
`*Nullable<Resolution>`	resolution	*(Optional)* Resolution of the data.

Return

`Security` - The new `Security` object.

Definition at line 86 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA

AddData() 3/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
PyObject type,
String ticker,
Nullable<Resolution> resolution,
DateTimeZone timeZone,
*Boolean fillForward,
*Decimal leverage
)
```

AddData a new user defined data source, requiring only the minimum config options. This method is meant for custom data types that require a ticker, but have no underlying Symbol. Examples of data sources that meet this criteria are U.S. Treasury Yield Curve Rates and Trading Economics data.

Show Details

Parameters		
PyObject	type	Data source type.
String	ticker	Key/Ticker for data.
Nullable<Resolution>	resolution	Resolution of the Data Required.
DateTimeZone	timeZone	Specifies the time zone of the raw data.
*Boolean	fillForward	*(Optional)* When no data available on a tradebar, return the last data that was generated.
*Decimal	leverage	*(Optional)* Custom leverage per security.

Return

`Security` - The new `Security` object.

Definition at line 104 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA

AddData() 4/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
PyObject type,
Symbol underlying,
Nullable<Resolution> resolution,
DateTimeZone timeZone,
*Boolean fillForward,
*Decimal leverage
)
```

AddData a new user defined data source, requiring only the minimum config options. This adds a Symbol to the `Underlying` property in the custom data Symbol object. Use this method when adding custom data with a ticker from the past, such as "AOL" before it became "TWX", or if you need to filter using custom data and place trades on the Symbol associated with the custom data.

Show Details

Parameters		
PyObject	type	Data source type.
Symbol	underlying	The underlying symbol for the custom data.
Nullable<Resolution>	resolution	Resolution of the Data Required.
DateTimeZone	timeZone	Specifies the time zone of the raw data.
*Boolean	fillForward	*(Optional)* When no data available on a tradebar, return the last data that was generated.
*Decimal	leverage	*(Optional)* Custom leverage per security.

Return

`Security` - The new `Security` object.

Definition at line 130 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA

AddData() 5/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
Type dataType,
String ticker,
Nullable<Resolution> resolution,
DateTimeZone timeZone,
*Boolean fillForward,
*Decimal leverage
)
```

AddData a new user defined data source, requiring only the minimum config options. This method is meant for custom data types that require a ticker, but have no underlying Symbol. Examples of data sources that meet this criteria are U.S. Treasury Yield Curve Rates and Trading Economics data.

Show Details

Parameters		
`Type`	dataType	Data source type.
`String`	ticker	Key/Ticker for data.
`Nullable<Resolution>`	resolution	Resolution of the Data Required.
`DateTimeZone`	timeZone	Specifies the time zone of the raw data.
`*Boolean`	fillForward	*(Optional)* When no data available on a tradebar, return the last data that was generated.
`*Decimal`	leverage	*(Optional)* Custom leverage per security.

Return

`Security` - The new `Security` object.

Definition at line 148 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA

AddData() 6/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
Type dataType,
Symbol underlying,
*Nullable<Resolution> resolution,
*DateTimeZone timeZone,
*Boolean fillForward,
*Decimal leverage
)
```

AddData a new user defined data source, requiring only the minimum config options. This adds a Symbol to the `Underlying` property in the custom data Symbol object. Use this method when adding custom data with a ticker from the past, such as "AOL" before it became "TWX", or if you need to filter using custom data and place trades on the Symbol associated with the custom data.

Show Details

Parameters		
`Type`	dataType	Data source type.
`Symbol`	underlying	/
`*Nullable<Resolution>`	resolution	*(Optional)* Resolution of the Data Required.
`*DateTimeZone`	timeZone	*(Optional)* Specifies the time zone of the raw data.
`*Boolean`	fillForward	*(Optional)* When no data available on a tradebar, return the last data that was generated.
`*Decimal`	leverage	*(Optional)* Custom leverage per security.

Return

`Security` - The new `Security` object.

Definition at line 193 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA

AddData() 7/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
PyObject type,
String ticker,
SymbolProperties properties,
SecurityExchangeHours exchangeHours,
*Nullable<Resolution> resolution,
*Boolean fillForward,
*Decimal leverage
)
```

AddData a new user defined data source including symbol properties and exchange hours, all other vars are not required and will use defaults. This overload reflects the C# equivalent for custom properties and market hours.

Show Details

Parameters		
PyObject	type	Data source type.
String	ticker	Key/Ticker for data.
SymbolProperties	properties	The properties of this new custom data.
SecurityExchangeHours	exchangeHours	The Exchange hours of this symbol.
*Nullable<Resolution>	resolution	*(Optional)* Resolution of the Data Required.
*Boolean	fillForward	*(Optional)* When no data available on a tradebar, return the last data that was generated.
*Decimal	leverage	*(Optional)* Custom leverage per security.

Return

Security - The new Security object.

Definition at line 213 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA

AddData() 8/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
 String ticker,
 *Nullable<Resolution> resolution
)
```

Show Details

Parameters		
String	ticker	/
*Nullable<Resolution>	resolution	*(Optional)* /

Return

Security - The new Security object.

Definition at line 2323 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddData() 9/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
 Symbol underlying,
 *Nullable<Resolution> resolution
)
```

Show Details

Parameters		
Symbol	underlying	/
*Nullable<Resolution>	resolution	*(Optional)* /

Return

Security - The new Security object.

Definition at line 2342 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddData() 10/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
 String ticker,
 Nullable<Resolution> resolution,
 Boolean fillForward,
 *Decimal leverage
)
```

Show Details

Parameters		
String	ticker	/
Nullable<Resolution>	resolution	/
Boolean	fillForward	/
*Decimal	leverage	*(Optional)* /

Return

Security - The new Security object.

Definition at line 2364 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddData() 11/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
 Symbol underlying,
 Nullable<Resolution> resolution,
 Boolean fillForward,
 *Decimal leverage
)
```

Show Details

Parameters		
Symbol	underlying	/
Nullable<Resolution>	resolution	/
Boolean	fillForward	/
*Decimal	leverage	*(Optional)* /

Return

Security - The new Security object.

Definition at line 2381 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddData() 12/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
String ticker,
Nullable<Resolution> resolution,
DateTimeZone timeZone,
*Boolean fillForward,
*Decimal leverage
)
```

Show Details

Parameters		
String	ticker	/
Nullable<Resolution>	resolution	/
DateTimeZone	timeZone	/
*Boolean	fillForward	*(Optional)* /
*Decimal	leverage	*(Optional)* /

Return

Security - The new Security object.

Definition at line 2398 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddData() 13/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
Symbol underlying,
Nullable<Resolution> resolution,
DateTimeZone timeZone,
*Boolean fillForward,
*Decimal leverage
)
```

Show Details

Parameters		
`Symbol`	underlying	/
`Nullable<Resolution>`	resolution	/
`DateTimeZone`	timeZone	/
`*Boolean`	fillForward	*(Optional)* /
`*Decimal`	leverage	*(Optional)* /

Return

`Security` - The new `Security` object.

Definition at line 2415 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddData() 14/14

```
Security QuantConnect.Algorithm.QCAlgorithm.AddData (
String ticker,
SymbolProperties properties,
SecurityExchangeHours exchangeHours,
*Nullable<Resolution> resolution,
*Boolean fillForward,
*Decimal leverage
)
```

Show Details

Parameters		
`String`	ticker	/
`SymbolProperties`	properties	/
`SecurityExchangeHours`	exchangeHours	/
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Boolean`	fillForward	*(Optional)* /
`*Decimal`	leverage	*(Optional)* /

Return

`Security` - The new `Security` object.

Definition at line 2433 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddEquity() 1/1

```
Equity QuantConnect.Algorithm.QCAlgorithm.AddEquity (
String ticker,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward,
*Decimal leverage,
*Boolean extendedMarketHours,
*Nullable<DataNormalizationMode> dataNormalizationMode
)
```

Creates and adds a new `Equity` security to the algorithm.

Show Details

Parameters		
`String`	ticker	The equity ticker symbol.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The equity's market, See also: `Market` . . Default value is None and looked up using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .
`*Boolean`	extendedMarketHours	*(Optional)* True to send data during pre and post market sessions. Default is False.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the equity.

Return

`Equity` - The new security.

Definition at line 1796 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddForex() 1/1

```
Forex QuantConnect.Algorithm.QCAlgorithm.AddForex (
String ticker,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward,
*Decimal leverage
)
```

Creates and adds a new `Forex` security to the algorithm.

Show Details

Parameters		
`String`	ticker	The currency pair.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The foreign exchange trading market, See also: `Market` . . Default value is None and looked up using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .

Return

`Forex` - The new security.

Definition at line 2152 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddFuture() 1/1

```
Future QuantConnect.Algorithm.QCAlgorithm.AddFuture (
String ticker,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward,
*Decimal leverage,
*Boolean extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Int32 contractDepthOffset
)
```

Creates and adds a new `Future` security to the algorithm.

Show Details

Parameters		
`String`	ticker	The future ticker.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The futures market, See also: `Market` . . Default is value None and looked up using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .
`*Boolean`	extendedMarketHours	*(Optional)* Use extended market hours data.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the continuous future contract.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the continuous future contract.
`*Int32`	contractDepthOffset	*(Optional)* The continuous future contract desired offset from the current front month. For example, 0 (default) will use the front month, 1 will use the back month contract.

Return

`Future` - The new security.

Definition at line 1906 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddFutureContract() 1/1

```
Future QuantConnect.Algorithm.QCAlgorithm.AddFutureContract (
 Symbol symbol,
 *Nullable<Resolution> resolution,
 *Boolean fillForward,
 *Decimal leverage,
 *Boolean extendedMarketHours
)
```

Creates and adds a new single `Future` contract to the algorithm.

Show Details

Parameters		
`Symbol`	symbol	The futures contract symbol.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .
`*Boolean`	extendedMarketHours	*(Optional)* Use extended market hours data.

Return

`Future` - The new security.

Definition at line 1942 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddFutureOption() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.AddFutureOption (
Symbol futureSymbol,
PyObject optionFilter
)
```

Creates and adds a new Future Option contract to the algorithm.

Show Details

Parameters		
Symbol	futureSymbol	The Future canonical symbol (i.e. Symbol returned from AddFuture).
PyObject	optionFilter	Filter to apply to option contracts loaded as part of the universe.

Return

Void - This method provides no return.

Definition at line 234 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA

AddFutureOption() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.AddFutureOption (
Symbol symbol,
*Func<OptionFilterUniverse, OptionFilterUniverse> optionFilter
)
```

Creates and adds a new Future Option contract to the algorithm.

Show Details

Parameters		
`Symbol`	symbol	The `Future` canonical symbol (i.e. Symbol returned from `AddFuture`).
`*Func<OptionFilterUniverse, OptionFilterUniverse>`	optionFilter	*(Optional)* Filter to apply to option contracts loaded as part of the universe.

Return

`Void` - This method provides no return.

Definition at line 1956 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddFutureOptionContract() 1/1

```
Option QuantConnect.Algorithm.QCAlgorithm.AddFutureOptionContract (
Symbol symbol,
*Nullable<Resolution> resolution,
*Boolean fillForward,
*Decimal leverage,
*Boolean extendedMarketHours
)
```

Adds a future option contract to the algorithm.

Show Details

Parameters		
`Symbol`	symbol	Option contract Symbol.
`*Nullable<Resolution>`	resolution	*(Optional)* Resolution of the option contract, i.e. the granularity of the data.
`*Boolean`	fillForward	*(Optional)* If True, this will fill in missing data points with the previous data point.
`*Decimal`	leverage	*(Optional)* The leverage to apply to the option contract.
`*Boolean`	extendedMarketHours	*(Optional)* Use extended market hours data.

Return

`Option` - Option security.

Definition at line 1977 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddIndex() 1/1

```
Index QuantConnect.Algorithm.QCAlgorithm.AddIndex (
String ticker,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward
)
```

Creates and adds a new `Index` security to the algorithm.

Show Details

Parameters		
`String`	ticker	The currency pair.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The index trading market, See also: `Market` . . Default value is None and looked up using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.

Return

`Index` - The new security.

Definition at line 2182 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddIndexOption() 1/3

```
Option QuantConnect.Algorithm.QCAlgorithm.AddIndexOption (
String ticker,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward
)
```

Creates and adds index options to the algorithm.

Show Details

Parameters		
String	ticker	The ticker of the Index Option.
*Nullable<Resolution>	resolution	*(Optional)* Resolution of the index option contracts, i.e. the granularity of the data.
*String	market	*(Optional)* Market of the index option. If no market is provided, we default to USA .
*Boolean	fillForward	*(Optional)* If True, this will fill in missing data points with the previous data point.

Return

Option - Canonical Option security.

Definition at line 1997 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddIndexOption() 2/3

```
Option QuantConnect.Algorithm.QCAlgorithm.AddIndexOption (
Symbol symbol,
*Nullable<Resolution> resolution,
*Boolean fillForward
)
```

Creates and adds index options to the algorithm.

Show Details

Parameters		
`Symbol`	symbol	The Symbol of the `Security` returned from .
`*Nullable<Resolution>`	resolution	*(Optional)* Resolution of the index option contracts, i.e. the granularity of the data.
`*Boolean`	fillForward	*(Optional)* If True, this will fill in missing data points with the previous data point.

Return

`Option` - Canonical Option security.

Definition at line 2013 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddIndexOption() 3/3

```
Option QuantConnect.Algorithm.QCAlgorithm.AddIndexOption (
Symbol symbol,
String targetOption,
*Nullable<Resolution> resolution,
*Boolean fillForward
)
```

Creates and adds index options to the algorithm.

Show Details

Parameters		
`Symbol`	symbol	The Symbol of the `Security` returned from .
`String`	targetOption	The target option ticker. This is useful when the option ticker does not match the underlying, e.g. SPX index and the SPXW weekly option. If None is provided will use underlying.
`*Nullable<Resolution>`	resolution	*(Optional)* Resolution of the index option contracts, i.e. the granularity of the data.
`*Boolean`	fillForward	*(Optional)* If True, this will fill in missing data points with the previous data point.

Return

`Option` - Canonical Option security.

Definition at line 2027 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddIndexOptionContract() 1/1

```
Option QuantConnect.Algorithm.QCAlgorithm.AddIndexOptionContract (
Symbol symbol,
*Nullable<Resolution> resolution,
*Boolean fillForward
)
```

Adds an index option contract to the algorithm.

Show Details

Parameters		
`Symbol`	symbol	Symbol of the index option contract.
`*Nullable<Resolution>`	resolution	*(Optional)* Resolution of the index option contract, i.e. the granularity of the data.
`*Boolean`	fillForward	*(Optional)* If True, this will fill in missing data points with the previous data point.

Return

`Option` - Index Option Contract.

Definition at line 2046 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddOption() 1/3

```
Option QuantConnect.Algorithm.QCAlgorithm.AddOption (
String underlying,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward,
*Decimal leverage
)
```

Creates and adds a new equity `Option` security to the algorithm.

Show Details

Parameters		
`String`	underlying	The underlying equity ticker.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The equity's market, See also: `Market` . . Default is value None and looked up using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .

Return

`Option` - The new security.

Definition at line 1812 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddOption() 2/3

```
Option QuantConnect.Algorithm.QCAlgorithm.AddOption (
Symbol underlying,
*Nullable<Resolution> resolution,
*String market,
*Boolean fillForward,
*Decimal leverage
)
```

Creates and adds a new `Option` security to the algorithm. This method can be used to add options with non-equity asset classes to the algorithm (e.g. Future Options).

Show Details

Parameters		
`Symbol`	underlying	Underlying asset Symbol to use as the option's underlying.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*String`	market	*(Optional)* The option's market, See also: `Market` . . Default value is None, but will be resolved using BrokerageModel.DefaultMarkets in `AddSecurity<T>` .
`*Boolean`	fillForward	*(Optional)* If True, data will be provided to the algorithm every Second, Minute, Hour, or Day, while the asset is open and depending on the Resolution this option was configured to use.
`*Decimal`	leverage	*(Optional)* The requested leverage for the .

Return

`Option` - The new option security instance.

Definition at line 1839 of file Algorithm/QCAlgorithm.cs.

<-- Missing documentation attribute for AddOption -->

ADDING DATA

AddOptionContract() 1/1

```
Option QuantConnect.Algorithm.QCAlgorithm.AddOptionContract (
Symbol symbol,
*Nullable<Resolution> resolution,
*Boolean fillForward,
*Decimal leverage,
*Boolean extendedMarketHours
)
```

Creates and adds a new single `Option` contract to the algorithm.

Show Details

Parameters		
`Symbol`	symbol	The option contract symbol.
`*Nullable<Resolution>`	resolution	*(Optional)* The `Resolution` of market data, Tick, Second, Minute, Hour, or Daily. Default is `Minute` .
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice. Default is True.
`*Decimal`	leverage	*(Optional)* The requested leverage for this equity. Default is set by `SecurityInitializer` .
`*Boolean`	extendedMarketHours	*(Optional)* Use extended market hours data.

Return

`Option` - The new security.

Definition at line 2066 of file Algorithm/QCAlgorithm.cs.

ALGORITHM FRAMEWORK TRADING AND ORDERS

AddRiskManagement() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.AddRiskManagement (
 IRiskManagementModel riskManagement
)
```

Adds a new risk management model.

Show Details

Parameters		
`IRiskManagementModel`	riskManagement	Model defining how risk is managed to add.

Return

`Void` - This method provides no return.

Definition at line 384 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK TRADING AND ORDERS

AddRiskManagement() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.AddRiskManagement (
PyObject riskManagement
)
```

Adds a new risk management model.

Show Details

Parameters		
PyObject	riskManagement	Model defining how risk is managed to add.

Return

Void - This method provides no return.

Definition at line 156 of file Algorithm/QCAlgorithm.Framework.Python.cs.

ADDING DATA

AddSecurity() 1/4

```
Security QuantConnect.Algorithm.QCAlgorithm.AddSecurity (
SecurityType securityType,
String ticker,
*Nullable<Resolution> resolution,
*Boolean fillForward,
*Boolean extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode
)
```

Add specified data to our data subscriptions. QuantConnect will funnel this data to the handle data routine.

Show Details

Parameters		
SecurityType	securityType	MarketType Type: Equity, Commodity, Future, FOREX or Crypto. *Options: ['Base', 'Equity', 'Option', 'Commodity', 'Forex', 'Future', 'Cfd', 'Crypto', 'FutureOption', 'Index', 'IndexOption', 'CryptoFuture']*
String	ticker	The security ticker.
*Nullable<Resolution>	resolution	*(Optional)* Resolution of the Data Required.
*Boolean	fillForward	*(Optional)* When no data available on a tradebar, return the last data that was generated.
*Boolean	extendedMarketHours	*(Optional)* Use extended market hours data.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the security.

Return

`Security` - The new `Security` object.

Definition at line 1597 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddSecurity() 2/4

```
Security QuantConnect.Algorithm.QCAlgorithm.AddSecurity (
SecurityType securityType,
String ticker,
Nullable<Resolution> resolution,
Boolean fillForward,
Decimal leverage,
Boolean extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode
)
```

Add specified data to required list. QC will funnel this data to the handle data routine.

Show Details

Parameters		
`SecurityType`	securityType	MarketType Type: Equity, Commodity, Future, FOREX or Crypto.
`String`	ticker	The security ticker.
`Nullable<Resolution>`	resolution	Resolution of the Data Required.
`Boolean`	fillForward	When no data available on a tradebar, return the last data that was generated.
`Decimal`	leverage	Custom leverage per security.
`Boolean`	extendedMarketHours	Use extended market hours data.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the security.

Return

`Security` - The new `Security` object.

Definition at line 1616 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddSecurity() 3/4

```
Security QuantConnect.Algorithm.QCAlgorithm.AddSecurity (
SecurityType securityType,
String ticker,
Nullable<Resolution> resolution,
String market,
Boolean fillForward,
Decimal leverage,
Boolean extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode
)
```

Set a required SecurityType-symbol and resolution for algorithm.

Show Details

Parameters		
`SecurityType`	securityType	MarketType Type: Equity, Commodity, Future, FOREX or Crypto.
`String`	ticker	The security ticker, e.g. AAPL.
`Nullable<Resolution>`	resolution	Resolution of the MarketType required: MarketData, Second or Minute.
`String`	market	The market the requested security belongs to, such as 'usa' or 'fxcm'.
`Boolean`	fillForward	If True, returns the last available data even if none in that timeslice.
`Decimal`	leverage	leverage for this security.
`Boolean`	extendedMarketHours	Use extended market hours data.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the security.

Return

`Security` - The new `Security` object.

Definition at line 1635 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

AddSecurity() 4/4

```
Security QuantConnect.Algorithm.QCAlgorithm.AddSecurity (
Symbol symbol,
*Nullable<Resolution> resolution,
*Boolean fillForward,
*Decimal leverage,
*Boolean extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Int32 contractDepthOffset
)
```

Set a required SecurityType-symbol and resolution for algorithm.

Show Details

Parameters		
`Symbol`	symbol	The security Symbol.
`*Nullable<Resolution>`	resolution	*(Optional)* Resolution of the MarketType required: MarketData, Second or Minute.
`*Boolean`	fillForward	*(Optional)* If True, returns the last available data even if none in that timeslice.
`*Decimal`	leverage	*(Optional)* leverage for this security.
`*Boolean`	extendedMarketHours	*(Optional)* Use extended market hours data.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the security.
`*Int32`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 (default) will use the front month, 1 will use the back month contract.

Return

`Security` - The new `Security` object.

Definition at line 1690 of file Algorithm/QCAlgorithm.cs.

CHARTING

AddSeries() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.AddSeries (
String chart,
String series,
SeriesType seriesType,
*String unit
)
```

Add a series object for charting. This is useful when initializing charts with series other than type = line. If a series exists in the chart with the same name, then it is replaced.

Show Details

Parameters		
`String`	chart	The chart name.
`String`	series	The series name.
`SeriesType`	seriesType	The type of series, i.e, Scatter. *Options: ['Line', 'Scatter', 'Candle', 'Bar', 'Flag', 'StackedArea', 'Pie', 'Treemap']*
`*String`	unit	*(Optional)* The unit of the y axis, usually $.

Return

`Void` - This method provides no return.

Definition at line 231 of file Algorithm/QCAlgorithm.Plotting.cs.

UNIVERSES

AddUniverse() 1/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
SecurityType securityType,
String name,
Resolution resolution,
String market,
UniverseSettings universeSettings,
Func<IEnumerable<T>, IEnumerable<Symbol>> selector
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
SecurityType	securityType	/
String	name	/
Resolution	resolution	/
String	market	/
UniverseSettings	universeSettings	/
Func<IEnumerable<T>, IEnumerable<Symbol>>	selector	/

Return

Universe - The new Universe object.

Definition at line 379 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 2/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
SecurityType securityType,
String name,
Resolution resolution,
String market,
UniverseSettings universeSettings,
Func<IEnumerable<T>, IEnumerable<String>> selector
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
`SecurityType`	securityType	/
`String`	name	/
`Resolution`	resolution	/
`String`	market	/
`UniverseSettings`	universeSettings	/
`Func<IEnumerable<T>, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 400 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 3/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
Func<IEnumerable<CoarseFundamental>, IEnumerable<Symbol>> selector
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
`Func<IEnumerable<CoarseFundamental>, IEnumerable<Symbol>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 418 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 4/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
Func<IEnumerable<CoarseFundamental>, IEnumerable<Symbol>> coarseSelector,
Func<IEnumerable<FineFundamental>, IEnumerable<Symbol>> fineSelector
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
Func<IEnumerable<CoarseFundamental>, IEnumerable<Symbol>>	coarseSelector	/
Func<IEnumerable<FineFundamental>, IEnumerable<Symbol>>	fineSelector	/

Return

Universe - The new Universe object.

Definition at line 430 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 5/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
Universe universe,
Func<IEnumerable<FineFundamental>, IEnumerable<Symbol>> fineSelector
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
Universe	universe	/
Func<IEnumerable<FineFundamental>, IEnumerable<Symbol>>	fineSelector	/

Return

`Universe` - The new `Universe` object.

Definition at line 444 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 6/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
Func<DateTime, IEnumerable<String>> selector
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
`String`	name	/
`Func<DateTime, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 456 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 7/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
Resolution resolution,
Func<DateTime, IEnumerable<String>> selector
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
`String`	name	/
`Resolution`	resolution	/
`Func<DateTime, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 469 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 8/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
SecurityType securityType,
String name,
Resolution resolution,
String market,
UniverseSettings universeSettings,
Func<DateTime, IEnumerable<String>> selector
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
`SecurityType`	securityType	/
`String`	name	/
`Resolution`	resolution	/
`String`	market	/
`UniverseSettings`	universeSettings	/
`Func<DateTime, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 484 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 9/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
Universe universe
)
```

Adds the universe to the algorithm.

Show Details

Parameters		
`Universe`	universe	The universe to be added.

Return

`Universe` - The new `Universe` object.

Definition at line 204 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 10/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
Func<IEnumerable<T>, IEnumerable<Symbol>> selector
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`String`	name	/
`Func<IEnumerable<T>, IEnumerable<Symbol>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 225 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 11/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
 String name,
 Func<IEnumerable<T>, IEnumerable<String>> selector
 )
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`String`	name	/
`Func<IEnumerable<T>, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 239 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 12/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
UniverseSettings universeSettings,
Func<IEnumerable<T>, IEnumerable<Symbol>> selector
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`String`	name	/
`UniverseSettings`	universeSettings	/
`Func<IEnumerable<T>, IEnumerable<Symbol>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 254 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 13/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
UniverseSettings universeSettings,
Func<IEnumerable<T>, IEnumerable<String>> selector
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`String`	name	/
`UniverseSettings`	universeSettings	/
`Func<IEnumerable<T>, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 269 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 14/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
 String name,
 Resolution resolution,
 Func<IEnumerable<T>, IEnumerable<Symbol>> selector
 )
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`String`	name	/
`Resolution`	resolution	/
`Func<IEnumerable<T>, IEnumerable<Symbol>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 284 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 15/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
Resolution resolution,
Func<IEnumerable<T>, IEnumerable<String>> selector
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`String`	name	/
`Resolution`	resolution	/
`Func<IEnumerable<T>, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 299 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 16/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
Resolution resolution,
UniverseSettings universeSettings,
Func<IEnumerable<T>, IEnumerable<Symbol>> selector
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`String`	name	/
`Resolution`	resolution	/
`UniverseSettings`	universeSettings	/
`Func<IEnumerable<T>, IEnumerable<Symbol>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 315 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 17/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
Resolution resolution,
UniverseSettings universeSettings,
Func<IEnumerable<T>, IEnumerable<String>> selector
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`String`	name	/
`Resolution`	resolution	/
`UniverseSettings`	universeSettings	/
`Func<IEnumerable<T>, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 331 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 18/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
SecurityType securityType,
String name,
Resolution resolution,
String market,
Func<IEnumerable<T>, IEnumerable<Symbol>> selector
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`SecurityType`	securityType	/
`String`	name	/
`Resolution`	resolution	/
`String`	market	/
`Func<IEnumerable<T>, IEnumerable<Symbol>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 347 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 19/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
SecurityType securityType,
String name,
Resolution resolution,
String market,
Func<IEnumerable<T>, IEnumerable<String>> selector
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
`SecurityType`	securityType	/
`String`	name	/
`Resolution`	resolution	/
`String`	market	/
`Func<IEnumerable<T>, IEnumerable<String>>`	selector	/

Return

`Universe` - The new `Universe` object.

Definition at line 363 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverse() 20/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
PyObject pyObject
)
```

Creates a new universe and adds it to the algorithm. This is for coarse fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
PyObject	pyObject	Defines an initial coarse selection.

Return

`Universe` - The new `Universe` object.

Definition at line 287 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 21/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
 PyObject pyObject,
 PyObject pyfine
)
```

Creates a new universe and adds it to the algorithm. This is for coarse and fine fundamental US Equity data and will be executed on day changes in the NewYork time zone (`NewYork` .

Show Details

Parameters		
PyObject	pyObject	Defines an initial coarse selection or a universe.
PyObject	pyfine	Defines a more detailed selection with access to more data.

Return

`Universe` - The new `Universe` object.

Definition at line 321 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 22/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
Resolution resolution,
PyObject pySelector
)
```

Creates a new universe and adds it to the algorithm. This can be used to return a list of string symbols retrieved from anywhere and will loads those symbols under the US Equity market.

Show Details

Parameters		
String	name	A unique name for this universe.
Resolution	resolution	The resolution this universe should be triggered on.
PyObject	pySelector	Function delegate that accepts a DateTime and returns a collection of string symbols.

Return

Universe - The new Universe object.

Definition at line 353 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 23/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
String name,
PyObject pySelector
)
```

Creates a new universe and adds it to the algorithm. This can be used to return a list of string symbols retrieved from anywhere and will loads those symbols under the US Equity market.

Show Details

Parameters		
String	name	A unique name for this universe.
PyObject	pySelector	Function delegate that accepts a DateTime and returns a collection of string symbols.

Return

`Universe` - The new `Universe` object.

Definition at line 366 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 24/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
 SecurityType securityType,
 String name,
 Resolution resolution,
 String market,
 UniverseSettings universeSettings,
 PyObject pySelector
)
```

Creates a new user defined universe that will fire on the requested resolution during market hours.

Show Details

Parameters		
SecurityType	securityType	The security type of the universe.
String	name	A unique name for this universe.
Resolution	resolution	The resolution this universe should be triggered on.
String	market	The market of the universe.
UniverseSettings	universeSettings	The subscription settings used for securities added from this universe.
PyObject	pySelector	Function delegate that accepts a DateTime and returns a collection of string symbols.

Return

`Universe` - The new `Universe` object.

Definition at line 382 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 25/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
PyObject T,
String name,
PyObject selector
)
```

Creates a new universe and adds it to the algorithm. This will use the default universe settings specified via the `UniverseSettings` property. This universe will use the defaults of SecurityType.Equity, Resolution.Daily, Market.USA, and UniverseSettings.

Show Details

Parameters		
`PyObject`	T	The data type.
`String`	name	A unique name for this universe.
`PyObject`	selector	Function delegate that performs selection on the universe data.

Return

`Universe` - The new `Universe` object.

Definition at line 397 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 26/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
PyObject T,
String name,
Resolution resolution,
PyObject selector
)
```

Creates a new universe and adds it to the algorithm. This will use the default universe settings specified via the `UniverseSettings` property. This universe will use the defaults of SecurityType.Equity, Market.USA and UniverseSettings.

Show Details

Parameters		
`PyObject`	T	The data type.
`String`	name	A unique name for this universe.
`Resolution`	resolution	The expected resolution of the universe data.
`PyObject`	selector	Function delegate that performs selection on the universe data.

Return

`Universe` - The new `Universe` object.

Definition at line 412 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 27/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
PyObject T,
String name,
Resolution resolution,
UniverseSettings universeSettings,
PyObject selector
)
```

Creates a new universe and adds it to the algorithm. This will use the default universe settings specified via the `UniverseSettings` property. This universe will use the defaults of SecurityType.Equity, and Market.USA.

Show Details

Parameters		
PyObject	T	The data type.
String	name	A unique name for this universe.
Resolution	resolution	The expected resolution of the universe data.
UniverseSettings	universeSettings	The settings used for securities added by this universe.
PyObject	selector	Function delegate that performs selection on the universe data.

Return

Universe - The new Universe object.

Definition at line 428 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 28/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
 PyObject T,
 String name,
 UniverseSettings universeSettings,
 PyObject selector
)
```

Creates a new universe and adds it to the algorithm. This will use the default universe settings specified via the UniverseSettings property. This universe will use the defaults of SecurityType.Equity, Resolution.Daily, and Market.USA.

Show Details

Parameters		
PyObject	T	The data type.
String	name	A unique name for this universe.
UniverseSettings	universeSettings	The settings used for securities added by this universe.
PyObject	selector	Function delegate that performs selection on the universe data.

Return

`Universe` - The new `Universe` object.

Definition at line 443 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 29/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
PyObject T,
SecurityType securityType,
String name,
Resolution resolution,
String market,
PyObject selector
)
```

Creates a new universe and adds it to the algorithm. This will use the default universe settings specified via the `UniverseSettings` property.

Show Details

Parameters		
`PyObject`	T	The data type.
`SecurityType`	securityType	The security type the universe produces.
`String`	name	A unique name for this universe.
`Resolution`	resolution	The expected resolution of the universe data.
`String`	market	The market for selected symbols.
`PyObject`	selector	Function delegate that performs selection on the universe data.

Return

`Universe` - The new `Universe` object.

Definition at line 459 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 30/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
PyObject T,
SecurityType securityType,
String name,
Resolution resolution,
String market,
UniverseSettings universeSettings,
PyObject selector
)
```

Creates a new universe and adds it to the algorithm.

Show Details

Parameters		
PyObject	T	The data type.
SecurityType	securityType	The security type the universe produces.
String	name	A unique name for this universe.
Resolution	resolution	The expected resolution of the universe data.
String	market	The market for selected symbols.
UniverseSettings	universeSettings	The subscription settings to use for newly created subscriptions.
PyObject	selector	Function delegate that performs selection on the universe data.

Return

Universe - The new Universe object.

Definition at line 475 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverse() 31/31

```
Universe QuantConnect.Algorithm.QCAlgorithm.AddUniverse (
Type dataType,
SecurityType securityType,
String name,
Resolution resolution,
String market,
UniverseSettings universeSettings,
PyObject pySelector
)
```

Creates a new universe and adds it to the algorithm.

Show Details

Parameters		
Type	dataType	The data type.
SecurityType	securityType	The security type the universe produces.
String	name	A unique name for this universe.
Resolution	resolution	The expected resolution of the universe data.
String	market	The market for selected symbols.
UniverseSettings	universeSettings	The subscription settings to use for newly created subscriptions.
PyObject	pySelector	Function delegate that performs selection on the universe data.

Return

Universe - The new Universe object.

Definition at line 491 of file Algorithm/QCAlgorithm.Python.cs.

UNIVERSES

AddUniverseOptions() 1/3

```
Void QuantConnect.Algorithm.QCAlgorithm.AddUniverseOptions (
Symbol underlyingSymbol,
Func<OptionFilterUniverse, OptionFilterUniverse> optionFilter
)
```

Adds a new universe that creates options of the security by monitoring any changes in the Universe the provided security is in. Additionally, a filter can be applied to the options generated when the universe of the security changes.

Show Details

Parameters		
`Symbol`	underlyingSymbol	Underlying Symbol to add as an option. For Futures, the option chain constructed will be per-contract, as long as a canonical Symbol is provided.
`Func<OptionFilterUniverse, OptionFilterUniverse>`	optionFilter	User-defined filter used to select the options we want out of the option chain provided.

Return

`Void` - This method provides no return.

Definition at line 502 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverseOptions() 2/3

```
Void QuantConnect.Algorithm.QCAlgorithm.AddUniverseOptions (
Universe universe,
Func<OptionFilterUniverse, OptionFilterUniverse> optionFilter
)
```

Creates a new universe selection model and adds it to the algorithm. This universe selection model will chain to the security changes of a given `Universe` selection output and create a new `OptionChainUniverse` for each of them.

Show Details

Parameters		
`Universe`	universe	The universe we want to chain an option universe selection model too.
`Func<OptionFilterUniverse, OptionFilterUniverse>`	optionFilter	The option filter universe to use.

Return

`Void` - This method provides no return.

Definition at line 541 of file Algorithm/QCAlgorithm.Universe.cs.

UNIVERSES

AddUniverseOptions() 3/3

```
Void QuantConnect.Algorithm.QCAlgorithm.AddUniverseOptions (
PyObject universe,
PyObject optionFilter
)
```

Creates a new universe selection model and adds it to the algorithm. This universe selection model will chain to the security changes of a given `Universe` selection output and create a new `OptionChainUniverse` for each of them.

Show Details

Parameters		
`PyObject`	universe	The universe we want to chain an option universe selection model too.
`PyObject`	optionFilter	The option filter universe to use.

Return

`Void` - This method provides no return.

Definition at line 518 of file Algorithm/QCAlgorithm.Python.cs.

ALGORITHM FRAMEWORK UNIVERSES

AddUniverseSelection() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.AddUniverseSelection (
IUniverseSelectionModel universeSelection
)
```

Adds a new universe selection model.

Show Details

Parameters		
IUniverseSelectionModel	universeSelection	Model defining universes for the algorithm to add.

Return

Void - This method provides no return.

Definition at line 290 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK UNIVERSES

AddUniverseSelection() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.AddUniverseSelection (
PyObject universeSelection
)
```

Adds a new universe selection model.

Show Details

Parameters		
PyObject	universeSelection	Model defining universes for the algorithm to add.

Return

Void - This method provides no return.

Definition at line 121 of file Algorithm/QCAlgorithm.Framework.Python.cs.

INDICATORS

ADDIFF() 1/1

```
AdvanceDeclineDifference QuantConnect.Algorithm.QCAlgorithm.ADDIFF (
IEnumerable<Symbol> symbols,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Func<IBaseData, TradeBar>	selector	*(Optional)* /

Return

`AdvanceDeclineDifference` - The new `AdvanceDeclineDifference` object.

Definition at line 2021 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ADOSC() 1/1

```
AccumulationDistributionOscillator QuantConnect.Algorithm.QCAlgorithm.ADOSC (
Symbol symbol,
Int32 fastPeriod,
Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new AccumulationDistributionOscillator indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose ADOSC we want.
Int32	fastPeriod	The fast moving average period.
Int32	slowPeriod	The slow moving average period.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, TradeBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AccumulationDistributionOscillator` - The AccumulationDistributionOscillator indicator for the requested symbol over the specified period.

Definition at line 83 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ADR() 1/1

```
AdvanceDeclineRatio QuantConnect.Algorithm.QCAlgorithm.ADR (
IEnumerable<Symbol> symbols,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Func<IBaseData, TradeBar>	selector	*(Optional)* /

Return

`AdvanceDeclineRatio` - The new `AdvanceDeclineRatio` object.

Definition at line 1979 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ADVR() 1/1

```
AdvanceDeclineVolumeRatio QuantConnect.Algorithm.QCAlgorithm.ADVR (
IEnumerable<Symbol> symbols,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Func<IBaseData, TradeBar>	selector	*(Optional)* /

Return

`AdvanceDeclineVolumeRatio` - The new `AdvanceDeclineVolumeRatio` object.

Definition at line 2000 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ADX() 1/1

```
AverageDirectionalIndex QuantConnect.Algorithm.QCAlgorithm.ADX (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Average Directional Index indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Average Directional Index we seek.
`Int32`	period	The period over which to compute the Average Directional Index.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AverageDirectionalIndex` - The Average Directional Index indicator for the requested symbol.

Definition at line 124 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ADXR() 1/1

```
AverageDirectionalMovementIndexRating QuantConnect.Algorithm.QCAlgorithm.ADXR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new AverageDirectionalMovementIndexRating indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ADXR we want.
`Int32`	period	The period over which to compute the ADXR.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AverageDirectionalMovementIndexRating` - The AverageDirectionalMovementIndexRating indicator for the requested symbol over the specified period.

Definition at line 161 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ALMA() 1/1

```
ArnaudLegouxMovingAverage QuantConnect.Algorithm.QCAlgorithm.ALMA (
Symbol symbol,
Int32 period,
*Int32 sigma,
*Decimal offset,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new ArnaudLegouxMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ALMA we want.
`Int32`	period	int - the number of periods to calculate the ALMA.
`*Int32`	sigma	*(Optional)* int - this parameter is responsible for the shape of the curve coefficients. .
`*Decimal`	offset	*(Optional)* decimal - This parameter allows regulating the smoothness and high sensitivity of the Moving Average. The range for this parameter is [0, 1]. .
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`ArnaudLegouxMovingAverage` - The ArnaudLegouxMovingAverage indicator for the requested symbol over the specified period.

Definition at line 185 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

AO() 1/1

```
AwesomeOscillator QuantConnect.Algorithm.QCAlgorithm.AO (
Symbol symbol,
Int32 slowPeriod,
Int32 fastPeriod,
MovingAverageType type,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Awesome Oscillator from the specified periods.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Awesome Oscillator we seek.
`Int32`	slowPeriod	The period of the slow moving average associated with the AO.
`Int32`	fastPeriod	The period of the fast moving average associated with the AO.
`MovingAverageType`	type	The type of moving average used when computing the fast and slow term. Defaults to simple moving average.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AwesomeOscillator` - The new `AwesomeOscillator` object.

Definition at line 143 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

APO() 1/1

```
AbsolutePriceOscillator QuantConnect.Algorithm.QCAlgorithm.APO (
Symbol symbol,
Int32 fastPeriod,
Int32 slowPeriod,
MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new AbsolutePriceOscillator indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose APO we want.
Int32	fastPeriod	The fast moving average period.
Int32	slowPeriod	The slow moving average period.
MovingAverageType	movingAverageType	The type of moving average to use.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AbsolutePriceOscillator` - The AbsolutePriceOscillator indicator for the requested symbol over the specified period.

Definition at line 205 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

APS() 1/1

```
AugenPriceSpike QuantConnect.Algorithm.QCAlgorithm.APS (
 Symbol symbol,
 *Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates an AugenPriceSpike indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose APS we want.
`*Int32`	period	*(Optional)* The period of the APS.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`AugenPriceSpike` - The AugenPriceSpike indicator for the given parameters.

Definition at line 277 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ARIMA() 1/1

```
AutoRegressiveIntegratedMovingAverage QuantConnect.Algorithm.QCAlgorithm.ARIMA (
Symbol symbol,
Int32 arOrder,
Int32 diffOrder,
Int32 maOrder,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new ARIMA indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose ARIMA indicator we want.
Int32	arOrder	AR order (p) -- defines the number of past values to consider in the AR component of the model.
Int32	diffOrder	Difference order (d) -- defines how many times to difference the model before fitting parameters.
Int32	maOrder	MA order (q) -- defines the number of past values to consider in the MA component of the model.
Int32	period	Size of the rolling series to fit onto.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

AutoRegressiveIntegratedMovingAverage - The ARIMA indicator for the requested symbol over the specified period.

Definition at line 104 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

AROON() 1/2

```
AroonOscillator QuantConnect.Algorithm.QCAlgorithm.AROON (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new AroonOscillator indicator which will compute the AroonUp and AroonDown (as well as the delta).

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Aroon we seek.
`Int32`	period	The look back period for computing number of periods since maximum and minimum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AroonOscillator` - An AroonOscillator configured with the specified periods.

Definition at line 223 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

AROON() 2/2

```
AroonOscillator QuantConnect.Algorithm.QCAlgorithm.AROON (
 Symbol symbol,
 Int32 upPeriod,
 Int32 downPeriod,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new AroonOscillator indicator which will compute the AroonUp and AroonDown (as well as the delta).

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Aroon we seek.
`Int32`	upPeriod	The look back period for computing number of periods since maximum.
`Int32`	downPeriod	The look back period for computing number of periods since minimum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AroonOscillator` - An AroonOscillator configured with the specified periods.

Definition at line 238 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ASI() 1/1

```
WilderAccumulativeSwingIndex QuantConnect.Algorithm.QCAlgorithm.ASI (
 Symbol symbol,
 Decimal limitMove,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates a Wilder Accumulative Swing Index (ASI) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ASI we want.
`Decimal`	limitMove	The maximum daily change in price for the ASI.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`WilderAccumulativeSwingIndex` - The WilderAccumulativeSwingIndex for the given parameters.

Definition at line 1927 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ATR() 1/1

```
AverageTrueRange QuantConnect.Algorithm.QCAlgorithm.ATR (
Symbol symbol,
Int32 period,
*MovingAverageType type,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new AverageTrueRange indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose ATR we want.
Int32	period	The smoothing period used to smooth the computed TrueRange values.
*MovingAverageType	type	*(Optional)* The type of smoothing to use.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, IBaseDataBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`AverageTrueRange` - A new AverageTrueRange indicator with the specified smoothing type and period.

Definition at line 258 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

B() 1/1

```
Beta QuantConnect.Algorithm.QCAlgorithm.B (
 Symbol target,
 Symbol reference,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates a Beta indicator for the given target symbol in relation with the reference used. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	target	The target symbol whose Beta value we want.
`Symbol`	reference	The reference symbol to compare with the target symbol.
`Int32`	period	The period of the Beta indicator.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`Beta` - The Beta indicator for the given parameters.

Definition at line 318 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

BB() 1/1

```
BollingerBands QuantConnect.Algorithm.QCAlgorithm.BB (
 Symbol symbol,
 Int32 period,
 Decimal k,
 *MovingAverageType movingAverageType,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
 )
```

Creates a new BollingerBands indicator which will compute the MiddleBand, UpperBand, LowerBand, and StandardDeviation.

Show Details

Parameters		
Symbol	symbol	The symbol whose BollingerBands we seek.
Int32	period	The period of the standard deviation and moving average (middle band).
Decimal	k	The number of standard deviations specifying the distance between the middle band and upper or lower bands.
*MovingAverageType	movingAverageType	*(Optional)* The type of moving average to be used.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

BollingerBands - A BollingerBands configured with the specified period.

Definition at line 297 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

BOP() 1/1

```
BalanceOfPower QuantConnect.Algorithm.QCAlgorithm.BOP (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Balance Of Power indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Balance Of Power we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`BalanceOfPower` - The Balance Of Power indicator for the requested symbol.

Definition at line 337 of file Algorithm/QCAlgorithm.Indicators.cs.

TRADING AND ORDERS

Buy() 1/5

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Buy (
 Symbol symbol,
 Decimal quantity
)
```

Buy Stock (Alias of Order).

Show Details

Parameters		
`Symbol`	symbol	string Symbol of the asset to trade.
`Decimal`	quantity	decimal Quantity of the asset to trade.

Return

`OrderTicket` - The order ticket instance.

Definition at line 75 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Buy() 2/5

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Buy (
Symbol symbol,
Single quantity
)
```

Buy Stock (Alias of Order).

Show Details

Parameters		
Symbol	symbol	string Symbol of the asset to trade.
Single	quantity	float Quantity of the asset to trade.

Return

`OrderTicket` - The order ticket instance.

Definition at line 88 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Buy() 3/5

```
IEnumerable<OrderTicket> QuantConnect.Algorithm.QCAlgorithm.Buy (
OptionStrategy strategy,
Int32 quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Buy Option Strategy (Alias of Order).

Show Details

Parameters		
`OptionStrategy`	strategy	Specification of the strategy to trade.
`Int32`	quantity	Quantity of the strategy to trade.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`IEnumerable<OrderTicket>` - Sequence of order tickets.

Definition at line 628 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Buy() 4/5

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Buy (
 Symbol symbol,
 Int32 quantity
)
```

Buy Stock (Alias of Order).

Show Details

Parameters		
`Symbol`	symbol	string Symbol of the asset to trade.
`Int32`	quantity	int Quantity of the asset to trade.

Return

`OrderTicket` - The order ticket instance.

Definition at line 49 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Buy() 5/5

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Buy (
 Symbol symbol,
 Double quantity
)
```

Buy Stock (Alias of Order).

Show Details

Parameters		
Symbol	symbol	string Symbol of the asset to trade.
Double	quantity	double Quantity of the asset to trade.

Return

OrderTicket - The order ticket instance.

Definition at line 62 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

CalculateOrderQuantity() 1/2

```
Decimal QuantConnect.Algorithm.QCAlgorithm.CalculateOrderQuantity (
 Symbol symbol,
 Double target
)
```

Calculate the order quantity to achieve target-percent holdings.

Show Details

Parameters		
Symbol	symbol	Security object we're asking for.
Double	target	Target percentage holdings.

Return

Decimal - Order quantity to achieve this percentage.

Definition at line 1304 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

CalculateOrderQuantity() 2/2

```
Decimal QuantConnect.Algorithm.QCAlgorithm.CalculateOrderQuantity (
 Symbol symbol,
 Decimal target
)
```

Calculate the order quantity to achieve target-percent holdings.

Show Details

Parameters		
Symbol	symbol	Security object we're asking for.
Decimal	target	Target percentage holdings, this is an unleveraged value, so if you have 2x leverage and request 100% holdings, it will utilize half of the available margin.

Return

Decimal - Order quantity to achieve this percentage.

Definition at line 1318 of file Algorithm/QCAlgorithm.Trading.cs.

INDICATORS

CC() 1/1

```
CoppockCurve QuantConnect.Algorithm.QCAlgorithm.CC (
Symbol symbol,
*Int32 shortRocPeriod,
*Int32 longRocPeriod,
*Int32 lwmaPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Initializes a new instance of the CoppockCurve" indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Coppock Curve we want.
`*Int32`	shortRocPeriod	*(Optional)* The period for the short ROC.
`*Int32`	longRocPeriod	*(Optional)* The period for the long ROC.
`*Int32`	lwmaPeriod	*(Optional)* The period for the LWMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`CoppockCurve` - The Coppock Curve indicator for the requested symbol over the specified period.

Definition at line 357 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

CCI() 1/1

```
CommodityChannelIndex QuantConnect.Algorithm.QCAlgorithm.CCI (
Symbol symbol,
Int32 period,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new CommodityChannelIndex indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose CCI we want.
`Int32`	period	The period over which to compute the CCI.
`*MovingAverageType`	movingAverageType	*(Optional)* The type of moving average to use in computing the typical price average.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`CommodityChannelIndex` - The CommodityChannelIndex indicator for the requested symbol over the specified period.

Definition at line 378 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

CMF() 1/1

```
ChaikinMoneyFlow QuantConnect.Algorithm.QCAlgorithm.CMF (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates a new ChaikinMoneyFlow indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose CMF we want.
`Int32`	period	The period over which to compute the CMF.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`ChaikinMoneyFlow` - The ChaikinMoneyFlow indicator for the requested symbol over the specified period.

Definition at line 396 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

CMO() 1/1

```
ChandeMomentumOscillator QuantConnect.Algorithm.QCAlgorithm.CMO (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new ChandeMomentumOscillator indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose CMO we want.
`Int32`	period	The period over which to compute the CMO.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`ChandeMomentumOscillator` - The ChandeMomentumOscillator indicator for the requested symbol over the specified period.

Definition at line 415 of file Algorithm/QCAlgorithm.Indicators.cs.

HANDLING DATA SECURITIES AND PORTFOLIO

CompositeFIGI() 1/2

```
Symbol QuantConnect.Algorithm.QCAlgorithm.CompositeFIGI (
String compositeFigi,
*Nullable<DateTime> tradingDate
)
```

Converts a composite FIGI identifier into a `Symbol` .

Show Details

Parameters		
`String`	compositeFigi	The composite Financial Instrument Global Identifier (FIGI) of an asset.
`*Nullable<DateTime>`	tradingDate	*(Optional)* The date that the stock being looked up is/was traded at. The date is used to create a Symbol with the ticker set to the ticker the asset traded under on the trading date. .

Return

`Symbol` - Symbol corresponding to the composite FIGI. If no Symbol with a matching composite FIGI was found, returns None.

Definition at line 2928 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA SECURITIES AND PORTFOLIO

CompositeFIGI() 2/2

```
String QuantConnect.Algorithm.QCAlgorithm.CompositeFIGI (
Symbol symbol
)
```

Converts a `Symbol` into a composite FIGI identifier.

Show Details

Parameters		
`Symbol`	symbol	The `Symbol` .

Return

`String` - Composite FIGI corresponding to the Symbol. If no matching composite FIGI is found, returns None.

Definition at line 2940 of file Algorithm/QCAlgorithm.cs.

CONSOLIDATING DATA

Consolidate() 1/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Resolution period,
PyObject handler
)
```

Registers the `handler` to receive consolidated data for the specified symbol.

Show Details

Parameters		
`Symbol`	symbol	The symbol who's data is to be consolidated.
`Resolution`	period	The consolidation period.
`PyObject`	handler	Data handler receives new consolidated data when generated.

Return

`IDataConsolidator` - A new consolidator matching the requested parameters with the handler already registered.

Definition at line 1257 of file Algorithm/QCAlgorithm.Python.cs.

CONSOLIDATING DATA

Consolidate() 2/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Resolution period,
Nullable<TickType> tickType,
PyObject handler
)
```

Registers the `handler` to receive consolidated data for the specified symbol.

Show Details

Parameters		
`Symbol`	symbol	The symbol who's data is to be consolidated.
`Resolution`	period	The consolidation period.
`Nullable<TickType>`	tickType	The tick type of subscription used as data source for consolidator. Specify None to use first subscription found.
`PyObject`	handler	Data handler receives new consolidated data when generated.

Return

`IDataConsolidator` - A new consolidator matching the requested parameters with the handler already registered.

Definition at line 1271 of file Algorithm/QCAlgorithm.Python.cs.

CONSOLIDATING DATA

Consolidate() 3/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
TimeSpan period,
PyObject handler
)
```

Registers the `handler` to receive consolidated data for the specified symbol.

Show Details

Parameters		
`Symbol`	symbol	The symbol who's data is to be consolidated.
`TimeSpan`	period	The consolidation period.
`PyObject`	handler	Data handler receives new consolidated data when generated.

Return

`IDataConsolidator` - A new consolidator matching the requested parameters with the handler already registered.

Definition at line 1284 of file Algorithm/QCAlgorithm.Python.cs.

CONSOLIDATING DATA

Consolidate() 4/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
TimeSpan period,
Nullable<TickType> tickType,
PyObject handler
)
```

Registers the `handler` to receive consolidated data for the specified symbol.

Show Details

Parameters		
Symbol	symbol	The symbol who's data is to be consolidated.
TimeSpan	period	The consolidation period.
Nullable<TickType>	tickType	The tick type of subscription used as data source for consolidator. Specify None to use first subscription found.
PyObject	handler	Data handler receives new consolidated data when generated.

Return

IDataConsolidator - A new consolidator matching the requested parameters with the handler already registered.

Definition at line 1298 of file Algorithm/QCAlgorithm.Python.cs.

CONSOLIDATING DATA

Consolidate() 5/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Func<DateTime, CalendarInfo> calendar,
PyObject handler
)
```

Registers the handler to receive consolidated data for the specified symbol.

Show Details

Parameters		
Symbol	symbol	The symbol who's data is to be consolidated.
Func<DateTime, CalendarInfo>	calendar	The consolidation calendar.
PyObject	handler	Data handler receives new consolidated data when generated.

Return

IDataConsolidator - A new consolidator matching the requested parameters with the handler already registered.

Definition at line 1324 of file Algorithm/QCAlgorithm.Python.cs.

CONSOLIDATING DATA

Consolidate() 6/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Func<DateTime, CalendarInfo> calendar,
Nullable<TickType> tickType,
PyObject handler
)
```

Registers the `handler` to receive consolidated data for the specified symbol.

Show Details

Parameters		
`Symbol`	symbol	The symbol who's data is to be consolidated.
`Func<DateTime, CalendarInfo>`	calendar	The consolidation calendar.
`Nullable<TickType>`	tickType	The tick type of subscription used as data source for consolidator. Specify None to use first subscription found.
`PyObject`	handler	Data handler receives new consolidated data when generated.

Return

`IDataConsolidator` - A new consolidator matching the requested parameters with the handler already registered.

Definition at line 1362 of file Algorithm/QCAlgorithm.Python.cs.

CONSOLIDATING DATA

Consolidate() 7/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Resolution period,
Action<TradeBar> handler
)
```

Show Details

Parameters		
Symbol	symbol	/
Resolution	period	/
Action<TradeBar>	handler	/

Return

IDataConsolidator - The new IDataConsolidator object.

Definition at line 2684 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 8/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
 Symbol symbol,
 TimeSpan period,
 Action<TradeBar> handler
 )
```

Show Details

Parameters		
Symbol	symbol	/
TimeSpan	period	/
Action<TradeBar>	handler	/

Return

IDataConsolidator - The new IDataConsolidator object.

Definition at line 2697 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 9/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Resolution period,
Action<QuoteBar> handler
)
```

Show Details

Parameters		
Symbol	symbol	/
Resolution	period	/
Action<QuoteBar>	handler	/

Return

`IDataConsolidator` - The new `IDataConsolidator` object.

Definition at line 2710 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 10/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
TimeSpan period,
Action<QuoteBar> handler
)
```

Show Details

Parameters		
Symbol	symbol	/
TimeSpan	period	/
Action<QuoteBar>	handler	/

Return

`IDataConsolidator` - The new `IDataConsolidator` object.

Definition at line 2723 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 11/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
TimeSpan period,
Action<T> handler
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`TimeSpan`	period	/
`Action<T>`	handler	/

Return

`IDataConsolidator` - The new `IDataConsolidator` object.

Definition at line 2737 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 12/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Resolution period,
Nullable<TickType> tickType,
Action<T> handler
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`Resolution`	period	/
`Nullable<TickType>`	tickType	/
`Action<T>`	handler	/

Return

`IDataConsolidator` - The new `IDataConsolidator` object.

Definition at line 2757 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 13/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
 Symbol symbol,
 TimeSpan period,
 Nullable<TickType> tickType,
 Action<T> handler
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`TimeSpan`	period	/
`Nullable<TickType>`	tickType	/
`Action<T>`	handler	/

Return

`IDataConsolidator` - The new `IDataConsolidator` object.

Definition at line 2773 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 14/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Func<DateTime, CalendarInfo> calendar,
Action<QuoteBar> handler
)
```

Show Details

Parameters		
Symbol	symbol	/
Func<DateTime, CalendarInfo>	calendar	/
Action<QuoteBar>	handler	/

Return

IDataConsolidator - The new IDataConsolidator object.

Definition at line 2794 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 15/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Func<DateTime, CalendarInfo> calendar,
Action<TradeBar> handler
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`Func<DateTime, CalendarInfo>`	calendar	/
`Action<TradeBar>`	handler	/

Return

`IDataConsolidator` - The new `IDataConsolidator` object.

Definition at line 2807 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 16/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Func<DateTime, CalendarInfo> calendar,
Action<T> handler
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`Func<DateTime, CalendarInfo>`	calendar	/
`Action<T>`	handler	/

Return

`IDataConsolidator` - The new `IDataConsolidator` object.

Definition at line 2821 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

Consolidate() 17/17

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.Consolidate (
Symbol symbol,
Func<DateTime, CalendarInfo> calendar,
Nullable<TickType> tickType,
Action<T> handler
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`Func<DateTime, CalendarInfo>`	calendar	/
`Nullable<TickType>`	tickType	/
`Action<T>`	handler	/

Return

`IDataConsolidator` - The new `IDataConsolidator` object.

Definition at line 2841 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA

CreateConsolidator() 1/1

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.CreateConsolidator (
TimeSpan period,
Type consolidatorInputType,
*Nullable<TickType> tickType
)
```

Creates a new consolidator for the specified period, generating the requested output type.

Show Details

Parameters		
TimeSpan	period	The consolidation period.
Type	consolidatorInputType	The desired input type of the consolidator, such as TradeBar or QuoteBar.
*Nullable<TickType>	tickType	*(Optional)* Trade or Quote. Optional, defaults to trade.

Return

IDataConsolidator - A new consolidator matching the requested parameters.

Definition at line 2607 of file Algorithm/QCAlgorithm.Indicators.cs.

HANDLING DATA SECURITIES AND PORTFOLIO

CUSIP() 1/2

```
Symbol QuantConnect.Algorithm.QCAlgorithm.CUSIP (
 String cusip,
 *Nullable<DateTime> tradingDate
)
```

Converts a CUSIP identifier into a Symbol .

Show Details

Parameters		
String	cusip	The CUSIP number of an asset.
*Nullable<DateTime>	tradingDate	*(Optional)* The date that the stock being looked up is/was traded at. The date is used to create a Symbol with the ticker set to the ticker the asset traded under on the trading date. .

Return

Symbol - Symbol corresponding to the CUSIP. If no Symbol with a matching CUSIP was found, returns None.

Definition at line 2956 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA SECURITIES AND PORTFOLIO

CUSIP() 2/2

```
String QuantConnect.Algorithm.QCAlgorithm.CUSIP (
Symbol symbol
)
```

Converts a `Symbol` into a CUSIP identifier.

Show Details

Parameters		
`Symbol`	symbol	The `Symbol` .

Return

`String` - CUSIP corresponding to the Symbol. If no matching CUSIP is found, returns None.

Definition at line 2968 of file Algorithm/QCAlgorithm.cs.

INDICATORS

DCH() 1/2

```
DonchianChannel QuantConnect.Algorithm.QCAlgorithm.DCH (
Symbol symbol,
Int32 upperPeriod,
Int32 lowerPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Donchian Channel indicator which will compute the Upper Band and Lower Band. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose Donchian Channel we seek.
Int32	upperPeriod	The period over which to compute the upper Donchian Channel.
Int32	lowerPeriod	The period over which to compute the lower Donchian Channel.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, IBaseDataBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

DonchianChannel - The Donchian Channel indicator for the requested symbol.

Definition at line 454 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

DCH() 2/2

```
DonchianChannel QuantConnect.Algorithm.QCAlgorithm.DCH (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Overload shorthand to create a new symmetric Donchian Channel indicator which has the upper and lower channels set to the same period length.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Donchian Channel we seek.
`Int32`	period	The period over which to compute the Donchian Channel.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`DonchianChannel` - The Donchian Channel indicator for the requested symbol.

Definition at line 473 of file Algorithm/QCAlgorithm.Indicators.cs.

LOGGING

Debug() 1/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Debug (
 PyObject message
)
```

Send a debug message to the web console:.

Show Details

Parameters		
`PyObject`	message	Message to send to debug console.

Return

`Void` - This method provides no return.

Definition at line 1210 of file Algorithm/QCAlgorithm.Python.cs.

LOGGING

Debug() 2/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Debug (
String message
)
```

Send a debug message to the web console:.

Show Details

Parameters		
String	message	Message to send to debug console.

Return

Void - This method provides no return.

Definition at line 2453 of file Algorithm/QCAlgorithm.cs.

LOGGING

Debug() 3/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Debug (
Int32 message
)
```

Send a debug message to the web console:.

Show Details

Parameters		
Int32	message	Message to send to debug console.

Return

Void - This method provides no return.

Definition at line 2467 of file Algorithm/QCAlgorithm.cs.

LOGGING

Debug() 4/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Debug (
Double message
)
```

Send a debug message to the web console:.

Show Details

Parameters		
Double	message	Message to send to debug console.

Return

Void - This method provides no return.

Definition at line 2479 of file Algorithm/QCAlgorithm.cs.

LOGGING

Debug() 5/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Debug (
Decimal message
)
```

Send a debug message to the web console:.

Show Details

Parameters		
Decimal	message	Message to send to debug console.

Return

Void - This method provides no return.

Definition at line 2491 of file Algorithm/QCAlgorithm.cs.

INDICATORS

DEM() 1/1

```
DeMarkerIndicator QuantConnect.Algorithm.QCAlgorithm.DEM (
Symbol symbol,
Int32 period,
MovingAverageType type,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new DeMarker Indicator (DEM), an oscillator-type indicator measuring changes in terms of an asset's High and Low tradebar values.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose DEM we seek.
`Int32`	period	The period of the moving average implemented.
`MovingAverageType`	type	Specifies the type of moving average to be used.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`DeMarkerIndicator` - The DeMarker indicator for the requested symbol.

Definition at line 435 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

DEMA() 1/1

```
DoubleExponentialMovingAverage QuantConnect.Algorithm.QCAlgorithm.DEMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new DoubleExponentialMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose DEMA we want.
`Int32`	period	The period over which to compute the DEMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`DoubleExponentialMovingAverage` - The DoubleExponentialMovingAverage indicator for the requested symbol over the specified period.

Definition at line 487 of file Algorithm/QCAlgorithm.Indicators.cs.

ADDING DATA | MACHINE LEARNING

Download() 1/5

```
String QuantConnect.Algorithm.QCAlgorithm.Download (
String address,
PyObject headers
)
```

Downloads the requested resource as a `String` . The resource to download is specified as a `String` containing the URI.

Show Details

Parameters		
String	address	A string containing the URI to download.
PyObject	headers	Defines header values to add to the request.

Return

String - The requested resource as a.

Definition at line 1160 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA MACHINE LEARNING

Download() 2/5

```
String QuantConnect.Algorithm.QCAlgorithm.Download (
 String address,
 PyObject headers,
 String userName,
 String password
)
```

Downloads the requested resource as a String . The resource to download is specified as a String containing the URI.

Show Details

Parameters		
String	address	A string containing the URI to download.
PyObject	headers	Defines header values to add to the request.
String	userName	The user name associated with the credentials.
String	password	The password for the user name associated with the credentials.

Return

String - The requested resource as a.

Definition at line 1173 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA MACHINE LEARNING

Download() 3/5

```
String QuantConnect.Algorithm.QCAlgorithm.Download (
 String address
)
```

Downloads the requested resource as a `String` . The resource to download is specified as a `String` containing the URI.

Show Details

Parameters		
`String`	address	A string containing the URI to download.

Return

`String` - The requested resource as a.

Definition at line 2729 of file Algorithm/QCAlgorithm.cs.

ADDING DATA MACHINE LEARNING

Download() 4/5

```
String QuantConnect.Algorithm.QCAlgorithm.Download (
 String address,
 IEnumerable<KeyValuePair<String, String>> headers
)
```

Show Details

Parameters		
`String`	address	/
`IEnumerable<KeyValuePair<String, String>>`	headers	/

Return

`String` - The new `String` object.

Definition at line 2740 of file Algorithm/QCAlgorithm.cs.

ADDING DATA MACHINE LEARNING

Download() 5/5

```
String QuantConnect.Algorithm.QCAlgorithm.Download (
String address,
IEnumerable<KeyValuePair<String, String>> headers,
String userName,
String password
)
```

Show Details

Parameters		
`String`	address	/
`IEnumerable<KeyValuePair<String, String>>`	headers	/
`String`	userName	/
`String`	password	/

Return

`String` - The new `String` object.

Definition at line 2753 of file Algorithm/QCAlgorithm.cs.

INDICATORS

DPO() 1/1

```
DetrendedPriceOscillator QuantConnect.Algorithm.QCAlgorithm.DPO (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new DetrendedPriceOscillator" indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose DPO we want.
`Int32`	period	The period over which to compute the DPO.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`DetrendedPriceOscillator` - A new registered DetrendedPriceOscillator indicator for the requested symbol over the specified period.

Definition at line 505 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

EMA() 1/2

```
ExponentialMovingAverage QuantConnect.Algorithm.QCAlgorithm.EMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates an ExponentialMovingAverage indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose EMA we want.
`Int32`	period	The period of the EMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`ExponentialMovingAverage` - The ExponentialMovingAverage for the given parameters.

Definition at line 524 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

EMA() 2/2

```
ExponentialMovingAverage QuantConnect.Algorithm.QCAlgorithm.EMA (
 Symbol symbol,
 Int32 period,
 Decimal smoothingFactor,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates an ExponentialMovingAverage indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose EMA we want.
`Int32`	period	The period of the EMA.
`Decimal`	smoothingFactor	The percentage of data from the previous value to be carried into the next value.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`ExponentialMovingAverage` - The ExponentialMovingAverage for the given parameters.

Definition at line 540 of file Algorithm/QCAlgorithm.Indicators.cs.

ALGORITHM FRAMEWORK

EmitInsights() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.EmitInsights (
Insight> insights
)
```

Manually emit insights from an algorithm. This is typically invoked before calls to submit orders in algorithms written against QCAlgorithm that have been ported into the algorithm framework.

Show Details

Parameters		
`Insight>`	insights	The array of insights to be emitted.

Return

`Void` - This method provides no return.

Definition at line 412 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK

EmitInsights() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.EmitInsights (
Insight insight
)
```

Manually emit insights from an algorithm. This is typically invoked before calls to submit orders in algorithms written against QCAlgorithm that have been ported into the algorithm framework.

Show Details

Parameters		
Insight	insight	The insight to be emitted.

Return

Void - This method provides no return.

Definition at line 436 of file Algorithm/QCAlgorithm.Framework.cs.

INDICATORS

EMV() 1/1

```
EaseOfMovementValue QuantConnect.Algorithm.QCAlgorithm.EMV (
Symbol symbol,
*Int32 period,
*Int32 scale,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an EaseOfMovementValue indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose EMV we want.
`*Int32`	period	*(Optional)* The period of the EMV.
`*Int32`	scale	*(Optional)* The length of the outputed value.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`EaseOfMovementValue` - The EaseOfMovementValue indicator for the given parameters.

Definition at line 560 of file Algorithm/QCAlgorithm.Indicators.cs.

LOGGING

Error() 1/6

```
Void QuantConnect.Algorithm.QCAlgorithm.Error (
 PyObject message
)
```

Send a string error message to the Console.

Show Details

Parameters		
`PyObject`	message	Message to display in errors grid.

Return

`Void` - This method provides no return.

Definition at line 1222 of file Algorithm/QCAlgorithm.Python.cs.

LOGGING

Error() 2/6

```
Void QuantConnect.Algorithm.QCAlgorithm.Error (
 String message
)
```

Send a string error message to the Console.

Show Details

Parameters		
String	message	Message to display in errors grid.

Return

Void - This method provides no return.

Definition at line 2552 of file Algorithm/QCAlgorithm.cs.

LOGGING

Error() 3/6

```
Void QuantConnect.Algorithm.QCAlgorithm.Error (
 Int32 message
)
```

Send a int error message to the Console.

Show Details

Parameters		
Int32	message	Message to display in errors grid.

Return

Void - This method provides no return.

Definition at line 2566 of file Algorithm/QCAlgorithm.cs.

LOGGING

Error() 4/6

```
Void QuantConnect.Algorithm.QCAlgorithm.Error (
Double message
)
```

Send a double error message to the Console.

Show Details

Parameters		
Double	message	Message to display in errors grid.

Return

Void - This method provides no return.

Definition at line 2578 of file Algorithm/QCAlgorithm.cs.

LOGGING

Error() 5/6

```
Void QuantConnect.Algorithm.QCAlgorithm.Error (
Decimal message
)
```

Send a decimal error message to the Console.

Show Details

Parameters		
Decimal	message	Message to display in errors grid.

Return

`Void` - This method provides no return.

Definition at line 2590 of file Algorithm/QCAlgorithm.cs.

LOGGING

Error() 6/6

```
Void QuantConnect.Algorithm.QCAlgorithm.Error (
Exception error
)
```

Send a string error message to the Console.

Show Details

Parameters		
`Exception`	error	Exception object captured from a try catch loop.

Return

`Void` - This method provides no return.

Definition at line 2602 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS

ExerciseOption() 1/1

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.ExerciseOption (
Symbol optionSymbol,
Int32 quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Send an exercise order to the transaction handler.

Show Details

Parameters		
`Symbol`	optionSymbol	String symbol for the option position.
`Int32`	quantity	Quantity of options contracts.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 589 of file Algorithm/QCAlgorithm.Trading.cs.

INDICATORS

FilteredIdentity() 1/6

```
FilteredIdentity QuantConnect.Algorithm.QCAlgorithm.FilteredIdentity (
 Symbol symbol,
 *PyObject selector,
 *PyObject filter,
 *String fieldName
)
```

Creates a new FilteredIdentity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`*PyObject`	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
`*PyObject`	filter	*(Optional)* Filters the IBaseData send into the indicator, if None defaults to True (x => True) which means no filter.
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`FilteredIdentity` - A new FilteredIdentity indicator for the specified symbol and selector.

Definition at line 791 of file Algorithm/QCAlgorithm.Python.cs.

INDICATORS

FilteredIdentity() 2/6

```
FilteredIdentity QuantConnect.Algorithm.QCAlgorithm.FilteredIdentity (
 Symbol symbol,
 Resolution resolution,
 *PyObject selector,
 *PyObject filter,
 *String fieldName
)
```

Creates a new FilteredIdentity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`Resolution`	resolution	The desired resolution of the data.
`*PyObject`	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
`*PyObject`	filter	*(Optional)* Filters the IBaseData send into the indicator, if None defaults to True (x => True) which means no filter.
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`FilteredIdentity` - A new FilteredIdentity indicator for the specified symbol and selector.

Definition at line 808 of file Algorithm/QCAlgorithm.Python.cs.

INDICATORS

FilteredIdentity() 3/6

```
FilteredIdentity QuantConnect.Algorithm.QCAlgorithm.FilteredIdentity (
 Symbol symbol,
 TimeSpan resolution,
 *PyObject selector,
 *PyObject filter,
 *String fieldName
)
```

Creates a new FilteredIdentity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose values we want as an indicator.
TimeSpan	resolution	The desired resolution of the data.
*PyObject	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
*PyObject	filter	*(Optional)* Filters the IBaseData send into the indicator, if None defaults to True (x => True) which means no filter.
*String	fieldName	*(Optional)* The name of the field being selected.

Return

FilteredIdentity - A new FilteredIdentity indicator for the specified symbol and selector.

Definition at line 829 of file Algorithm/QCAlgorithm.Python.cs.

INDICATORS

FilteredIdentity() 4/6

```
FilteredIdentity QuantConnect.Algorithm.QCAlgorithm.FilteredIdentity (
 Symbol symbol,
 *Func<IBaseData, IBaseDataBar> selector,
 *Func<IBaseData, Boolean> filter,
 *String fieldName
)
```

Creates a new FilteredIdentity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.
`*Func<IBaseData, Boolean>`	filter	*(Optional)* Filters the IBaseData send into the indicator, if None defaults to True (x => True) which means no filter.
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`FilteredIdentity` - A new FilteredIdentity indicator for the specified symbol and selector.

Definition at line 579 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

FilteredIdentity() 5/6

```
FilteredIdentity QuantConnect.Algorithm.QCAlgorithm.FilteredIdentity (
 Symbol symbol,
 Resolution resolution,
 *Func<IBaseData, IBaseDataBar> selector,
 *Func<IBaseData, Boolean> filter,
 *String fieldName
)
```

Creates a new FilteredIdentity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`Resolution`	resolution	The desired resolution of the data.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.
`*Func<IBaseData, Boolean>`	filter	*(Optional)* Filters the IBaseData send into the indicator, if None defaults to True (x => True) which means no filter.
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`FilteredIdentity` - A new FilteredIdentity indicator for the specified symbol and selector.

Definition at line 596 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

FilteredIdentity() 6/6

```
FilteredIdentity QuantConnect.Algorithm.QCAlgorithm.FilteredIdentity (
 Symbol symbol,
 TimeSpan resolution,
 *Func<IBaseData, IBaseDataBar> selector,
 *Func<IBaseData, Boolean> filter,
 *String fieldName
)
```

Creates a new FilteredIdentity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose values we want as an indicator.
TimeSpan	resolution	The desired resolution of the data.
*Func<IBaseData, IBaseDataBar>	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
*Func<IBaseData, Boolean>	filter	*(Optional)* Filters the IBaseData send into the indicator, if None defaults to True (x => True) which means no filter.
*String	fieldName	*(Optional)* The name of the field being selected.

Return

`FilteredIdentity` - A new FilteredIdentity indicator for the specified symbol and selector.

Definition at line 615 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

FISH() 1/1

```
FisherTransform QuantConnect.Algorithm.QCAlgorithm.FISH (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates an FisherTransform indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose FisherTransform we want.
`Int32`	period	The period of the FisherTransform.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`FisherTransform` - The FisherTransform for the given parameters.

Definition at line 633 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

FRAMA() 1/1

```
FractalAdaptiveMovingAverage QuantConnect.Algorithm.QCAlgorithm.FRAMA (
Symbol symbol,
Int32 period,
*Int32 longPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates an FractalAdaptiveMovingAverage (FRAMA) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose FRAMA we want.
`Int32`	period	The period of the FRAMA.
`*Int32`	longPeriod	*(Optional)* The long period of the FRAMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`FractalAdaptiveMovingAverage` - The FRAMA for the given parameters.

Definition at line 653 of file Algorithm/QCAlgorithm.Indicators.cs.

ALGORITHM FRAMEWORK

FrameworkPostInitialize() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.FrameworkPostInitialize (
)
```

Called by setup handlers after Initialize and allows the algorithm a chance to organize the data gather in the Initialize method.

Show Details

This method requires no argument input.

Return

`Void` - This method provides no return.

Definition at line 84 of file Algorithm/QCAlgorithm.Framework.cs.

ADDING DATA HISTORICAL DATA

GetLastKnownPrices() 1/2

```
IEnumerable<BaseData> QuantConnect.Algorithm.QCAlgorithm.GetLastKnownPrices (
Security security
)
```

Yields data to warmup a security for all it's subscribed data types.

Show Details

Parameters		
Security	security	Security object for which to retrieve historical data.

Return

IEnumerable<BaseData> - Securities historical data.

Definition at line 629 of file Algorithm/QCAlgorithm.History.cs.

ADDING DATA HISTORICAL DATA

GetLastKnownPrices() 2/2

```
IEnumerable<BaseData> QuantConnect.Algorithm.QCAlgorithm.GetLastKnownPrices (
Symbol symbol
)
```

Yields data to warmup a security for all it's subscribed data types.

Show Details

Parameters		
Symbol	symbol	The symbol we want to get seed data for.

Return

IEnumerable<BaseData> - Securities historical data.

Definition at line 641 of file Algorithm/QCAlgorithm.History.cs.

PARAMETER AND OPTIMIZATION

GetParameters() 1/1

```
IReadOnlyDictionary<String, String> QuantConnect.Algorithm.QCAlgorithm.GetParameters (

)
```

Gets a read-only dictionary with all current parameters.

Show Details

This method requires no argument input.

Return

`IReadOnlyDictionary<String, String>` - The new `IReadOnlyDictionary<String, String>` object.

Definition at line 730 of file Algorithm/QCAlgorithm.cs.

INDICATORS

HeikinAshi() 1/1

```
HeikinAshi QuantConnect.Algorithm.QCAlgorithm.HeikinAshi (
 Symbol symbol,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates a new Heikin-Ashi indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Heikin-Ashi we want.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`HeikinAshi` - The Heikin-Ashi indicator for the requested symbol over the specified period.

Definition at line 670 of file Algorithm/QCAlgorithm.Indicators.cs.

HISTORICAL DATA

History() 1/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
 PyObject tickers,
 Int32 periods,
 *Nullable<Resolution> resolution,
 *Nullable<Boolean> fillForward,
 *Nullable<Boolean> extendedMarketHours,
 *Nullable<DataMappingMode> dataMappingMode,
 *Nullable<DataNormalizationMode> dataNormalizationMode,
 *Nullable<Int32> contractDepthOffset
 )
```

Gets the historical data for the specified symbol. The exact number of bars will be returned. The symbol must exist in the Securities collection.

Show Details

Parameters		
PyObject	tickers	The symbols to retrieve historical data for.
Int32	periods	The number of bars to request.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.
*Nullable<Boolean>	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
*Nullable<Boolean>	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
*Nullable<Int32>	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

PyObject - A python dictionary with pandas DataFrame containing the requested historical data.

Definition at line 854 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 2/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
 PyObject tickers,
 TimeSpan span,
 *Nullable<Resolution> resolution,
 *Nullable<Boolean> fillForward,
 *Nullable<Boolean> extendedMarketHours,
 *Nullable<DataMappingMode> dataMappingMode,
 *Nullable<DataNormalizationMode> dataNormalizationMode,
 *Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbols over the requested span. The symbols must exist in the Securities collection.

Show Details

Parameters		
PyObject	tickers	The symbols to retrieve historical data for.
TimeSpan	span	The span over which to retrieve recent historical data.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.
*Nullable<Boolean>	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
*Nullable<Boolean>	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
*Nullable<Int32>	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

PyObject - A python dictionary with pandas DataFrame containing the requested historical data.

Definition at line 878 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 3/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
PyObject tickers,
DateTime start,
DateTime end,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbols between the specified dates. The symbols must exist in the Securities collection.

Show Details

Parameters		
PyObject	tickers	The symbols to retrieve historical data for.
DateTime	start	The start time in the algorithm's time zone.
DateTime	end	The end time in the algorithm's time zone.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.
*Nullable<Boolean>	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
*Nullable<Boolean>	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
*Nullable<Int32>	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

PyObject - A python dictionary with a pandas DataFrame containing the requested historical data.

Definition at line 902 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 4/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
PyObject tickers,
DateTime start,
DateTime end,
*Nullable<Resolution> resolution
)
```

Gets the historical data for the specified symbol between the specified dates. The symbol must exist in the Securities collection.

Show Details

Parameters		
PyObject	tickers	The symbols to retrieve historical data for.
DateTime	start	The start time in the algorithm's time zone.
DateTime	end	The end time in the algorithm's time zone.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.

Return

PyObject - A python dictionary with pandas DataFrame containing the requested historical data.

Definition at line 920 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 5/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
 PyObject type,
 PyObject tickers,
 DateTime start,
 DateTime end,
 *Nullable<Resolution> resolution,
 *Nullable<Boolean> fillForward,
 *Nullable<Boolean> extendedMarketHours,
 *Nullable<DataMappingMode> dataMappingMode,
 *Nullable<DataNormalizationMode> dataNormalizationMode,
 *Nullable<Int32> contractDepthOffset
 )
```

Gets the historical data for the specified symbols between the specified dates. The symbols must exist in the Securities collection.

Show Details

Parameters		
PyObject	type	The data type of the symbols.
PyObject	tickers	The symbols to retrieve historical data for.
DateTime	start	The start time in the algorithm's time zone.
DateTime	end	The end time in the algorithm's time zone.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.
*Nullable<Boolean>	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
*Nullable<Boolean>	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
*Nullable<Int32>	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

PyObject - pandas.DataFrame containing the requested historical data.

Definition at line 942 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 6/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
 PyObject type,
 PyObject tickers,
 Int32 periods,
 *Nullable<Resolution> resolution,
 *Nullable<Boolean> fillForward,
 *Nullable<Boolean> extendedMarketHours,
 *Nullable<DataMappingMode> dataMappingMode,
 *Nullable<DataNormalizationMode> dataNormalizationMode,
 *Nullable<Int32> contractDepthOffset
 )
```

Gets the historical data for the specified symbols. The exact number of bars will be returned for each symbol. This may result in some data start earlier/later than others due to when various exchanges are open. The symbols must exist in the Securities collection.

Show Details

Parameters		
`PyObject`	type	The data type of the symbols.
`PyObject`	tickers	The symbols to retrieve historical data for.
`Int32`	periods	The number of bars to request.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`PyObject` - pandas.DataFrame containing the requested historical data.

Definition at line 970 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 7/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
 PyObject type,
 PyObject tickers,
 TimeSpan span,
 *Nullable<Resolution> resolution,
 *Nullable<Boolean> fillForward,
 *Nullable<Boolean> extendedMarketHours,
 *Nullable<DataMappingMode> dataMappingMode,
 *Nullable<DataNormalizationMode> dataNormalizationMode,
 *Nullable<Int32> contractDepthOffset
 )
```

Gets the historical data for the specified symbols over the requested span. The symbols must exist in the Securities collection.

Show Details

Parameters		
PyObject	type	The data type of the symbols.
PyObject	tickers	The symbols to retrieve historical data for.
TimeSpan	span	The span over which to retrieve recent historical data.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.
*Nullable<Boolean>	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
*Nullable<Boolean>	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
*Nullable<Int32>	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

PyObject - pandas.DataFrame containing the requested historical data.

Definition at line 1000 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 8/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
PyObject type,
Symbol symbol,
DateTime start,
DateTime end,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbols between the specified dates. The symbols must exist in the Securities collection.

Show Details

Parameters		
`PyObject`	type	The data type of the symbols.
`Symbol`	symbol	The symbol to retrieve historical data for.
`DateTime`	start	The start time in the algorithm's time zone.
`DateTime`	end	The end time in the algorithm's time zone.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`PyObject` - pandas.DataFrame containing the requested historical data.

Definition at line 1024 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 9/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
PyObject type,
Symbol symbol,
Int32 periods,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbols. The exact number of bars will be returned for each symbol. This may result in some data start earlier/later than others due to when various exchanges are open. The symbols must exist in the Securities collection.

Show Details

Parameters		
PyObject	type	The data type of the symbols.
Symbol	symbol	The symbol to retrieve historical data for.
Int32	periods	The number of bars to request.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.
*Nullable<Boolean>	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
*Nullable<Boolean>	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
*Nullable<Int32>	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

PyObject - pandas.DataFrame containing the requested historical data.

Definition at line 1057 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 10/27

```
PyObject QuantConnect.Algorithm.QCAlgorithm.History (
 PyObject type,
 Symbol symbol,
 TimeSpan span,
 *Nullable<Resolution> resolution,
 *Nullable<Boolean> fillForward,
 *Nullable<Boolean> extendedMarketHours,
 *Nullable<DataMappingMode> dataMappingMode,
 *Nullable<DataNormalizationMode> dataNormalizationMode,
 *Nullable<Int32> contractDepthOffset
 )
```

Gets the historical data for the specified symbols over the requested span. The symbols must exist in the

Securities collection.

Show Details

Parameters		
PyObject	type	The data type of the symbols.
Symbol	symbol	The symbol to retrieve historical data for.
TimeSpan	span	The span over which to retrieve recent historical data.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.
*Nullable<Boolean>	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
*Nullable<Boolean>	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
*Nullable<Int32>	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

PyObject - pandas.DataFrame containing the requested historical data.

Definition at line 1087 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA

History() 11/27

```
IEnumerable<Slice> QuantConnect.Algorithm.QCAlgorithm.History (
TimeSpan span,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Get the history for all configured securities over the requested span. This will use the resolution and other subscription settings for each security. The symbols must exist in the Securities collection.

Show Details

Parameters		
`TimeSpan`	span	The span over which to request data. This is a calendar span, so take into consideration weekends and such.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`IEnumerable<Slice>` - An enumerable of slice containing data over the most recent span for all configured securities.

Definition at line 231 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 12/27

```
IEnumerable<Slice> QuantConnect.Algorithm.QCAlgorithm.History (
Int32 periods,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Get the history for all configured securities over the requested span. This will use the resolution and other subscription settings for each security. The symbols must exist in the Securities collection.

Show Details

Parameters		
`Int32`	periods	The number of bars to request.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`IEnumerable<Slice>` - An enumerable of slice containing data over the most recent span for all configured securities.

Definition at line 253 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 13/27

```
IEnumerable<DataDictionary<T>> QuantConnect.Algorithm.QCAlgorithm.History (
TimeSpan span,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Get the history for all configured securities over the requested span. This will use the resolution and other subscription settings for each security. The symbols must exist in the Securities collection.

Show Details

Parameters		
TimeSpan	span	The span over which to request data. This is a calendar span, so take into consideration weekends and such.
*Nullable<Resolution>	resolution	*(Optional)* The resolution to request.
*Nullable<Boolean>	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
*Nullable<Boolean>	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
*Nullable<Int32>	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

IEnumerable<DataDictionary<T>> - An enumerable of slice containing data over the most recent span for all configured securities.

Definition at line 275 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 14/27

```
IEnumerable<DataDictionary<T>> QuantConnect.Algorithm.QCAlgorithm.History (
IEnumerable<Symbol> symbols,
TimeSpan span,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol over the request span. The symbol must exist in the Securities collection.

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
TimeSpan	span	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Nullable<Boolean>	fillForward	*(Optional)* /
*Nullable<Boolean>	extendedMarketHours	*(Optional)* /
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* /
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* /
*Nullable<Int32>	contractDepthOffset	*(Optional)* /

Return

`IEnumerable<DataDictionary<T>>` - The new `IEnumerable<DataDictionary<T>>` object.

Definition at line 300 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 15/27

```
IEnumerable<DataDictionary<T>> QuantConnect.Algorithm.QCAlgorithm.History (
IEnumerable<Symbol> symbols,
Int32 periods,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol over the request span. The symbol must exist in the Securities collection.

Show Details

Parameters		
`IEnumerable<Symbol>`	symbols	/
`Int32`	periods	/
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Nullable<Boolean>`	fillForward	*(Optional)* /
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* /
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* /
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* /
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* /

Return

`IEnumerable<DataDictionary<T>>` - The new `IEnumerable<DataDictionary<T>>` object.

Definition at line 326 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 16/27

```
IEnumerable<DataDictionary<T>> QuantConnect.Algorithm.QCAlgorithm.History (
IEnumerable<Symbol> symbols,
DateTime start,
DateTime end,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol over the request span. The symbol must exist in the Securities collection.

Show Details

Parameters		
`IEnumerable<Symbol>`	symbols	/
`DateTime`	start	/
`DateTime`	end	/
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Nullable<Boolean>`	fillForward	*(Optional)* /
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* /
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* /
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* /
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* /

Return

`IEnumerable<DataDictionary<T>>` - The new `IEnumerable<DataDictionary<T>>` object.

Definition at line 353 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 17/27

```
IEnumerable<T> QuantConnect.Algorithm.QCAlgorithm.History (
Symbol symbol,
TimeSpan span,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol over the request span. The symbol must exist in the Securities collection.

Show Details

Parameters		
`Symbol`	symbol	The symbol to retrieve historical data for.
`TimeSpan`	span	The span over which to retrieve recent historical data.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`IEnumerable<T>` - An enumerable of slice containing the requested historical data.

Definition at line 378 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 18/27

```
IEnumerable<TradeBar> QuantConnect.Algorithm.QCAlgorithm.History (
Symbol symbol,
Int32 periods,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol. The exact number of bars will be returned. The symbol must exist in the Securities collection.

Show Details

Parameters		
`Symbol`	symbol	The symbol to retrieve historical data for.
`Int32`	periods	The number of bars to request.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`IEnumerable<TradeBar>` - An enumerable of slice containing the requested historical data.

Definition at line 402 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 19/27

```
IEnumerable<T> QuantConnect.Algorithm.QCAlgorithm.History (
Symbol symbol,
Int32 periods,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol. The exact number of bars will be returned. The symbol must exist in the Securities collection.

Show Details

Parameters		
`Symbol`	symbol	The symbol to retrieve historical data for.
`Int32`	periods	The number of bars to request.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`IEnumerable<T>` - An enumerable of slice containing the requested historical data.

Definition at line 434 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 20/27

```
IEnumerable<T> QuantConnect.Algorithm.QCAlgorithm.History (
Symbol symbol,
DateTime start,
DateTime end,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol over the request span. The symbol must exist in the Securities collection.

Show Details

Parameters		
`Symbol`	symbol	The symbol to retrieve historical data for.
`DateTime`	start	The start time in the algorithm's time zone.
`DateTime`	end	The end time in the algorithm's time zone.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`IEnumerable<T>` - An enumerable of slice containing the requested historical data.

Definition at line 461 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 21/27

```
IEnumerable<TradeBar> QuantConnect.Algorithm.QCAlgorithm.History (
Symbol symbol,
TimeSpan span,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol over the request span. The symbol must exist in the Securities collection.

Show Details

Parameters		
`Symbol`	symbol	The symbol to retrieve historical data for.
`TimeSpan`	span	The span over which to retrieve recent historical data.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`IEnumerable<TradeBar>` - An enumerable of slice containing the requested historical data.

Definition at line 485 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 22/27

```
IEnumerable<TradeBar> QuantConnect.Algorithm.QCAlgorithm.History (
Symbol symbol,
DateTime start,
DateTime end,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Gets the historical data for the specified symbol over the request span. The symbol must exist in the Securities collection.

Show Details

Parameters		
`Symbol`	symbol	The symbol to retrieve historical data for.
`DateTime`	start	The start time in the algorithm's time zone.
`DateTime`	end	The end time in the algorithm's time zone.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution to request.
`*Nullable<Boolean>`	fillForward	*(Optional)* True to fill forward missing data, False otherwise.
`*Nullable<Boolean>`	extendedMarketHours	*(Optional)* True to include extended market hours data, False otherwise.
`*Nullable<DataMappingMode>`	dataMappingMode	*(Optional)* The contract mapping mode to use for the security history request.
`*Nullable<DataNormalizationMode>`	dataNormalizationMode	*(Optional)* The price scaling mode to use for the securities history.
`*Nullable<Int32>`	contractDepthOffset	*(Optional)* The continuous contract desired offset from the current front month. For example, 0 will use the front month, 1 will use the back month contract.

Return

`IEnumerable<TradeBar>` - An enumerable of slice containing the requested historical data.

Definition at line 508 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 23/27

```
IEnumerable<Slice> QuantConnect.Algorithm.QCAlgorithm.History (
IEnumerable<Symbol> symbols,
TimeSpan span,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Executes the specified history request.

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
TimeSpan	span	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Nullable<Boolean>	fillForward	*(Optional)* /
*Nullable<Boolean>	extendedMarketHours	*(Optional)* /
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* /
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* /
*Nullable<Int32>	contractDepthOffset	*(Optional)* /

Return

IEnumerable<Slice> - The new IEnumerable<Slice> object.

Definition at line 545 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 24/27

```
IEnumerable<Slice> QuantConnect.Algorithm.QCAlgorithm.History (
IEnumerable<Symbol> symbols,
Int32 periods,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Executes the specified history request.

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
Int32	periods	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Nullable<Boolean>	fillForward	*(Optional)* /
*Nullable<Boolean>	extendedMarketHours	*(Optional)* /
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* /
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* /
*Nullable<Int32>	contractDepthOffset	*(Optional)* /

Return

IEnumerable<Slice> - The new IEnumerable<Slice> object.

Definition at line 569 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 25/27

```
IEnumerable<Slice> QuantConnect.Algorithm.QCAlgorithm.History (
IEnumerable<Symbol> symbols,
DateTime start,
DateTime end,
*Nullable<Resolution> resolution,
*Nullable<Boolean> fillForward,
*Nullable<Boolean> extendedMarketHours,
*Nullable<DataMappingMode> dataMappingMode,
*Nullable<DataNormalizationMode> dataNormalizationMode,
*Nullable<Int32> contractDepthOffset
)
```

Executes the specified history request.

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
DateTime	start	/
DateTime	end	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Nullable<Boolean>	fillForward	*(Optional)* /
*Nullable<Boolean>	extendedMarketHours	*(Optional)* /
*Nullable<DataMappingMode>	dataMappingMode	*(Optional)* /
*Nullable<DataNormalizationMode>	dataNormalizationMode	*(Optional)* /
*Nullable<Int32>	contractDepthOffset	*(Optional)* /

Return

IEnumerable<Slice> - The new IEnumerable<Slice> object.

Definition at line 593 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 26/27

```
IEnumerable<Slice> QuantConnect.Algorithm.QCAlgorithm.History (
 HistoryRequest request
)
```

Executes the specified history request.

Show Details

Parameters		
HistoryRequest	request	the history request to execute.

Return

IEnumerable<Slice> - An enumerable of slice satisfying the specified history request.

Definition at line 607 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

History() 27/27

```
IEnumerable<Slice> QuantConnect.Algorithm.QCAlgorithm.History (
 IEnumerable<HistoryRequest> requests
)
```

Show Details

Parameters		
IEnumerable<HistoryRequest>	requests	/

Return

IEnumerable<Slice> - The new IEnumerable<Slice> object.

Definition at line 618 of file Algorithm/QCAlgorithm.History.cs.

INDICATORS

HMA() 1/1

```
HullMovingAverage QuantConnect.Algorithm.QCAlgorithm.HMA (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new HullMovingAverage indicator. The Hull moving average is a series of nested weighted moving averages, is fast and smooth.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Hull moving average we want.
`Int32`	period	The period over which to compute the Hull moving average.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`HullMovingAverage` - The new `HullMovingAverage` object.

Definition at line 712 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

HT() 1/1

```
HilbertTransform QuantConnect.Algorithm.QCAlgorithm.HT (
Symbol symbol,
Int32 length,
Decimal inPhaseMultiplicationFactor,
Decimal quadratureMultiplicationFactor,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Hilbert Transform indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Hilbert transform we want.
`Int32`	length	The length of the FIR filter used in the calculation of the Hilbert Transform. This parameter determines the number of filter coefficients in the FIR filter.
`Decimal`	inPhaseMultiplicationFactor	The multiplication factor used in the calculation of the in-phase component of the Hilbert Transform. This parameter adjusts the sensitivity and responsiveness of the transform to changes in the input signal.
`Decimal`	quadratureMultiplicationFactor	The multiplication factor used in the calculation of the quadrature component of the Hilbert Transform. This parameter also adjusts the sensitivity and responsiveness of the transform to changes in the input signal.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`HilbertTransform` - The new `HilbertTransform` object.

Definition at line 694 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ICHIMOKU() 1/1

```
IchimokuKinkoHyo QuantConnect.Algorithm.QCAlgorithm.ICHIMOKU (
Symbol symbol,
Int32 tenkanPeriod,
Int32 kijunPeriod,
Int32 senkouAPeriod,
Int32 senkouBPeriod,
Int32 senkouADelayPeriod,
Int32 senkouBDelayPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new IchimokuKinkoHyo indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose ICHIMOKU we want.
Int32	tenkanPeriod	The period to calculate the Tenkan-sen period.
Int32	kijunPeriod	The period to calculate the Kijun-sen period.
Int32	senkouAPeriod	The period to calculate the Tenkan-sen period.
Int32	senkouBPeriod	The period to calculate the Tenkan-sen period.
Int32	senkouADelayPeriod	The period to calculate the Tenkan-sen period.
Int32	senkouBDelayPeriod	The period to calculate the Tenkan-sen period.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, TradeBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

IchimokuKinkoHyo - A new IchimokuKinkoHyo indicator with the specified periods and delays.

Definition at line 736 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

Identity() 1/3

```
Identity QuantConnect.Algorithm.QCAlgorithm.Identity (
 Symbol symbol,
 *Func<IBaseData, Decimal> selector,
 *String fieldName
)
```

Creates a new Identity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`Identity` - A new Identity indicator for the specified symbol and selector.

Definition at line 755 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

Identity() 2/3

```
Identity QuantConnect.Algorithm.QCAlgorithm.Identity (
Symbol symbol,
Resolution resolution,
*Func<IBaseData, Decimal> selector,
*String fieldName
)
```

Creates a new Identity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose values we want as an indicator.
`Resolution`	resolution	The desired resolution of the data.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
`*String`	fieldName	*(Optional)* The name of the field being selected.

Return

`Identity` - A new Identity indicator for the specified symbol and selector.

Definition at line 771 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

Identity() 3/3

```
Identity QuantConnect.Algorithm.QCAlgorithm.Identity (
Symbol symbol,
TimeSpan resolution,
*Func<IBaseData, Decimal> selector,
*String fieldName
)
```

Creates a new Identity indicator for the symbol The indicator will be automatically updated on the symbol's subscription resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose values we want as an indicator.
TimeSpan	resolution	The desired resolution of the data.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData, if None defaults to the .Value property (x => x.Value).
*String	fieldName	*(Optional)* The name of the field being selected.

Return

Identity - A new Identity indicator for the specified symbol and selector.

Definition at line 789 of file Algorithm/QCAlgorithm.Indicators.cs.

ALGORITHM FRAMEWORK HANDLING DATA

Initialize() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.Initialize (

)
```

Initialise the data and resolution required, as well as the cash and start-end dates for your algorithm. All algorithms must initialized.

Show Details

This method requires no argument input.

Return

`Void` - This method provides no return.

Definition at line 584 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS | SECURITIES AND PORTFOLIO

IsMarketOpen() 1/1

```
Boolean QuantConnect.Algorithm.QCAlgorithm.IsMarketOpen (
 Symbol symbol
)
```

Determines if the exchange for the specified symbol is open at the current time.

Show Details

Parameters		
`Symbol`	symbol	The symbol.

Return

`Boolean` - True if the exchange is considered open at the current time, False otherwise.

Definition at line 1381 of file Algorithm/QCAlgorithm.Trading.cs.

HANDLING DATA | SECURITIES AND PORTFOLIO

ISIN() 1/2

```
Symbol QuantConnect.Algorithm.QCAlgorithm.ISIN (
String isin,
*Nullable<DateTime> tradingDate
)
```

Converts an ISIN identifier into a `Symbol` .

Show Details

Parameters		
`String`	isin	The International Securities Identification Number (ISIN) of an asset.
`*Nullable<DateTime>`	tradingDate	*(Optional)* The date that the stock being looked up is/was traded at. The date is used to create a Symbol with the ticker set to the ticker the asset traded under on the trading date. .

Return

`Symbol` - Symbol corresponding to the ISIN. If no Symbol with a matching ISIN was found, returns None.

Definition at line 2896 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA SECURITIES AND PORTFOLIO

ISIN() 2/2

```
String QuantConnect.Algorithm.QCAlgorithm.ISIN (
Symbol symbol
)
```

Converts a `Symbol` into an ISIN identifier.

Show Details

Parameters		
`Symbol`	symbol	The `Symbol` .

Return

`String` - ISIN corresponding to the Symbol. If no matching ISIN is found, returns None.

Definition at line 2908 of file Algorithm/QCAlgorithm.cs.

INDICATORS

KAMA() 1/2

```
KaufmanAdaptiveMovingAverage QuantConnect.Algorithm.QCAlgorithm.KAMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new KaufmanAdaptiveMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose KAMA we want.
`Int32`	period	The period of the Efficiency Ratio (ER) of KAMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`KaufmanAdaptiveMovingAverage` - The KaufmanAdaptiveMovingAverage indicator for the requested symbol over the specified period.

Definition at line 806 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

KAMA() 2/2

```
KaufmanAdaptiveMovingAverage QuantConnect.Algorithm.QCAlgorithm.KAMA (
 Symbol symbol,
 Int32 period,
 Int32 fastEmaPeriod,
 Int32 slowEmaPeriod,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new KaufmanAdaptiveMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose KAMA we want.
`Int32`	period	The period of the Efficiency Ratio (ER).
`Int32`	fastEmaPeriod	The period of the fast EMA used to calculate the Smoothing Constant (SC).
`Int32`	slowEmaPeriod	The period of the slow EMA used to calculate the Smoothing Constant (SC).
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`KaufmanAdaptiveMovingAverage` - The KaufmanAdaptiveMovingAverage indicator for the requested symbol over the specified period.

Definition at line 822 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

KCH() 1/1

```
KeltnerChannels QuantConnect.Algorithm.QCAlgorithm.KCH (
Symbol symbol,
Int32 period,
Decimal k,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Keltner Channels indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Keltner Channel we seek.
`Int32`	period	The period over which to compute the Keltner Channels.
`Decimal`	k	The number of multiples of the `AverageTrueRange` from the middle band of the Keltner Channels.
`*MovingAverageType`	movingAverageType	*(Optional)* Specifies the type of moving average to be used as the middle line of the Keltner Channel.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`KeltnerChannels` - The Keltner Channel indicator for the requested symbol.

Definition at line 862 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

KER() 1/1

```
KaufmanEfficiencyRatio QuantConnect.Algorithm.QCAlgorithm.KER (
Symbol symbol,
*Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates an KaufmanEfficiencyRatio indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose EF we want.
`*Int32`	period	*(Optional)* The period of the EF.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`KaufmanEfficiencyRatio` - The KaufmanEfficiencyRatio indicator for the given parameters.

Definition at line 841 of file Algorithm/QCAlgorithm.Indicators.cs.

TRADING AND ORDERS

LimitIfTouchedOrder() 1/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.LimitIfTouchedOrder (
Symbol symbol,
Int32 quantity,
Decimal triggerPrice,
Decimal limitPrice,
*String tag,
*IOrderProperties orderProperties
)
```

Send a limit if touched order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Int32`	quantity	Quantity of shares for limit order.
`Decimal`	triggerPrice	Trigger price for this order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 539 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

LimitIfTouchedOrder() 2/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.LimitIfTouchedOrder (
 Symbol symbol,
 Double quantity,
 Decimal triggerPrice,
 Decimal limitPrice,
 *String tag,
 *IOrderProperties orderProperties
 )
```

Send a limit if touched order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Double`	quantity	Quantity of shares for limit order.
`Decimal`	triggerPrice	Trigger price for this order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 555 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

LimitIfTouchedOrder() 3/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.LimitIfTouchedOrder (
 Symbol symbol,
 Decimal quantity,
 Decimal triggerPrice,
 Decimal limitPrice,
 *String tag,
 *IOrderProperties orderProperties
 )
```

Send a limit if touched order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Decimal`	quantity	Quantity of shares for limit order.
`Decimal`	triggerPrice	Trigger price for this order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 571 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

LimitOrder() 1/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.LimitOrder (
Symbol symbol,
Int32 quantity,
Decimal limitPrice,
*String tag,
*IOrderProperties orderProperties
)
```

Send a limit order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Int32`	quantity	Quantity of shares for limit order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 391 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

LimitOrder() 2/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.LimitOrder (
Symbol symbol,
Double quantity,
Decimal limitPrice,
*String tag,
*IOrderProperties orderProperties
)
```

Send a limit order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Double`	quantity	Quantity of shares for limit order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 406 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

LimitOrder() 3/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.LimitOrder (
Symbol symbol,
Decimal quantity,
Decimal limitPrice,
*String tag,
*IOrderProperties orderProperties
)
```

Send a limit order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Decimal`	quantity	Quantity of shares for limit order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 421 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Liquidate() 1/1

```
List<Int32> QuantConnect.Algorithm.QCAlgorithm.Liquidate (
*Symbol symbolToLiquidate,
*String tag
)
```

Liquidate all holdings and cancel open orders. Called at the end of day for tick-strategies.

Show Details

Parameters		
`*Symbol`	symbolToLiquidate	*(Optional)* Symbols we wish to liquidate.
`*String`	tag	*(Optional)* Custom tag to know who is calling this.

Return

`List<Int32>` - Array of order Id for liquidated symbols.

Definition at line 1063 of file Algorithm/QCAlgorithm.Trading.cs.

LOGGING

Log() 1/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Log (
PyObject message
)
```

Added another method for logging if user guessed.

Show Details

Parameters		
PyObject	message	String message to log.

Return

Void - This method provides no return.

Definition at line 1234 of file Algorithm/QCAlgorithm.Python.cs.

LOGGING

Log() 2/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Log (
String message
)
```

Added another method for logging if user guessed.

Show Details

Parameters		
String	message	String message to log.

Return

`Void` - This method provides no return.

Definition at line 2503 of file Algorithm/QCAlgorithm.cs.

LOGGING

Log() 3/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Log (
 Int32 message
)
```

Added another method for logging if user guessed.

Show Details

Parameters		
`Int32`	message	Int message to log.

Return

`Void` - This method provides no return.

Definition at line 2516 of file Algorithm/QCAlgorithm.cs.

LOGGING

Log() 4/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Log (
 Double message
)
```

Added another method for logging if user guessed.

Show Details

Parameters		
Double	message	Double message to log.

Return

Void - This method provides no return.

Definition at line 2528 of file Algorithm/QCAlgorithm.cs.

LOGGING

Log() 5/5

```
Void QuantConnect.Algorithm.QCAlgorithm.Log (
Decimal message
)
```

Added another method for logging if user guessed.

Show Details

Parameters		
Decimal	message	Decimal message to log.

Return

Void - This method provides no return.

Definition at line 2540 of file Algorithm/QCAlgorithm.cs.

INDICATORS

LOGR() 1/1

```
LogReturn QuantConnect.Algorithm.QCAlgorithm.LOGR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new LogReturn indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose log return we seek.
`Int32`	period	The period of the log return.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`LogReturn` - log return indicator for the requested symbol.

Definition at line 880 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

LSMA() 1/1

```
LeastSquaresMovingAverage QuantConnect.Algorithm.QCAlgorithm.LSMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates and registers a new Least Squares Moving Average instance.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose LSMA we seek.
`Int32`	period	The LSMA period. Normally 14.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`LeastSquaresMovingAverage` - A LeastSquaredMovingAverage configured with the specified period.

Definition at line 898 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

LWMA() 1/1

```
LinearWeightedMovingAverage QuantConnect.Algorithm.QCAlgorithm.LWMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new LinearWeightedMovingAverage indicator. This indicator will linearly distribute the weights across the periods.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose LWMA we want.
`Int32`	period	The period over which to compute the LWMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`LinearWeightedMovingAverage` - The new `LinearWeightedMovingAverage` object.

Definition at line 917 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MACD() 1/1

```
MovingAverageConvergenceDivergence QuantConnect.Algorithm.QCAlgorithm.MACD (
Symbol symbol,
Int32 fastPeriod,
Int32 slowPeriod,
Int32 signalPeriod,
*MovingAverageType type,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a MACD indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose MACD we want.
Int32	fastPeriod	The period for the fast moving average.
Int32	slowPeriod	The period for the slow moving average.
Int32	signalPeriod	The period for the signal moving average.
*MovingAverageType	type	*(Optional)* The type of moving average to use for the MACD.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

MovingAverageConvergenceDivergence - The moving average convergence divergence between the fast and slow averages.

Definition at line 938 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MAD() 1/1

```
MeanAbsoluteDeviation QuantConnect.Algorithm.QCAlgorithm.MAD (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new MeanAbsoluteDeviation indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MeanAbsoluteDeviation we want.
`Int32`	period	The period over which to compute the MeanAbsoluteDeviation.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MeanAbsoluteDeviation` - The MeanAbsoluteDeviation indicator for the requested symbol over the specified period.

Definition at line 956 of file Algorithm/QCAlgorithm.Indicators.cs.

TRADING AND ORDERS

MarketOnCloseOrder() 1/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOnCloseOrder (
 Symbol symbol,
 Int32 quantity,
 *String tag,
 *IOrderProperties orderProperties
)
```

Market on close order implementation: Send a market order when the exchange closes.

Show Details

Parameters		
`Symbol`	symbol	The symbol to be ordered.
`Int32`	quantity	The number of shares to required.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 342 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOnCloseOrder() 2/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOnCloseOrder (
Symbol symbol,
Double quantity,
*String tag,
*IOrderProperties orderProperties
)
```

Market on close order implementation: Send a market order when the exchange closes.

Show Details

Parameters		
`Symbol`	symbol	The symbol to be ordered.
`Double`	quantity	The number of shares to required.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 356 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOnCloseOrder() 3/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOnCloseOrder (
Symbol symbol,
Decimal quantity,
*String tag,
*IOrderProperties orderProperties
)
```

Market on close order implementation: Send a market order when the exchange closes.

Show Details

Parameters		
`Symbol`	symbol	The symbol to be ordered.
`Decimal`	quantity	The number of shares to required.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 370 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOnOpenOrder() 1/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOnOpenOrder (
Symbol symbol,
Double quantity,
*String tag,
*IOrderProperties orderProperties
)
```

Market on open order implementation: Send a market order when the exchange opens.

Show Details

Parameters		
`Symbol`	symbol	The symbol to be ordered.
`Double`	quantity	The number of shares to required.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 294 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOnOpenOrder() 2/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOnOpenOrder (
Symbol symbol,
Int32 quantity,
*String tag,
*IOrderProperties orderProperties
)
```

Market on open order implementation: Send a market order when the exchange opens.

Show Details

Parameters		
`Symbol`	symbol	The symbol to be ordered.
`Int32`	quantity	The number of shares to required.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 308 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOnOpenOrder() 3/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOnOpenOrder (
Symbol symbol,
Decimal quantity,
*String tag,
*IOrderProperties orderProperties
)
```

Market on open order implementation: Send a market order when the exchange opens.

Show Details

Parameters		
`Symbol`	symbol	The symbol to be ordered.
`Decimal`	quantity	The number of shares to required.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 322 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOrder() 1/4

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOrder (
Symbol symbol,
Int32 quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Market order implementation: Send a market order and wait for it to be filled.

Show Details

Parameters		
`Symbol`	symbol	Symbol of the MarketType Required.
`Int32`	quantity	Number of shares to request.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 206 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOrder() 2/4

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOrder (
Symbol symbol,
Double quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Market order implementation: Send a market order and wait for it to be filled.

Show Details

Parameters		
`Symbol`	symbol	Symbol of the MarketType Required.
`Double`	quantity	Number of shares to request.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 221 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOrder() 3/4

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOrder (
Symbol symbol,
Decimal quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Market order implementation: Send a market order and wait for it to be filled.

Show Details

Parameters		
`Symbol`	symbol	Symbol of the MarketType Required.
`Decimal`	quantity	Number of shares to request.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 236 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

MarketOrder() 4/4

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.MarketOrder (
Security security,
Decimal quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Market order implementation: Send a market order and wait for it to be filled.

Show Details

Parameters		
`Security`	security	Symbol of the MarketType Required.
`Decimal`	quantity	Number of shares to request.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 252 of file Algorithm/QCAlgorithm.Trading.cs.

INDICATORS

MASS() 1/1

```
MassIndex QuantConnect.Algorithm.QCAlgorithm.MASS (
 Symbol symbol,
 *Int32 emaPeriod,
 *Int32 sumPeriod,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Creates a new Mass Index indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Mass Index we want.
`*Int32`	emaPeriod	*(Optional)* The period used by both EMA.
`*Int32`	sumPeriod	*(Optional)* The sum period.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`MassIndex` - The Mass Index indicator for the requested symbol over the specified period.

Definition at line 1073 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MAX() 1/1

```
Maximum QuantConnect.Algorithm.QCAlgorithm.MAX (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new Maximum indicator to compute the maximum value.

Show Details

Parameters		
Symbol	symbol	The symbol whose max we want.
Int32	period	The look back period over which to compute the max value.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None and the symbol is of type TradeBar defaults to the High property, otherwise it defaults to Value property of BaseData (x => x.Value).

Return

Maximum - A Maximum indicator that compute the max value and the periods since the max value.

Definition at line 1017 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MFI() 1/1

```
MoneyFlowIndex QuantConnect.Algorithm.QCAlgorithm.MFI (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new MoneyFlowIndex indicator. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MFI we want.
`Int32`	period	The period over which to compute the MFI.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`MoneyFlowIndex` - The MoneyFlowIndex indicator for the requested symbol over the specified period.

Definition at line 1053 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MIDPOINT() 1/1

```
MidPoint QuantConnect.Algorithm.QCAlgorithm.MIDPOINT (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new MidPoint indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MIDPOINT we want.
`Int32`	period	The period over which to compute the MIDPOINT.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MidPoint` - The MidPoint indicator for the requested symbol over the specified period.

Definition at line 1091 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MIDPRICE() 1/1

```
MidPrice QuantConnect.Algorithm.QCAlgorithm.MIDPRICE (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new MidPrice indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose MIDPRICE we want.
`Int32`	period	The period over which to compute the MIDPRICE.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`MidPrice` - The MidPrice indicator for the requested symbol over the specified period.

Definition at line 1109 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MIN() 1/1

```
Minimum QuantConnect.Algorithm.QCAlgorithm.MIN (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Minimum indicator to compute the minimum value.

Show Details

Parameters		
Symbol	symbol	The symbol whose min we want.
Int32	period	The look back period over which to compute the min value.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None and the symbol is of type TradeBar defaults to the Low property, otherwise it defaults to Value property of BaseData (x => x.Value).

Return

Minimum - A Minimum indicator that compute the in value and the periods since the min value.

Definition at line 1128 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MOM() 1/1

```
Momentum QuantConnect.Algorithm.QCAlgorithm.MOM (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Momentum indicator. This will compute the absolute n-period change in the security. The indicator

will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose momentum we want.
`Int32`	period	The period over which to compute the momentum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`Momentum` - The momentum indicator for the requested symbol over the specified period.

Definition at line 1164 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MOMERSION() 1/1

```
MomersionIndicator QuantConnect.Algorithm.QCAlgorithm.MOMERSION (
Symbol symbol,
Nullable<Int32> minPeriod,
Int32 fullPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Momersion indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Momersion we want.
`Nullable<Int32>`	minPeriod	The minimum period over which to compute the Momersion. Must be greater than 3. If None, only full period will be used in computations.
`Int32`	fullPeriod	The full period over which to compute the Momersion.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MomersionIndicator` - The Momersion indicator for the requested symbol over the specified period.

Definition at line 1183 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MOMP() 1/1

```
MomentumPercent QuantConnect.Algorithm.QCAlgorithm.MOMP (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new MomentumPercent indicator. This will compute the n-period percent change in the security. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose momentum we want.
`Int32`	period	The period over which to compute the momentum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`MomentumPercent` - The momentum indicator for the requested symbol over the specified period.

Definition at line 1202 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MOSC() 1/2

```
McClellanOscillator QuantConnect.Algorithm.QCAlgorithm.MOSC (
IEnumerable<Symbol> symbols,
*Int32 fastPeriod,
*Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new McClellan Oscillator indicator.

Show Details

Parameters		
`IEnumerable<Symbol>`	symbols	/
`*Int32`	fastPeriod	*(Optional)* /
`*Int32`	slowPeriod	*(Optional)* /
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* /

Return

`McClellanOscillator` - The new `McClellanOscillator` object.

Definition at line 2044 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MOSC() 2/2

```
McClellanOscillator QuantConnect.Algorithm.QCAlgorithm.MOSC (
Symbol> symbols,
*Int32 fastPeriod,
*Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new McClellan Oscillator indicator.

Show Details

Parameters		
`Symbol>`	symbols	The symbols whose McClellan Oscillator we want.
`*Int32`	fastPeriod	*(Optional)* Fast period EMA of advance decline difference.
`*Int32`	slowPeriod	*(Optional)* Slow period EMA of advance decline difference.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`McClellanOscillator` - The McClellan Oscillator indicator for the requested symbol over the specified period.

Definition at line 2059 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MSI() 1/2

```
McClellanSummationIndex QuantConnect.Algorithm.QCAlgorithm.MSI (
IEnumerable<Symbol> symbols,
*Int32 fastPeriod,
*Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new McClellan Summation Index indicator.

Show Details

Parameters		
IEnumerable<Symbol>	symbols	/
*Int32	fastPeriod	*(Optional)* /
*Int32	slowPeriod	*(Optional)* /
*Nullable<Resolution>	resolution	*(Optional)* /
*Func<IBaseData, TradeBar>	selector	*(Optional)* /

Return

`McClellanSummationIndex` - The new `McClellanSummationIndex` object.

Definition at line 2082 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

MSI() 2/2

```
McClellanSummationIndex QuantConnect.Algorithm.QCAlgorithm.MSI (
Symbol> symbols,
*Int32 fastPeriod,
*Int32 slowPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new McClellan Summation Index indicator.

Show Details

Parameters		
Symbol>	symbols	The symbols whose McClellan Summation Index we want.
*Int32	fastPeriod	*(Optional)* Fast period EMA of advance decline difference.
*Int32	slowPeriod	*(Optional)* Slow period EMA of advance decline difference.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, TradeBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`McClellanSummationIndex` - The McClellan Summation Index indicator for the requested symbol over the specified period.

Definition at line 2097 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

NATR() 1/1

```
NormalizedAverageTrueRange QuantConnect.Algorithm.QCAlgorithm.NATR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new NormalizedAverageTrueRange indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose NATR we want.
Int32	period	The period over which to compute the NATR.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, IBaseDataBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

NormalizedAverageTrueRange - The NormalizedAverageTrueRange indicator for the requested symbol over the specified period.

Definition at line 1220 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

OBV() 1/1

```
OnBalanceVolume QuantConnect.Algorithm.QCAlgorithm.OBV (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new On Balance Volume indicator. This will compute the cumulative total volume based on whether the close price being higher or lower than the previous period. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose On Balance Volume we seek.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`OnBalanceVolume` - The On Balance Volume indicator for the requested symbol.

Definition at line 1239 of file Algorithm/QCAlgorithm.Indicators.cs.

TRADING AND ORDERS

OnAssignmentOrderEvent() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnAssignmentOrderEvent (
OrderEvent assignmentEvent
)
```

Option assignment event handler. On an option assignment event for short legs the resulting information is passed to this method.

Show Details

Parameters		
`OrderEvent`	assignmentEvent	Option exercise event details containing details of the assignment.

Return

`Void` - This method provides no return.

Definition at line 1045 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

OnData() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnData (
 Slice slice
)
```

Event - v3.0 DATA EVENT HANDLER: (Pattern) Basic template for user to override for receiving all subscription data in a single event.

Show Details

Parameters		
Slice	slice	The current slice of data keyed by symbol string.

Return

Void - This method provides no return.

Definition at line 857 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

OnEndOfAlgorithm() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnEndOfAlgorithm (
)
```

End of algorithm run event handler. This method is called at the end of a backtest or live trading operation. Intended for closing out logs.

Show Details

This method requires no argument input.

Return

Void - This method provides no return.

Definition at line 1023 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

OnEndOfDay() 1/3

```
Void QuantConnect.Algorithm.QCAlgorithm.OnEndOfDay (
)
```

End of a trading day event handler. This method is called at the end of the algorithm day (or multiple times if trading multiple assets).

Show Details

This method requires no argument input.

Return

`Void` - This method provides no return.

Definition at line 991 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

OnEndOfDay() 2/3

```
Void QuantConnect.Algorithm.QCAlgorithm.OnEndOfDay (
 String symbol
)
```

End of a trading day event handler. This method is called at the end of the algorithm day (or multiple times if trading multiple assets).

Show Details

Parameters		
`String`	symbol	Asset symbol for this end of day event. Forex and equities have different closing hours.

Return

`Void` - This method provides no return.

Definition at line 1005 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

OnEndOfDay() 3/3

```
Void QuantConnect.Algorithm.QCAlgorithm.OnEndOfDay (
 Symbol symbol
)
```

End of a trading day event handler. This method is called at the end of the algorithm day (or multiple times if trading multiple assets).

Show Details

Parameters		
`Symbol`	symbol	Asset symbol for this end of day event. Forex and equities have different closing hours.

Return

`Void` - This method provides no return.

Definition at line 1014 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

OnEndOfTimeStep() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnEndOfTimeStep (

)
```

Invoked at the end of every time step. This allows the algorithm to process events before advancing to the next time step.

Show Details

This method requires no argument input.

Return

`Void` - This method provides no return.

Definition at line 68 of file Algorithm/QCAlgorithm.Universe.cs.

ALGORITHM FRAMEWORK HANDLING DATA

OnFrameworkData() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnFrameworkData (
Slice slice
)
```

Used to send data updates to algorithm framework models.

Show Details

Parameters		
`Slice`	slice	The current data slice.

Return

`Void` - This method provides no return.

Definition at line 107 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK UNIVERSES

OnFrameworkSecuritiesChanged() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnFrameworkSecuritiesChanged (
SecurityChanges changes
)
```

Used to send security changes to algorithm framework models.

Show Details

Parameters		
SecurityChanges	changes	Security additions/removals for this time step.

Return

Void - This method provides no return.

Definition at line 260 of file Algorithm/QCAlgorithm.Framework.cs.

MODELING TRADING AND ORDERS

OnMarginCall() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnMarginCall (
List<SubmitOrderRequest> requests
)
```

Margin call event handler. This method is called right before the margin call orders are placed in the market.

Show Details

Parameters		
List<SubmitOrderRequest>	requests	The orders to be executed to bring this algorithm within margin limits.

Return

Void - This method provides no return.

Definition at line 969 of file Algorithm/QCAlgorithm.cs.

MODELING TRADING AND ORDERS

OnMarginCallWarning() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnMarginCallWarning (
)
```

Margin call warning event handler. This method is called when Portfolio.MarginRemaining is under 5% of your Portfolio.TotalPortfolioValue.

Show Details

This method requires no argument input.

Return

`Void` - This method provides no return.

Definition at line 978 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS

OnOrderEvent() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnOrderEvent (
 OrderEvent orderEvent
)
```

Order fill event handler. On an order fill update the resulting information is passed to this method.

Show Details

Parameters		
`OrderEvent`	orderEvent	Order event details containing details of the events.

Return

`Void` - This method provides no return.

Definition at line 1034 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

OnWarmupFinished() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.OnWarmupFinished (
)
```

Called when the algorithm has completed initialization and warm up.

Show Details

This method requires no argument input.

Return

`Void` - This method provides no return.

Definition at line 668 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS

Order() 1/8

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Order (
 Symbol symbol,
 Double quantity
)
```

Issue an order/trade for asset: Alias wrapper for Order(string, int);.

Show Details

Parameters		
`Symbol`	symbol	Symbol to order.
`Double`	quantity	Quantity to order.

Return

`OrderTicket` - The order ticket instance.

Definition at line 151 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Order() 2/8

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Order (
Symbol symbol,
Int32 quantity
)
```

Issue an order/trade for asset.

Show Details

Parameters		
Symbol	symbol	Symbol to order.
Int32	quantity	Quantity to order.

Return

OrderTicket - The order ticket instance.

Definition at line 163 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Order() 3/8

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Order (
Symbol symbol,
Decimal quantity
)
```

Issue an order/trade for asset.

Show Details

Parameters		
`Symbol`	symbol	Symbol to order.
`Decimal`	quantity	Quantity to order.

Return

`OrderTicket` - The order ticket instance.

Definition at line 175 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Order() 4/8

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Order (
Symbol symbol,
Decimal quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Wrapper for market order method: submit a new order for quantity of symbol using type order.

Show Details

Parameters		
`Symbol`	symbol	Symbol of the MarketType Required.
`Decimal`	quantity	Number of shares to request.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* Place a custom order property or tag (e.g. indicator data).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 191 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Order() 5/8

```
IEnumerable<OrderTicket> QuantConnect.Algorithm.QCAlgorithm.Order (
OptionStrategy strategy,
Int32 quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Issue an order/trade for buying/selling an option strategy.

Show Details

Parameters		
`OptionStrategy`	strategy	Specification of the strategy to trade.
`Int32`	quantity	Quantity of the strategy to trade.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`IEnumerable<OrderTicket>` - Sequence of order tickets.

Definition at line 658 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Order() 6/8

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Order (
Symbol symbol,
Int32 quantity,
OrderType type,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Obsolete implementation of Order method accepting a OrderType. This was deprecated since it was impossible to generate other orders via this method. Any calls to this method will always default to a Market Order.

Show Details

Parameters		
`Symbol`	symbol	Symbol we want to purchase.
`Int32`	quantity	Quantity to buy, + is long, - short.
`OrderType`	type	Order Type. *Options: ['Market', 'Limit', 'StopMarket', 'StopLimit', 'MarketOnOpen', 'MarketOnClose', 'OptionExercise', 'LimitIfTouched', 'ComboMarket', 'ComboLimit', 'ComboLegLimit']*
`*Boolean`	asynchronous	*(Optional)* Don't wait for the response, just submit order and move on.
`*String`	tag	*(Optional)* Custom data for this order.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 1342 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Order() 7/8

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Order (
Symbol symbol,
Decimal quantity,
OrderType type
)
```

Obsolete method for placing orders.

Show Details

Parameters		
`Symbol`	symbol	Symbol we want to order.
`Decimal`	quantity	The quantity to order.
`OrderType`	type	The order type.

Return

`OrderTicket` - The order ticket instance.

Definition at line 1356 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Order() 8/8

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Order (
Symbol symbol,
Int32 quantity,
OrderType type
)
```

Obsolete method for placing orders.

Show Details

Parameters		
`Symbol`	symbol	Symbol we want to order.
`Int32`	quantity	The quantity to order.
`OrderType`	type	The order type.

Return

`OrderTicket` - The order ticket instance.

Definition at line 1370 of file Algorithm/QCAlgorithm.Trading.cs.

CHARTING

Plot() 1/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String chart,
String series,
Int32 value
)
```

Plot a chart to string chart name, using string series name, with int value.

Show Details

Parameters		
String	chart	/
String	series	/
Int32	value	/

Return

Void - This method provides no return.

Definition at line 149 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Plot() 2/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String chart,
String series,
Single value
)
```

Plot a chart to string chart name, using string series name, with float value.

Show Details

Parameters		
String	chart	/
String	series	/
Single	value	/

Return

Void - This method provides no return.

Definition at line 159 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Plot() 3/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
 String chart,
 String series,
 Decimal value
)
```

Plot a value to a chart of string-chart name, with string series name, and decimal value. If chart does not exist, create it.

Show Details

Parameters		
String	chart	Chart name.
String	series	Series name.
Decimal	value	Value of the point.

Return

Void - This method provides no return.

Definition at line 171 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Plot() 4/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String chart,
IndicatorBase> indicators
)
```

Plots the value of each indicator on the chart.

Show Details

Parameters		
String	chart	The chart's name.
IndicatorBase>	indicators	The indicators to plot.

Return

Void - This method provides no return.

Definition at line 249 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Plot() 5/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String series,
PyObject pyObject
)
```

Plot a chart using string series name, with value.

Show Details

Parameters		
String	series	Name of the plot series.
PyObject	pyObject	PyObject with the value to plot.

Return

Void - This method provides no return.

Definition at line 690 of file Algorithm/QCAlgorithm.Python.cs.

CHARTING

Plot() 6/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
 String chart,
 Indicator first,
 *Indicator second,
 *Indicator third,
 *Indicator fourth
 )
```

Plots the value of each indicator on the chart.

Show Details

Parameters		
String	chart	The chart's name.
Indicator	first	The first indicator to plot.
*Indicator	second	*(Optional)* The second indicator to plot.
*Indicator	third	*(Optional)* The third indicator to plot.
*Indicator	fourth	*(Optional)* The fourth indicator to plot.

Return

Void - This method provides no return.

Definition at line 724 of file Algorithm/QCAlgorithm.Python.cs.

CHARTING

Plot() 7/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String chart,
BarIndicator first,
*BarIndicator second,
*BarIndicator third,
*BarIndicator fourth
)
```

Plots the value of each indicator on the chart.

Show Details

Parameters		
String	chart	The chart's name.
BarIndicator	first	The first indicator to plot.
*BarIndicator	second	*(Optional)* The second indicator to plot.
*BarIndicator	third	*(Optional)* The third indicator to plot.
*BarIndicator	fourth	*(Optional)* The fourth indicator to plot.

Return

Void - This method provides no return.

Definition at line 739 of file Algorithm/QCAlgorithm.Python.cs.

CHARTING

Plot() 8/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String chart,
TradeBarIndicator first,
*TradeBarIndicator second,
*TradeBarIndicator third,
*TradeBarIndicator fourth
)
```

Plots the value of each indicator on the chart.

Show Details

Parameters		
String	chart	The chart's name.
TradeBarIndicator	first	The first indicator to plot.
*TradeBarIndicator	second	*(Optional)* The second indicator to plot.
*TradeBarIndicator	third	*(Optional)* The third indicator to plot.
*TradeBarIndicator	fourth	*(Optional)* The fourth indicator to plot.

Return

Void - This method provides no return.

Definition at line 754 of file Algorithm/QCAlgorithm.Python.cs.

CHARTING

Plot() 9/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
 String series,
 Decimal value
)
```

Plot a chart using string series name, with value.

Show Details

Parameters		
String	series	Name of the plot series.
Decimal	value	Value to plot.

Return

Void - This method provides no return.

Definition at line 65 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Plot() 10/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String series,
Double value
)
```

Plot a chart using string series name, with double value.

Show Details

Parameters		
String	series	/
Double	value	/

Return

Void - This method provides no return.

Definition at line 110 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Plot() 11/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String series,
Int32 value
)
```

Plot a chart using string series name, with int value.

Show Details

Parameters		
String	series	/
Int32	value	/

Return

Void - This method provides no return.

Definition at line 119 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Plot() 12/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String series,
Single value
)
```

Plot a chart using string series name, with float value.

Show Details

Parameters		
String	series	/
Single	value	/

Return

Void - This method provides no return.

Definition at line 129 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Plot() 13/13

```
Void QuantConnect.Algorithm.QCAlgorithm.Plot (
String chart,
String series,
Double value
)
```

Plot a chart to string chart name, using string series name, with double value.

Show Details

Parameters		
String	chart	/
String	series	/
Double	value	/

Return

Void - This method provides no return.

Definition at line 139 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING INDICATORS

PlotIndicator() 1/4

```
Void QuantConnect.Algorithm.QCAlgorithm.PlotIndicator (
String chart,
IndicatorBase> indicators
)
```

Automatically plots each indicator when a new value is available.

Show Details

Parameters		
String	chart	/
IndicatorBase>	indicators	/

Return

Void - This method provides no return.

Definition at line 261 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING INDICATORS

PlotIndicator() 2/4

```
Void QuantConnect.Algorithm.QCAlgorithm.PlotIndicator (
String chart,
Boolean waitForReady,
IndicatorBase> indicators
)
```

Automatically plots each indicator when a new value is available, optionally waiting for indicator.IsReady to return True.

Show Details

Parameters		
String	chart	/
Boolean	waitForReady	/
IndicatorBase>	indicators	/

Return

Void - This method provides no return.

Definition at line 271 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING INDICATORS

PlotIndicator() 3/4

```
Void QuantConnect.Algorithm.QCAlgorithm.PlotIndicator (
String chart,
PyObject first,
*PyObject second,
*PyObject third,
*PyObject fourth
)
```

Automatically plots each indicator when a new value is available.

Show Details

Parameters		
String	chart	/
PyObject	first	/
*PyObject	second	*(Optional)* /
*PyObject	third	*(Optional)* /
*PyObject	fourth	*(Optional)* /

Return

Void - This method provides no return.

Definition at line 763 of file Algorithm/QCAlgorithm.Python.cs.

CHARTING INDICATORS

PlotIndicator() 4/4

```
Void QuantConnect.Algorithm.QCAlgorithm.PlotIndicator (
String chart,
Boolean waitForReady,
PyObject first,
*PyObject second,
*PyObject third,
*PyObject fourth
)
```

Automatically plots each indicator when a new value is available.

Show Details

Parameters		
`String`	chart	/
`Boolean`	waitForReady	/
`PyObject`	first	/
`*PyObject`	second	*(Optional)* /
`*PyObject`	third	*(Optional)* /
`*PyObject`	fourth	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 774 of file Algorithm/QCAlgorithm.Python.cs.

INDICATORS

PPHL() 1/1

```
PivotPointsHighLow QuantConnect.Algorithm.QCAlgorithm.PPHL (
 Symbol symbol,
 Int32 lengthHigh,
 Int32 lengthLow,
 *Int32 lastStoredValues,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new PivotPointsHighLow indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose PPHL we seek.
Int32	lengthHigh	The number of surrounding bars whose high values should be less than the current bar's for the bar high to be marked as high pivot point.
Int32	lengthLow	The number of surrounding bars whose low values should be more than the current bar's for the bar low to be marked as low pivot point.
*Int32	lastStoredValues	*(Optional)* The number of last stored indicator values.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, IBaseDataBar>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

PivotPointsHighLow - The PivotPointsHighLow indicator for the requested symbol.

Definition at line 1259 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

PPO() 1/1

```
PercentagePriceOscillator QuantConnect.Algorithm.QCAlgorithm.PPO (
 Symbol symbol,
 Int32 fastPeriod,
 Int32 slowPeriod,
 MovingAverageType movingAverageType,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new PercentagePriceOscillator indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose PPO we want.
Int32	fastPeriod	The fast moving average period.
Int32	slowPeriod	The slow moving average period.
MovingAverageType	movingAverageType	The type of moving average to use.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

PercentagePriceOscillator - The PercentagePriceOscillator indicator for the requested symbol over the specified period.

Definition at line 1279 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

PSAR() 1/1

```
ParabolicStopAndReverse QuantConnect.Algorithm.QCAlgorithm.PSAR (
 Symbol symbol,
 *Decimal afStart,
 *Decimal afIncrement,
 *Decimal afMax,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, IBaseDataBar> selector
 )
```

Creates a new Parabolic SAR indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose PSAR we seek.
`*Decimal`	afStart	*(Optional)* Acceleration factor start value. Normally 0.02.
`*Decimal`	afIncrement	*(Optional)* Acceleration factor increment value. Normally 0.02.
`*Decimal`	afMax	*(Optional)* Acceleration factor max value. Normally 0.2.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`ParabolicStopAndReverse` - A ParabolicStopAndReverse configured with the specified periods.

Definition at line 1299 of file Algorithm/QCAlgorithm.Indicators.cs.

LOGGING

Quit() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.Quit (
 PyObject message
)
```

Terminate the algorithm after processing the current event handler.

Show Details

Parameters		
`PyObject`	message	Exit message to display on quitting.

Return

`Void` - This method provides no return.

Definition at line 1244 of file Algorithm/QCAlgorithm.Python.cs.

LOGGING

Quit() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.Quit (
*String message
)
```

Terminate the algorithm after processing the current event handler.

Show Details

Parameters		
*String	message	*(Optional)* Exit message to display on quitting.

Return

Void - This method provides no return.

Definition at line 2615 of file Algorithm/QCAlgorithm.cs.

INDICATORS

RC() 1/1

```
RegressionChannel QuantConnect.Algorithm.QCAlgorithm.RC (
Symbol symbol,
Int32 period,
Decimal k,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RegressionChannel indicator which will compute the LinearRegression, UpperChannel and LowerChannel lines, the intercept and slope.

Show Details

Parameters		
Symbol	symbol	The symbol whose RegressionChannel we seek.
Int32	period	The period of the standard deviation and least square moving average (linear regression line).
Decimal	k	The number of standard deviations specifying the distance between the linear regression and upper or lower channel lines.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RegressionChannel` - A Regression Channel configured with the specified period and number of standard deviation.

Definition at line 1318 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

RDV() 1/1

```
RelativeDailyVolume QuantConnect.Algorithm.QCAlgorithm.RDV (
Symbol symbol,
*Int32 period,
*Resolution resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an RelativeDailyVolume indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RDV we want.
`*Int32`	period	*(Optional)* The period of the RDV.
`*Resolution`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`RelativeDailyVolume` - The Relative Volume indicator for the given parameters.

Definition at line 1450 of file Algorithm/QCAlgorithm.Indicators.cs.

CHARTING

Record() 1/3

```
Void QuantConnect.Algorithm.QCAlgorithm.Record (
 String series,
 Int32 value
)
```

Plot a chart using string series name, with int value. Alias of Plot();.

Show Details

Parameters		
`String`	series	/
`Int32`	value	/

Return

`Void` - This method provides no return.

Definition at line 77 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Record() 2/3

```
Void QuantConnect.Algorithm.QCAlgorithm.Record (
String series,
Double value
)
```

Plot a chart using string series name, with double value. Alias of Plot();.

Show Details

Parameters		
String	series	/
Double	value	/

Return

Void - This method provides no return.

Definition at line 87 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

Record() 3/3

```
Void QuantConnect.Algorithm.QCAlgorithm.Record (
String series,
Decimal value
)
```

Plot a chart using string series name, with decimal value. Alias of Plot();.

Show Details

Parameters		
String	series	/
Decimal	value	/

Return

Void - This method provides no return.

Definition at line 99 of file Algorithm/QCAlgorithm.Plotting.cs.

INDICATORS CONSOLIDATING DATA

RegisterIndicator() 1/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
PyObject indicator,
*Nullable<Resolution> resolution,
*PyObject selector
)
```

Registers the consolidator to receive automatic updates as well as configures the indicator to receive updates from the consolidator.

Show Details

Parameters		
Symbol	symbol	The symbol to register against.
PyObject	indicator	The indicator to receive data from the consolidator.
*Nullable<Resolution>	resolution	*(Optional)* The resolution at which to send data to the indicator, None to use the same resolution as the subscription.
*PyObject	selector	*(Optional)* Selects a value from the BaseData send into the indicator, if None defaults to a cast (x => (T)x).

Return

Void - This method provides no return.

Definition at line 545 of file Algorithm/QCAlgorithm.Python.cs.

INDICATORS CONSOLIDATING DATA

RegisterIndicator() 2/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
PyObject indicator,
*Nullable<TimeSpan> resolution,
*PyObject selector
)
```

Registers the consolidator to receive automatic updates as well as configures the indicator to receive updates from the consolidator.

Show Details

Parameters		
Symbol	symbol	The symbol to register against.
PyObject	indicator	The indicator to receive data from the consolidator.
*Nullable<TimeSpan>	resolution	*(Optional)* The resolution at which to send data to the indicator, None to use the same resolution as the subscription.
*PyObject	selector	*(Optional)* Selects a value from the BaseData send into the indicator, if None defaults to a cast (x => (T)x).

Return

Void - This method provides no return.

Definition at line 560 of file Algorithm/QCAlgorithm.Python.cs.

INDICATORS CONSOLIDATING DATA

RegisterIndicator() 3/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
PyObject indicator,
PyObject pyObject,
*PyObject selector
)
```

Registers the consolidator to receive automatic updates as well as configures the indicator to receive updates from the consolidator.

Show Details

Parameters		
Symbol	symbol	The symbol to register against.
PyObject	indicator	The indicator to receive data from the consolidator.
PyObject	pyObject	The python object that it is trying to register with, could be consolidator or a timespan.
*PyObject	selector	*(Optional)* Selects a value from the BaseData send into the indicator, if None defaults to a cast (x => (T)x).

Return

Void - This method provides no return.

Definition at line 575 of file Algorithm/QCAlgorithm.Python.cs.

INDICATORS CONSOLIDATING DATA

RegisterIndicator() 4/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
PyObject indicator,
IDataConsolidator consolidator,
*PyObject selector
)
```

Registers the consolidator to receive automatic updates as well as configures the indicator to receive updates from the consolidator.

Show Details

Parameters		
Symbol	symbol	The symbol to register against.
PyObject	indicator	The indicator to receive data from the consolidator.
IDataConsolidator	consolidator	The consolidator to receive raw subscription data.
*PyObject	selector	*(Optional)* Selects a value from the BaseData send into the indicator, if None defaults to a cast (x => (T)x).

Return

Void - This method provides no return.

Definition at line 624 of file Algorithm/QCAlgorithm.Python.cs.

CONSOLIDATING DATA INDICATORS

RegisterIndicator() 5/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
IndicatorBase<IndicatorDataPoint> indicator,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Show Details

Parameters		
Symbol	symbol	/
IndicatorBase<IndicatorDataPoint>	indicator	/
*Nullable<Resolution>	resolution	*(Optional)* /
*Func<IBaseData, Decimal>	selector	*(Optional)* /

Return

Void - This method provides no return.

Definition at line 2224 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA INDICATORS

RegisterIndicator() 6/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
IndicatorBase<IndicatorDataPoint> indicator,
*Nullable<TimeSpan> resolution,
*Func<IBaseData, Decimal> selector
)
```

Show Details

Parameters		
Symbol	symbol	/
IndicatorBase<IndicatorDataPoint>	indicator	/
*Nullable<TimeSpan>	resolution	*(Optional)* /
*Func<IBaseData, Decimal>	selector	*(Optional)* /

Return

Void - This method provides no return.

Definition at line 2239 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA INDICATORS

RegisterIndicator() 7/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
IndicatorBase<IndicatorDataPoint> indicator,
IDataConsolidator consolidator,
*Func<IBaseData, Decimal> selector
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`IndicatorBase<IndicatorDataPoint>`	indicator	/
`IDataConsolidator`	consolidator	/
`*Func<IBaseData, Decimal>`	selector	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 2254 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA INDICATORS

RegisterIndicator() 8/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
IndicatorBase<T> indicator,
*Nullable<Resolution> resolution
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`IndicatorBase<T>`	indicator	/
`*Nullable<Resolution>`	resolution	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 2279 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA INDICATORS

RegisterIndicator() 9/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
IndicatorBase<T> indicator,
Nullable<Resolution> resolution,
Func<IBaseData, T> selector
)
```

Show Details

Parameters		
Symbol	symbol	/
IndicatorBase<T>	indicator	/
Nullable<Resolution>	resolution	/
Func<IBaseData, T>	selector	/

Return

Void - This method provides no return.

Definition at line 2295 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA INDICATORS

RegisterIndicator() 10/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
Symbol symbol,
IndicatorBase<T> indicator,
Nullable<TimeSpan> resolution,
*Func<IBaseData, T> selector
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`IndicatorBase<T>`	indicator	/
`Nullable<TimeSpan>`	resolution	/
`*Func<IBaseData, T>`	selector	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 2311 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA INDICATORS

RegisterIndicator() 11/11

```
Void QuantConnect.Algorithm.QCAlgorithm.RegisterIndicator (
 Symbol symbol,
 IndicatorBase<T> indicator,
 IDataConsolidator consolidator,
 *Func<IBaseData, T> selector
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`IndicatorBase<T>`	indicator	/
`IDataConsolidator`	consolidator	/
`*Func<IBaseData, T>`	selector	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 2327 of file Algorithm/QCAlgorithm.Indicators.cs.

ADDING DATA

RemoveOptionContract() 1/1

```
Boolean QuantConnect.Algorithm.QCAlgorithm.RemoveOptionContract (
 Symbol symbol
)
```

Removes the security with the specified symbol. This will cancel all open orders and then liquidate any existing holdings.

Show Details

Parameters		
Symbol	symbol	The symbol of the security to be removed.

Return

Boolean - The new Boolean object.

Definition at line 2225 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

RemoveSecurity() 1/1

```
Boolean QuantConnect.Algorithm.QCAlgorithm.RemoveSecurity (
 Symbol symbol
)
```

Removes the security with the specified symbol. This will cancel all open orders and then liquidate any existing holdings.

Show Details

Parameters		
Symbol	symbol	The symbol of the security to be removed.

Return

`Boolean` - The new `Boolean` object.

Definition at line 2236 of file Algorithm/QCAlgorithm.cs.

CONSOLIDATING DATA | INDICATORS

ResolveConsolidator() 1/2

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.ResolveConsolidator (
Symbol symbol,
Nullable<Resolution> resolution,
*Type dataType
)
```

Gets the default consolidator for the specified symbol and resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose data is to be consolidated.
`Nullable<Resolution>`	resolution	The resolution for the consolidator, if None, uses the resolution from subscription.
`*Type`	dataType	*(Optional)* The data type for this consolidator, if None, uses TradeBar over QuoteBar if present.

Return

`IDataConsolidator` - The new default consolidator.

Definition at line 2550 of file Algorithm/QCAlgorithm.Indicators.cs.

CONSOLIDATING DATA | INDICATORS

ResolveConsolidator() 2/2

```
IDataConsolidator QuantConnect.Algorithm.QCAlgorithm.ResolveConsolidator (
Symbol symbol,
Nullable<TimeSpan> timeSpan,
*Type dataType
)
```

Gets the default consolidator for the specified symbol and resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose data is to be consolidated.
`Nullable<TimeSpan>`	timeSpan	The requested time span for the consolidator, if None, uses the resolution from subscription.
`*Type`	dataType	*(Optional)* The data type for this consolidator, if None, uses TradeBar over QuoteBar if present.

Return

`IDataConsolidator` - The new default consolidator.

Definition at line 2569 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

RMA() 1/1

```
RelativeMovingAverage QuantConnect.Algorithm.QCAlgorithm.RMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Relative Moving Average indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose relative moving average we seek.
`Int32`	period	The period of the relative moving average.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RelativeMovingAverage` - A relative moving average configured with the specified period and number of standard deviation.

Definition at line 1336 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ROC() 1/1

```
RateOfChange QuantConnect.Algorithm.QCAlgorithm.ROC (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RateOfChange indicator. This will compute the n-period rate of change in the security. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose RateOfChange we want.
Int32	period	The period over which to compute the RateOfChange.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RateOfChange` - The RateOfChange indicator for the requested symbol over the specified period.

Definition at line 1356 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ROCP() 1/1

```
RateOfChangePercent QuantConnect.Algorithm.QCAlgorithm.ROCP (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RateOfChangePercent indicator. This will compute the n-period percentage rate of change in the security. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose RateOfChangePercent we want.
Int32	period	The period over which to compute the RateOfChangePercent.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

RateOfChangePercent - The RateOfChangePercent indicator for the requested symbol over the specified period.

Definition at line 1375 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ROCR() 1/1

```
RateOfChangeRatio QuantConnect.Algorithm.QCAlgorithm.ROCR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RateOfChangeRatio indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose ROCR we want.
Int32	period	The period over which to compute the ROCR.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RateOfChangeRatio` - The RateOfChangeRatio indicator for the requested symbol over the specified period.

Definition at line 1393 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

RSI() 1/1

```
RelativeStrengthIndex QuantConnect.Algorithm.QCAlgorithm.RSI (
Symbol symbol,
Int32 period,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RelativeStrengthIndex indicator. This will produce an oscillator that ranges from 0 to 100 based on the ratio of average gains to average losses over the specified period.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RSI we want.
`Int32`	period	The period over which to compute the RSI.
`*MovingAverageType`	movingAverageType	*(Optional)* The type of moving average to use in computing the average gain/loss values.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`RelativeStrengthIndex` - The RelativeStrengthIndex indicator for the requested symbol over the specified period.

Definition at line 1413 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

RVI() 1/1

```
RelativeVigorIndex QuantConnect.Algorithm.QCAlgorithm.RVI (
Symbol symbol,
Int32 period,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new RelativeVigorIndex indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose RVI we want.
`Int32`	period	The period over which to compute the RVI.
`*MovingAverageType`	movingAverageType	*(Optional)* The type of moving average to use.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`RelativeVigorIndex` - The RelativeVigorIndex indicator for the requested symbol over the specified period.

Definition at line 1431 of file Algorithm/QCAlgorithm.Indicators.cs.

HANDLING DATA SECURITIES AND PORTFOLIO

SEDOL() 1/2

```
Symbol QuantConnect.Algorithm.QCAlgorithm.SEDOL (
String sedol,
*Nullable<DateTime> tradingDate
)
```

Converts a SEDOL identifier into a `Symbol` .

Show Details

Parameters		
`String`	sedol	The SEDOL identifier of an asset.
`*Nullable< DateTime>`	tradingDate	*(Optional)* The date that the stock being looked up is/was traded at. The date is used to create a Symbol with the ticker set to the ticker the asset traded under on the trading date. .

Return

`Symbol` - Symbol corresponding to the SEDOL. If no Symbol with a matching SEDOL was found, returns None.

Definition at line 2984 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA SECURITIES AND PORTFOLIO

SEDOL() 2/2

```
String QuantConnect.Algorithm.QCAlgorithm.SEDOL (
Symbol symbol
)
```

Converts a `Symbol` into a SEDOL identifier.

Show Details

Parameters		
`Symbol`	symbol	The `Symbol` .

Return

`String` - SEDOL corresponding to the Symbol. If no matching SEDOL is found, returns None.

Definition at line 2996 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS

Sell() 1/5

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Sell (
 Symbol symbol,
 Int32 quantity
)
```

Sell stock (alias of Order).

Show Details

Parameters		
`Symbol`	symbol	string Symbol of the asset to trade.
`Int32`	quantity	int Quantity of the asset to trade.

Return

`OrderTicket` - The order ticket instance.

Definition at line 102 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Sell() 2/5

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Sell (
 Symbol symbol,
 Double quantity
)
```

Sell stock (alias of Order).

Show Details

Parameters		
Symbol	symbol	String symbol to sell.
Double	quantity	Quantity to order.

Return

OrderTicket - The order ticket instance.

Definition at line 114 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Sell() 3/5

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Sell (
 Symbol symbol,
 Single quantity
)
```

Sell stock (alias of Order).

Show Details

Parameters		
Symbol	symbol	String symbol.
Single	quantity	Quantity to sell.

Return

OrderTicket - The order ticket instance.

Definition at line 126 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Sell() 4/5

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.Sell (
Symbol symbol,
Decimal quantity
)
```

Sell stock (alias of Order).

Show Details

Parameters		
Symbol	symbol	String symbol to sell.
Decimal	quantity	Quantity to sell.

Return

OrderTicket - The order ticket instance.

Definition at line 138 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

Sell() 5/5

```
IEnumerable<OrderTicket> QuantConnect.Algorithm.QCAlgorithm.Sell (
OptionStrategy strategy,
Int32 quantity,
*Boolean asynchronous,
*String tag,
*IOrderProperties orderProperties
)
```

Sell Option Strategy (alias of Order).

Show Details

Parameters		
`OptionStrategy`	strategy	Specification of the strategy to trade.
`Int32`	quantity	Quantity of the strategy to trade.
`*Boolean`	asynchronous	*(Optional)* Send the order asynchronously (False). Otherwise we'll block until it fills.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`IEnumerable<OrderTicket>` - Sequence of order tickets.

Definition at line 643 of file Algorithm/QCAlgorithm.Trading.cs.

SECURITIES AND PORTFOLIO

SetAccountCurrency() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetAccountCurrency (
 String accountCurrency
)
```

Sets the account currency cash symbol this algorithm is to manage.

Show Details

Parameters		
`String`	accountCurrency	The account currency cash symbol to set.

Return

`Void` - This method provides no return.

Definition at line 1327 of file Algorithm/QCAlgorithm.cs.

ALGORITHM FRAMEWORK

SetAlpha() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetAlpha (
IAlphaModel alpha
)
```

Sets the alpha model.

Show Details

Parameters		
IAlphaModel	alpha	Model that generates alpha.

Return

Void - This method provides no return.

Definition at line 316 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK

SetAlpha() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetAlpha (
PyObject alpha
)
```

Sets the alpha model.

Show Details

Parameters		
PyObject	alpha	Model that generates alpha.

Return

Void - This method provides no return.

Definition at line 31 of file Algorithm/QCAlgorithm.Framework.Python.cs.

HANDLING DATA

SetApi() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetApi (
IApi api
)
```

Provide the API for the algorithm.

Show Details

Parameters		
IApi	api	Initiated API.

Return

`Void` - This method provides no return.

Definition at line 2818 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS SECURITIES AND PORTFOLIO INDICATORS

SetBenchmark() 1/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBenchmark (
PyObject benchmark
)
```

Sets the specified function as the benchmark, this function provides the value of the benchmark at each date/time requested.

Show Details

Parameters		
PyObject	benchmark	The benchmark producing function.

Return

Void - This method provides no return.

Definition at line 1101 of file Algorithm/QCAlgorithm.Python.cs.

TRADING AND ORDERS | SECURITIES AND PORTFOLIO | INDICATORS

SetBenchmark() 2/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBenchmark (
 SecurityType securityType,
 String symbol
)
```

Sets the benchmark used for computing statistics of the algorithm to the specified symbol.

Show Details

Parameters		
SecurityType	securityType	Is the symbol an equity, forex, base, etc. Default SecurityType.Equity.
String	symbol	symbol to use as the benchmark.

Return

Void - This method provides no return.

Definition at line 1218 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS | SECURITIES AND PORTFOLIO | INDICATORS

SetBenchmark() 3/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBenchmark (
 String ticker
)
```

Sets the benchmark used for computing statistics of the algorithm to the specified ticker, defaulting to SecurityType.Equity if the ticker doesn't exist in the algorithm.

Show Details

Parameters		
String	ticker	Ticker to use as the benchmark.

Return

Void - This method provides no return.

Definition at line 1246 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS SECURITIES AND PORTFOLIO INDICATORS

SetBenchmark() 4/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBenchmark (
 Symbol symbol
)
```

Sets the benchmark used for computing statistics of the algorithm to the specified symbol.

Show Details

Parameters		
Symbol	symbol	symbol to use as the benchmark.

Return

Void - This method provides no return.

Definition at line 1275 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS SECURITIES AND PORTFOLIO INDICATORS

SetBenchmark() 5/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBenchmark (
Func<DateTime, Decimal> benchmark
)
```

Sets the specified function as the benchmark, this function provides the value of the benchmark at each date/time requested.

Show Details

Parameters		
`Func<DateTime, Decimal>`	benchmark	The benchmark producing function.

Return

`Void` - This method provides no return.

Definition at line 1294 of file Algorithm/QCAlgorithm.cs.

MODELING LOGGING

SetBrokerageMessageHandler() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBrokerageMessageHandler (
IBrokerageMessageHandler handler
)
```

Sets the implementation used to handle messages from the brokerage. The default implementation will forward messages to debug or error and when a `Error` occurs, the algorithm is stopped.

Show Details

Parameters		
`IBrokerageMessageHandler`	handler	The message handler to use.

Return

`Void` - This method provides no return.

Definition at line 1202 of file Algorithm/QCAlgorithm.cs.

MODELING

SetBrokerageModel() 1/3

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBrokerageModel (
PyObject model
)
```

Sets the brokerage to emulate in backtesting or paper trading. This can be used to set a custom brokerage model.

Show Details

Parameters		
PyObject	model	The brokerage model to use.

Return

Void - This method provides no return.

Definition at line 1123 of file Algorithm/QCAlgorithm.Python.cs.

MODELING

SetBrokerageModel() 2/3

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBrokerageModel (
BrokerageName brokerage,
*AccountType accountType
)
```

Sets the brokerage to emulate in backtesting or paper trading. This can be used for brokerages that have been implemented in LEAN.

Show Details

Parameters		
BrokerageName	brokerage	The brokerage to emulate. *Options: ['Default', 'QuantConnectBrokerage', 'InteractiveBrokersBrokerage', 'TradierBrokerage', 'OandaBrokerage', 'FxcmBrokerage', 'Bitfinex', 'Binance', 'GDAX', 'Alpaca', 'AlphaStreams', 'Zerodha', 'Samco', 'Atreyu', 'TradingTechnologies', 'Kraken', 'FTX', 'FTXUS', 'Exante', 'BinanceUS', 'Wolverine', 'TDAmeritrade', 'BinanceFutures', 'BinanceCoinFutures', 'RBI']*
*AccountType	accountType	*(Optional)* The account type (Cash or Margin). *Options: ['Margin', 'Cash']*

Return

Void - This method provides no return.

Definition at line 1157 of file Algorithm/QCAlgorithm.cs.

MODELING

SetBrokerageModel() 3/3

```
Void QuantConnect.Algorithm.QCAlgorithm.SetBrokerageModel (
 IBrokerageModel model
)
```

Sets the brokerage to emulate in backtesting or paper trading. This can be used to set a custom brokerage model.

Show Details

Parameters		
IBrokerageModel	model	The brokerage model to use.

Return

Void - This method provides no return.

Definition at line 1168 of file Algorithm/QCAlgorithm.cs.

SECURITIES AND PORTFOLIO

SetCash() 1/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetCash (
Int32 startingCash
)
```

Set initial cash for the strategy while backtesting. During live mode this value is ignored and replaced with the actual cash of your brokerage account.

Show Details

Parameters		
Int32	startingCash	Starting cash for the strategy backtest.

Return

Void - This method provides no return.

Definition at line 1359 of file Algorithm/QCAlgorithm.cs.

SECURITIES AND PORTFOLIO

SetCash() 2/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetCash (
Decimal startingCash
)
```

Set initial cash for the strategy while backtesting. During live mode this value is ignored and replaced with the actual cash of your brokerage account.

Show Details

Parameters		
Decimal	startingCash	Starting cash for the strategy backtest.

Return

Void - This method provides no return.

Definition at line 1370 of file Algorithm/QCAlgorithm.cs.

SECURITIES AND PORTFOLIO

SetCash() 3/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetCash (
String symbol,
Decimal startingCash,
*Decimal conversionRate
)
```

Set the cash for the specified symbol.

Show Details

Parameters		
String	symbol	The cash symbol to set.
Decimal	startingCash	Decimal cash value of portfolio.
*Decimal	conversionRate	*(Optional)* The current conversion rate for the.

Return

Void - This method provides no return.

Definition at line 1389 of file Algorithm/QCAlgorithm.cs.

SECURITIES AND PORTFOLIO

SetCash() 4/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetCash (
Double startingCash
)
```

Set initial cash for the strategy while backtesting. During live mode this value is ignored and replaced with the actual cash of your brokerage account.

Show Details

Parameters		
Double	startingCash	Starting cash for the strategy backtest.

Return

Void - This method provides no return.

Definition at line 1347 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

SetCurrentSlice() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetCurrentSlice (
Slice slice
)
```

Sets the current slice.

Show Details

Parameters		
Slice	slice	The Slice object.

Return

Void - This method provides no return.

Definition at line 2807 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

SetEndDate() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetEndDate (
Int32 year,
Int32 month,
Int32 day
)
```

Set the end date for a backtest run.

Show Details

Parameters		
Int32	year	Int year end date.
Int32	month	Int month end date.
Int32	day	Int end date 1-30.

Return

Void - This method provides no return.

Definition at line 1438 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

SetEndDate() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetEndDate (
DateTime end
)
```

Set the end date for a backtest.

Show Details

Parameters		
DateTime	end	Datetime value for end date.

Return

Void - This method provides no return.

Definition at line 1514 of file Algorithm/QCAlgorithm.cs.

ALGORITHM FRAMEWORK TRADING AND ORDERS

SetExecution() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetExecution (
IExecutionModel execution
)
```

Sets the execution model.

Show Details

Parameters		
IExecutionModel	execution	Model defining how to execute trades to reach a portfolio target.

Return

Void - This method provides no return.

Definition at line 362 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK TRADING AND ORDERS

SetExecution() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetExecution (
PyObject execution
)
```

Sets the execution model.

Show Details

Parameters		
PyObject	execution	Model defining how to execute trades to reach a portfolio target.

Return

Void - This method provides no return.

Definition at line 67 of file Algorithm/QCAlgorithm.Framework.Python.cs.

ADDING DATA

SetFutureChainProvider() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetFutureChainProvider (
IFutureChainProvider futureChainProvider
)
```

Sets the future chain provider, used to get the list of future contracts for an underlying symbol.

Show Details

Parameters		
IFutureChainProvider	futureChainProvider	The future chain provider.

Return

Void - This method provides no return.

Definition at line 837 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS

SetHoldings() 1/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetHoldings (
List<PortfolioTarget> targets,
*Boolean liquidateExistingHoldings,
*String tag,
*IOrderProperties orderProperties
)
```

Sets holdings for a collection of targets. The implementation will order the provided targets executing first those that reduce a position, freeing margin.

Show Details

Parameters		
`List<PortfolioTarget>`	targets	The portfolio desired quantities as percentages.
`*Boolean`	liquidateExistingHoldings	*(Optional)* True will liquidate existing holdings.
`*String`	tag	*(Optional)* Tag the order with a short string.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`Void` - This method provides no return.

Definition at line 1155 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

SetHoldings() 2/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetHoldings (
Symbol symbol,
Double percentage,
*Boolean liquidateExistingHoldings,
*String tag,
*IOrderProperties orderProperties
)
```

Alias for SetHoldings to avoid the M-decimal errors.

Show Details

Parameters		
`Symbol`	symbol	string symbol we wish to hold.
`Double`	percentage	double percentage of holdings desired.
`*Boolean`	liquidateExistingHoldings	*(Optional)* liquidate existing holdings if necessary to hold this stock.
`*String`	tag	*(Optional)* Tag the order with a short string.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`Void` - This method provides no return.

Definition at line 1182 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

SetHoldings() 3/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetHoldings (
Symbol symbol,
Single percentage,
*Boolean liquidateExistingHoldings,
*String tag,
*IOrderProperties orderProperties
)
```

Alias for SetHoldings to avoid the M-decimal errors.

Show Details

Parameters		
`Symbol`	symbol	string symbol we wish to hold.
`Single`	percentage	float percentage of holdings desired.
`*Boolean`	liquidateExistingHoldings	*(Optional)* bool liquidate existing holdings if necessary to hold this stock.
`*String`	tag	*(Optional)* Tag the order with a short string.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`Void` - This method provides no return.

Definition at line 1197 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

SetHoldings() 4/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetHoldings (
Symbol symbol,
Int32 percentage,
*Boolean liquidateExistingHoldings,
*String tag,
*IOrderProperties orderProperties
)
```

Alias for SetHoldings to avoid the M-decimal errors.

Show Details

Parameters		
`Symbol`	symbol	string symbol we wish to hold.
`Int32`	percentage	float percentage of holdings desired.
`*Boolean`	liquidateExistingHoldings	*(Optional)* bool liquidate existing holdings if necessary to hold this stock.
`*String`	tag	*(Optional)* Tag the order with a short string.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`Void` - This method provides no return.

Definition at line 1212 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

SetHoldings() 5/5

```
Void QuantConnect.Algorithm.QCAlgorithm.SetHoldings (
Symbol symbol,
Decimal percentage,
*Boolean liquidateExistingHoldings,
*String tag,
*IOrderProperties orderProperties
)
```

Automatically place a market order which will set the holdings to between 100% or -100% of *PORTFOLIO VALUE*. E.g. SetHoldings("AAPL", 0.1); SetHoldings("IBM", -0.2); -> Sets portfolio as long 10% APPL and short 20% IBM E.g. SetHoldings("AAPL", 2); -> Sets apple to 2x leveraged with all our cash. If the market is closed, place a market on open order.

Show Details

Parameters		
`Symbol`	symbol	Symbol indexer.
`Decimal`	percentage	decimal fraction of portfolio to set stock.
`*Boolean`	liquidateExistingHoldings	*(Optional)* bool flag to clean all existing holdings before setting new faction.
`*String`	tag	*(Optional)* Tag the order with a short string.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`Void` - This method provides no return.

Definition at line 1230 of file Algorithm/QCAlgorithm.Trading.cs.

HANDLING DATA MACHINE LEARNING

SetObjectStore() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetObjectStore (
IObjectStore objectStore
)
```

Sets the object store.

Show Details

Parameters		
`IObjectStore`	objectStore	The object store.

Return

`Void` - This method provides no return.

Definition at line 2828 of file Algorithm/QCAlgorithm.cs.

ADDING DATA

SetOptionChainProvider() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetOptionChainProvider (
IOptionChainProvider optionChainProvider
)
```

Sets the option chain provider, used to get the list of option contracts for an underlying symbol.

Show Details

Parameters		
IOptionChainProvider	optionChainProvider	The option chain provider.

Return

Void - This method provides no return.

Definition at line 827 of file Algorithm/QCAlgorithm.cs.

<-- Missing documentation attribute for SetPandasConverter -->

PARAMETER AND OPTIMIZATION

SetParameters() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetParameters (
Dictionary<String, String> parameters
)
```

Show Details

Parameters		
Dictionary<String, String>	parameters	/

Return

Void - This method provides no return.

Definition at line 740 of file Algorithm/QCAlgorithm.cs.

ALGORITHM FRAMEWORK TRADING AND ORDERS

SetPortfolioConstruction() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetPortfolioConstruction (
IPortfolioConstructionModel portfolioConstruction
)
```

Sets the portfolio construction model.

Show Details

Parameters		
IPortfolioConstructionModel	portfolioConstruction	Model defining how to build a portfolio from insights.

Return

Void - This method provides no return.

Definition at line 351 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK TRADING AND ORDERS

SetPortfolioConstruction() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetPortfolioConstruction (
PyObject portfolioConstruction
)
```

Sets the portfolio construction model.

Show Details

Parameters		
PyObject	portfolioConstruction	Model defining how to build a portfolio from alphas.

Return

Void - This method provides no return.

Definition at line 86 of file Algorithm/QCAlgorithm.Framework.Python.cs.

LOGGING

SetQuit() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetQuit (
Boolean quit
)
```

Set the Quit flag property of the algorithm.

Show Details

Parameters		
Boolean	quit	Boolean quit state.

Return

Void - This method provides no return.

Definition at line 2628 of file Algorithm/QCAlgorithm.cs.

ALGORITHM FRAMEWORK TRADING AND ORDERS

SetRiskManagement() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetRiskManagement (
IRiskManagementModel riskManagement
)
```

Sets the risk management model.

Show Details

Parameters		
IRiskManagementModel	riskManagement	Model defining how risk is managed.

Return

Void - This method provides no return.

Definition at line 373 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK TRADING AND ORDERS

SetRiskManagement() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetRiskManagement (
 PyObject riskManagement
)
```

Sets the risk management model.

Show Details

Parameters		
PyObject	riskManagement	Model defining how risk is managed.

Return

Void - This method provides no return.

Definition at line 137 of file Algorithm/QCAlgorithm.Framework.Python.cs.

HANDLING DATA LIVE TRADING

SetRunTimeError() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetRunTimeError (
Exception exception
)
```

Set the runtime error.

Show Details

Parameters		
Exception	exception	Represents error that occur during execution.

Return

Void - This method provides no return.

Definition at line 2701 of file Algorithm/QCAlgorithm.cs.

CHARTING

SetRuntimeStatistic() 1/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetRuntimeStatistic (
String name,
String value
)
```

Set a runtime statistic for the algorithm. Runtime statistics are shown in the top banner of a live algorithm GUI.

Show Details

Parameters		
String	name	Name of your runtime statistic.
String	value	String value of your runtime statistic.

Return

Void - This method provides no return.

Definition at line 297 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

SetRuntimeStatistic() 2/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetRuntimeStatistic (
String name,
Decimal value
)
```

Set a runtime statistic for the algorithm. Runtime statistics are shown in the top banner of a live algorithm GUI.

Show Details

Parameters		
String	name	Name of your runtime statistic.
Decimal	value	Decimal value of your runtime statistic.

Return

Void - This method provides no return.

Definition at line 308 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

SetRuntimeStatistic() 3/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetRuntimeStatistic (
String name,
Int32 value
)
```

Set a runtime statistic for the algorithm. Runtime statistics are shown in the top banner of a live algorithm GUI.

Show Details

Parameters		
String	name	Name of your runtime statistic.
Int32	value	Int value of your runtime statistic.

Return

Void - This method provides no return.

Definition at line 319 of file Algorithm/QCAlgorithm.Plotting.cs.

CHARTING

SetRuntimeStatistic() 4/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetRuntimeStatistic (
String name,
Double value
)
```

Set a runtime statistic for the algorithm. Runtime statistics are shown in the top banner of a live algorithm GUI.

Show Details

Parameters		
String	name	Name of your runtime statistic.
Double	value	Double value of your runtime statistic.

Return

Void - This method provides no return.

Definition at line 330 of file Algorithm/QCAlgorithm.Plotting.cs.

ADDING DATA MODELING

SetSecurityInitializer() 1/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetSecurityInitializer (
PyObject securityInitializer
)
```

Sets the security initializer function, used to initialize/configure securities after creation.

Show Details

Parameters		
PyObject	securityInitializer	The security initializer function or class.

Return

Void - This method provides no return.

Definition at line 1139 of file Algorithm/QCAlgorithm.Python.cs.

ADDING DATA MODELING

SetSecurityInitializer() 2/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetSecurityInitializer (
ISecurityInitializer securityInitializer
)
```

Sets the security initializer, used to initialize/configure securities after creation. The initializer will be applied to all universes and manually added securities.

Show Details

Parameters		
ISecurityInitializer	securityInitializer	The security initializer.

Return

Void - This method provides no return.

Definition at line 778 of file Algorithm/QCAlgorithm.cs.

ADDING DATA MODELING

SetSecurityInitializer() 3/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetSecurityInitializer (
Action<Security, Boolean> securityInitializer
)
```

Show Details

Parameters		
Action<Security, Boolean>	securityInitializer	/

Return

Void - This method provides no return.

Definition at line 804 of file Algorithm/QCAlgorithm.cs.

ADDING DATA MODELING

SetSecurityInitializer() 4/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetSecurityInitializer (
Action<Security> securityInitializer
)
```

Show Details

Parameters		
Action<Security>	securityInitializer	/

Return

Void - This method provides no return.

Definition at line 816 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

SetStartDate() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetStartDate (
 Int32 year,
 Int32 month,
 Int32 day
)
```

Set the start date for backtest.

Show Details

Parameters		
Int32	year	Int year starting date.
Int32	month	Int month starting date.
Int32	day	Int starting date 1-30.

Return

Void - This method provides no return.

Definition at line 1412 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

SetStartDate() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetStartDate (
 DateTime start
)
```

Set the start date for the backtest.

Show Details

Parameters		
DateTime	start	Datetime Start date for backtest.

Return

Void - This method provides no return.

Definition at line 1473 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

SetTimeZone() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetTimeZone (
String timeZone
)
```

Sets the time zone of the Time property in the algorithm.

Show Details

Parameters		
String	timeZone	The desired time zone.

Return

Void - This method provides no return.

Definition at line 1099 of file Algorithm/QCAlgorithm.cs.

HANDLING DATA

SetTimeZone() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetTimeZone (
DateTimeZone timeZone
)
```

Sets the time zone of the `Time` property in the algorithm.

Show Details

Parameters		
`DateTimeZone`	timeZone	The desired time zone.

Return

`Void` - This method provides no return.

Definition at line 1119 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS

SetTradeBuilder() 1/1

```
Void QuantConnect.Algorithm.QCAlgorithm.SetTradeBuilder (
 ITradeBuilder tradeBuilder
)
```

Set the `ITradeBuilder` implementation to generate trades from executions and market price updates.

Show Details

Parameters		
`ITradeBuilder`	tradeBuilder	/

Return

`Void` - This method provides no return.

Definition at line 1580 of file Algorithm/QCAlgorithm.cs.

ALGORITHM FRAMEWORK UNIVERSES

SetUniverseSelection() 1/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetUniverseSelection (
IUniverseSelectionModel universeSelection
)
```

Sets the universe selection model.

Show Details

Parameters		
IUniverseSelectionModel	universeSelection	Model defining universes for the algorithm.

Return

Void - This method provides no return.

Definition at line 279 of file Algorithm/QCAlgorithm.Framework.cs.

ALGORITHM FRAMEWORK UNIVERSES

SetUniverseSelection() 2/2

```
Void QuantConnect.Algorithm.QCAlgorithm.SetUniverseSelection (
PyObject universeSelection
)
```

Sets the universe selection model.

Show Details

Parameters		
PyObject	universeSelection	Model defining universes for the algorithm.

Return

Void - This method provides no return.

Definition at line 105 of file Algorithm/QCAlgorithm.Framework.Python.cs.

HISTORICAL DATA

SetWarmUp() 1/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetWarmUp (
TimeSpan timeSpan
)
```

Sets the warm up period to the specified value.

Show Details

Parameters		
TimeSpan	timeSpan	The amount of time to warm up, this does not take into account market hours/weekends.

Return

Void - This method provides no return.

Definition at line 65 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

SetWarmUp() 2/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetWarmUp (
TimeSpan timeSpan,
Nullable<Resolution> resolution
)
```

Sets the warm up period to the specified value.

Show Details

Parameters		
TimeSpan	timeSpan	The amount of time to warm up, this does not take into account market hours/weekends.
Nullable<Resolution>	resolution	The resolution to request.

Return

Void - This method provides no return.

Definition at line 87 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

SetWarmUp() 3/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetWarmUp (
Int32 barCount
)
```

Sets the warm up period by resolving a start date that would send that amount of data into the algorithm. The highest (smallest) resolution in the securities collection will be used. For example, if an algorithm has minute and daily data and 200 bars are requested, that would use 200 minute bars.

Show Details

Parameters		
Int32	barCount	The number of data points requested for warm up.

Return

Void - This method provides no return.

Definition at line 113 of file Algorithm/QCAlgorithm.History.cs.

HISTORICAL DATA

SetWarmUp() 4/4

```
Void QuantConnect.Algorithm.QCAlgorithm.SetWarmUp (
Int32 barCount,
Nullable<Resolution> resolution
)
```

Sets the warm up period by resolving a start date that would send that amount of data into the algorithm.

Show Details

Parameters		
Int32	barCount	The number of data points requested for warm up.
Nullable<Resolution>	resolution	The resolution to request.

Return

Void - This method provides no return.

Definition at line 137 of file Algorithm/QCAlgorithm.History.cs.

TRADING AND ORDERS

Shortable() 1/2

```
Boolean QuantConnect.Algorithm.QCAlgorithm.Shortable (
Symbol symbol
)
```

Determines if the Symbol is shortable at the brokerage.

Show Details

Parameters		
Symbol	symbol	Symbol to check if shortable.

Return

Boolean - True if shortable.

Definition at line 2840 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS

Shortable() 2/2

```
Boolean QuantConnect.Algorithm.QCAlgorithm.Shortable (
 Symbol symbol,
 Decimal shortQuantity
)
```

Determines if the Symbol is shortable at the brokerage.

Show Details

Parameters		
Symbol	symbol	Symbol to check if shortable.
Decimal	shortQuantity	Order's quantity to check if it is currently shortable, taking into account current holdings and open orders.

Return

Boolean - True if shortable.

Definition at line 2852 of file Algorithm/QCAlgorithm.cs.

TRADING AND ORDERS

ShortableQuantity() 1/1

```
Int64 QuantConnect.Algorithm.QCAlgorithm.ShortableQuantity (
 Symbol symbol
)
```

Gets the quantity shortable for the given asset.

Show Details

Parameters		
`Symbol`	symbol	/

Return

`Int64` - Quantity shortable for the given asset. Zero if not shortable, or a number greater than zero if shortable.

Definition at line 2881 of file Algorithm/QCAlgorithm.cs.

INDICATORS

SI() 1/1

```
WilderSwingIndex QuantConnect.Algorithm.QCAlgorithm.SI (
Symbol symbol,
Decimal limitMove,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a Wilder Swing Index (SI) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose SI we want.
`Decimal`	limitMove	The maximum daily change in price for the SI.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`WilderSwingIndex` - The WilderSwingIndex for the given parameters.

Definition at line 1906 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

SMA() 1/1

```
SimpleMovingAverage QuantConnect.Algorithm.QCAlgorithm.SMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates an SimpleMovingAverage indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose SMA we want.
`Int32`	period	The period of the SMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`SimpleMovingAverage` - The SimpleMovingAverage for the given parameters.

Definition at line 1528 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

SORTINO() 1/1

```
SortinoRatio QuantConnect.Algorithm.QCAlgorithm.SORTINO (
Symbol symbol,
Int32 sortinoPeriod,
*Double minimumAcceptableReturn,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Sortino indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Sortino we want.
`Int32`	sortinoPeriod	Period of historical observation for Sortino ratio calculation.
`*Double`	minimumAcceptableReturn	*(Optional)* Minimum acceptable return (eg risk-free rate) for the Sortino ratio calculation.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`SortinoRatio` - The SortinoRatio indicator for the requested symbol over the specified period.

Definition at line 1508 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

SR() 1/1

```
SharpeRatio QuantConnect.Algorithm.QCAlgorithm.SR (
Symbol symbol,
Int32 sharpePeriod,
*Decimal riskFreeRate,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new RollingSharpeRatio indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose RSR we want.
Int32	sharpePeriod	Period of historical observation for sharpe ratio calculation.
*Decimal	riskFreeRate	*(Optional)* Risk-free rate for sharpe ratio calculation.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

SharpeRatio - The RollingSharpeRatio indicator for the requested symbol over the specified period.

Definition at line 1489 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

STC() 1/1

```
SchaffTrendCycle QuantConnect.Algorithm.QCAlgorithm.STC (
 Symbol symbol,
 Int32 cyclePeriod,
 Int32 fastPeriod,
 Int32 slowPeriod,
 *MovingAverageType movingAverageType,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new Schaff Trend Cycle indicator.

Show Details

Parameters		
Symbol	symbol	The symbol for the indicator to track.
Int32	cyclePeriod	The signal period.
Int32	fastPeriod	The fast moving average period.
Int32	slowPeriod	The slow moving average period.
*MovingAverageType	movingAverageType	*(Optional)* The type of moving average to use.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

SchaffTrendCycle - The SchaffTrendCycle indicator for the requested symbol over the specified period.

Definition at line 1549 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

STD() 1/1

```
StandardDeviation QuantConnect.Algorithm.QCAlgorithm.STD (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a new StandardDeviation indicator. This will return the population standard deviation of samples over the specified period.

Show Details

Parameters		
Symbol	symbol	The symbol whose STD we want.
Int32	period	The period over which to compute the STD.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

StandardDeviation - The StandardDeviation indicator for the requested symbol over the specified period.

Definition at line 1567 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

STO() 1/2

```
Stochastic QuantConnect.Algorithm.QCAlgorithm.STO (
Symbol symbol,
Int32 period,
Int32 kPeriod,
Int32 dPeriod,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new Stochastic indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose stochastic we seek.
`Int32`	period	The period of the stochastic. Normally 14.
`Int32`	kPeriod	The sum period of the stochastic. Normally 14.
`Int32`	dPeriod	The sum period of the stochastic. Normally 3.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`Stochastic` - Stochastic indicator for the requested symbol.

Definition at line 1607 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

STO() 2/2

```
Stochastic QuantConnect.Algorithm.QCAlgorithm.STO (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, TradeBar> selector
)
```

Overload short hand to create a new Stochastic indicator; defaulting to the 3 period for dStoch.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose stochastic we seek.
`Int32`	period	The period of the stochastic. Normally 14.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`Stochastic` - Stochastic indicator for the requested symbol.

Definition at line 1626 of file Algorithm/QCAlgorithm.Indicators.cs.

TRADING AND ORDERS

StopLimitOrder() 1/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.StopLimitOrder (
Symbol symbol,
Int32 quantity,
Decimal stopPrice,
Decimal limitPrice,
*String tag,
*IOrderProperties orderProperties
)
```

Send a stop limit order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Int32`	quantity	Quantity of shares for limit order.
`Decimal`	stopPrice	Stop price for this order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 488 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

StopLimitOrder() 2/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.StopLimitOrder (
 Symbol symbol,
 Double quantity,
 Decimal stopPrice,
 Decimal limitPrice,
 *String tag,
 *IOrderProperties orderProperties
 )
```

Send a stop limit order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Double`	quantity	Quantity of shares for limit order.
`Decimal`	stopPrice	Stop price for this order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 504 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

StopLimitOrder() 3/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.StopLimitOrder (
 Symbol symbol,
 Decimal quantity,
 Decimal stopPrice,
 Decimal limitPrice,
 *String tag,
 *IOrderProperties orderProperties
 )
```

Send a stop limit order to the transaction handler:.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset.
`Decimal`	quantity	Quantity of shares for limit order.
`Decimal`	stopPrice	Stop price for this order.
`Decimal`	limitPrice	Limit price to fill this order.
`*String`	tag	*(Optional)* String tag for the order (optional).
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 520 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

StopMarketOrder() 1/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.StopMarketOrder (
Symbol symbol,
Int32 quantity,
Decimal stopPrice,
*String tag,
*IOrderProperties orderProperties
)
```

Create a stop market order and return the newly created order id; or negative if the order is invalid.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset we're trading.
`Int32`	quantity	Quantity to be traded.
`Decimal`	stopPrice	Price to fill the stop order.
`*String`	tag	*(Optional)* Optional string data tag for the order.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 439 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

StopMarketOrder() 2/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.StopMarketOrder (
Symbol symbol,
Double quantity,
Decimal stopPrice,
*String tag,
*IOrderProperties orderProperties
)
```

Create a stop market order and return the newly created order id; or negative if the order is invalid.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset we're trading.
`Double`	quantity	Quantity to be traded.
`Decimal`	stopPrice	Price to fill the stop order.
`*String`	tag	*(Optional)* Optional string data tag for the order.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 454 of file Algorithm/QCAlgorithm.Trading.cs.

TRADING AND ORDERS

StopMarketOrder() 3/3

```
OrderTicket QuantConnect.Algorithm.QCAlgorithm.StopMarketOrder (
Symbol symbol,
Decimal quantity,
Decimal stopPrice,
*String tag,
*IOrderProperties orderProperties
)
```

Create a stop market order and return the newly created order id; or negative if the order is invalid.

Show Details

Parameters		
`Symbol`	symbol	String symbol for the asset we're trading.
`Decimal`	quantity	Quantity to be traded.
`Decimal`	stopPrice	Price to fill the stop order.
`*String`	tag	*(Optional)* Optional string data tag for the order.
`*IOrderProperties`	orderProperties	*(Optional)* The order properties to use. Defaults to `DefaultOrderProperties` .

Return

`OrderTicket` - The order ticket instance.

Definition at line 469 of file Algorithm/QCAlgorithm.Trading.cs.

INDICATORS

STR() 1/1

```
SuperTrend QuantConnect.Algorithm.QCAlgorithm.STR (
Symbol symbol,
Int32 period,
Decimal multiplier,
*MovingAverageType movingAverageType,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new SuperTrend indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose SuperTrend indicator we want.
`Int32`	period	The smoothing period for average True range.
`Decimal`	multiplier	Multiplier to calculate basic upper and lower bands width.
`*MovingAverageType`	movingAverageType	*(Optional)* Smoother type for average True range, defaults to Wilders.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`SuperTrend` - The new `SuperTrend` object.

Definition at line 1469 of file Algorithm/QCAlgorithm.Indicators.cs.

<-- Missing documentation attribute for SubmitOrderRequest -->

INDICATORS

SUM() 1/1

```
Sum QuantConnect.Algorithm.QCAlgorithm.SUM (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Sum indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Sum we want.
`Int32`	period	The period over which to compute the Sum.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`Sum` - The Sum indicator for the requested symbol over the specified period.

Definition at line 1640 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

SWISS() 1/1

```
SwissArmyKnife QuantConnect.Algorithm.QCAlgorithm.SWISS (
Symbol symbol,
Int32 period,
Double delta,
SwissArmyKnifeTool tool,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates Swiss Army Knife transformation for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol to use for calculations.
`Int32`	period	The period of the calculation.
`Double`	delta	The delta scale of the BandStop or BandPass.
`SwissArmyKnifeTool`	tool	The tool os the Swiss Army Knife. *Options: ['Gauss', 'Butter', 'HighPass', 'TwoPoleHighPass', 'BandPass']*
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* elects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`SwissArmyKnife` - The calculation using the given tool.

Definition at line 1661 of file Algorithm/QCAlgorithm.Indicators.cs.

ADDING DATA HANDLING DATA

Symbol() 1/1

```
Symbol QuantConnect.Algorithm.QCAlgorithm.Symbol (
 String ticker
)
```

Converts the string 'ticker' symbol into a full `Symbol` object This requires that the string 'ticker' has been added to the algorithm.

Show Details

Parameters		
`String`	ticker	The ticker symbol. This should be the ticker symbol as it was added to the algorithm.

Return

`Symbol` - The symbol object mapped to the specified ticker.

Definition at line 2644 of file Algorithm/QCAlgorithm.cs.

INDICATORS

T3() 1/1

```
T3MovingAverage QuantConnect.Algorithm.QCAlgorithm.T3 (
Symbol symbol,
Int32 period,
*Decimal volumeFactor,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new T3MovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose T3 we want.
`Int32`	period	The period over which to compute the T3.
`*Decimal`	volumeFactor	*(Optional)* The volume factor to be used for the T3 (value must be in the [0,1] range, defaults to 0.7).
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`T3MovingAverage` - The T3MovingAverage indicator for the requested symbol over the specified period.

Definition at line 1680 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TDD() 1/1

```
TargetDownsideDeviation QuantConnect.Algorithm.QCAlgorithm.TDD (
Symbol symbol,
Int32 period,
*Double minimumAcceptableReturn,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new TargetDownsideDeviation indicator. The target downside deviation is defined as the root-mean-square, or RMS, of the deviations of the realized return's underperformance from the target return where all returns above the target return are treated as underperformance of 0.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TDD we want.
`Int32`	period	The period over which to compute the TDD.
`*Double`	minimumAcceptableReturn	*(Optional)* Minimum acceptable return (MAR) for the target downside deviation calculation.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`TargetDownsideDeviation` - The TargetDownsideDeviation indicator for the requested symbol over the specified period.

Definition at line 1587 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TEMA() 1/1

```
TripleExponentialMovingAverage QuantConnect.Algorithm.QCAlgorithm.TEMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new TripleExponentialMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TEMA we want.
`Int32`	period	The period over which to compute the TEMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`TripleExponentialMovingAverage` - The TripleExponentialMovingAverage indicator for the requested symbol over the specified period.

Definition at line 1698 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TP() 1/1

```
TimeProfile QuantConnect.Algorithm.QCAlgorithm.TP (
Symbol symbol,
*Int32 period,
*Decimal valueAreaVolumePercentage,
*Decimal priceRangeRoundOff,
*Resolution resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an Market Profile indicator for the symbol with Time Price Opportunity (TPO) mode. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TP we want.
`*Int32`	period	*(Optional)* The period of the TP.
`*Decimal`	valueAreaVolumePercentage	*(Optional)* The percentage of volume contained in the value area.
`*Decimal`	priceRangeRoundOff	*(Optional)* How many digits you want to round and the precision. i.e 0.01 round to two digits exactly.
`*Resolution`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`TimeProfile` - The Time Profile indicator for the given parameters.

Definition at line 998 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TR() 1/1

```
TrueRange QuantConnect.Algorithm.QCAlgorithm.TR (
Symbol symbol,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new TrueRange indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TR we want.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`TrueRange` - The TrueRange indicator for the requested symbol.

Definition at line 1738 of file Algorithm/QCAlgorithm.Indicators.cs.

MACHINE LEARNING SCHEDULED EVENTS

Train() 1/4

```
ScheduledEvent QuantConnect.Algorithm.QCAlgorithm.Train (
 PyObject trainingCode
)
```

Schedules the provided training code to execute immediately.

Show Details

Parameters		
`PyObject`	trainingCode	The training code to be invoked.

Return

`ScheduledEvent` - The new `ScheduledEvent` object.

Definition at line 1334 of file Algorithm/QCAlgorithm.Python.cs.

MACHINE LEARNING SCHEDULED EVENTS

Train() 2/4

```
ScheduledEvent QuantConnect.Algorithm.QCAlgorithm.Train (
IDateRule dateRule,
ITimeRule timeRule,
PyObject trainingCode
)
```

Schedules the training code to run using the specified date and time rules.

Show Details

Parameters		
IDateRule	dateRule	Specifies what dates the event should run.
ITimeRule	timeRule	Specifies the times on those dates the event should run.
PyObject	trainingCode	The training code to be invoked.

Return

ScheduledEvent - The new ScheduledEvent object.

Definition at line 1347 of file Algorithm/QCAlgorithm.Python.cs.

MACHINE LEARNING SCHEDULED EVENTS

Train() 3/4

```
ScheduledEvent QuantConnect.Algorithm.QCAlgorithm.Train (
Action trainingCode
)
```

Schedules the provided training code to execute immediately.

Show Details

Parameters		
Action	trainingCode	The training code to be invoked.

Return

`ScheduledEvent` - The new `ScheduledEvent` object.

Definition at line 2764 of file Algorithm/QCAlgorithm.cs.

MACHINE LEARNING SCHEDULED EVENTS

Train() 4/4

```
ScheduledEvent QuantConnect.Algorithm.QCAlgorithm.Train (
IDateRule dateRule,
ITimeRule timeRule,
Action trainingCode
)
```

Schedules the training code to run using the specified date and time rules.

Show Details

Parameters		
`IDateRule`	dateRule	Specifies what dates the event should run.
`ITimeRule`	timeRule	Specifies the times on those dates the event should run.
`Action`	trainingCode	The training code to be invoked.

Return

`ScheduledEvent` - The new `ScheduledEvent` object.

Definition at line 2777 of file Algorithm/QCAlgorithm.cs.

INDICATORS

TRIMA() 1/1

```
TriangularMovingAverage QuantConnect.Algorithm.QCAlgorithm.TRIMA (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new TriangularMovingAverage indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose TRIMA we want.
`Int32`	period	The period over which to compute the TRIMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`TriangularMovingAverage` - The TriangularMovingAverage indicator for the requested symbol over the specified period.

Definition at line 1756 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TRIN() 1/2

```
ArmsIndex QuantConnect.Algorithm.QCAlgorithm.TRIN (
IEnumerable<Symbol> symbols,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new Arms Index indicator.

Show Details

Parameters		
`IEnumerable<Symbol>`	symbols	/
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* /

Return

`ArmsIndex` - The new `ArmsIndex` object.

Definition at line 1945 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TRIN() 2/2

```
ArmsIndex QuantConnect.Algorithm.QCAlgorithm.TRIN (
Symbol> symbols,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates a new Arms Index indicator.

Show Details

Parameters		
`Symbol>`	symbols	The symbols whose Arms Index we want.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`ArmsIndex` - The Arms Index indicator for the requested symbol over the specified period.

Definition at line 1958 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TRIX() 1/1

```
Trix QuantConnect.Algorithm.QCAlgorithm.TRIX (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Trix indicator.

Show Details

Parameters		
Symbol	symbol	The symbol whose TRIX we want.
Int32	period	The period over which to compute the TRIX.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

Trix - The Trix indicator for the requested symbol over the specified period.

Definition at line 1774 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

TSI() 1/1

```
TrueStrengthIndex QuantConnect.Algorithm.QCAlgorithm.TSI (
Symbol symbol,
*Int32 longTermPeriod,
*Int32 shortTermPeriod,
*Int32 signalPeriod,
*MovingAverageType signalType,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a TrueStrengthIndex indicator for the symbol. The indicator will be automatically updated on the given

resolution.

Show Details

Parameters		
Symbol	symbol	The symbol whose TSI we want.
*Int32	longTermPeriod	*(Optional)* Period used for the second (double) price change smoothing.
*Int32	shortTermPeriod	*(Optional)* Period used for the first price change smoothing.
*Int32	signalPeriod	*(Optional)* The signal period.
*MovingAverageType	signalType	*(Optional)* The type of moving average to use for the signal.
*Nullable<Resolution>	resolution	*(Optional)* The resolution.
*Func<IBaseData, Decimal>	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

TrueStrengthIndex - The TrueStrengthIndex indicator for the given parameters.

Definition at line 1720 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

ULTOSC() 1/1

```
UltimateOscillator QuantConnect.Algorithm.QCAlgorithm.ULTOSC (
Symbol symbol,
Int32 period1,
Int32 period2,
Int32 period3,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new UltimateOscillator indicator.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose ULTOSC we want.
`Int32`	period1	The first period over which to compute the ULTOSC.
`Int32`	period2	The second period over which to compute the ULTOSC.
`Int32`	period3	The third period over which to compute the ULTOSC.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`UltimateOscillator` - The UltimateOscillator indicator for the requested symbol over the specified period.

Definition at line 1794 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

VAR() 1/1

```
Variance QuantConnect.Algorithm.QCAlgorithm.VAR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Creates a new Variance indicator. This will return the population variance of samples over the specified period.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VAR we want.
`Int32`	period	The period over which to compute the VAR.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`Variance` - The Variance indicator for the requested symbol over the specified period.

Definition at line 1812 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

VP() 1/1

```
VolumeProfile QuantConnect.Algorithm.QCAlgorithm.VP (
Symbol symbol,
*Int32 period,
*Decimal valueAreaVolumePercentage,
*Decimal priceRangeRoundOff,
*Resolution resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an Market Profile indicator for the symbol with Volume Profile (VOL) mode. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VP we want.
`*Int32`	period	*(Optional)* The period of the VP.
`*Decimal`	valueAreaVolumePercentage	*(Optional)* The percentage of volume contained in the value area.
`*Decimal`	priceRangeRoundOff	*(Optional)* How many digits you want to round and the precision. i.e 0.01 round to two digits exactly.
`*Resolution`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`VolumeProfile` - The Volume Profile indicator for the given parameters.

Definition at line 977 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

VWAP() 1/2

```
VolumeWeightedAveragePriceIndicator QuantConnect.Algorithm.QCAlgorithm.VWAP (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, TradeBar> selector
)
```

Creates an VolumeWeightedAveragePrice (VWAP) indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VWAP we want.
`Int32`	period	The period of the VWAP.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, TradeBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`VolumeWeightedAveragePriceIndicator` - The VolumeWeightedAveragePrice for the given parameters.

Definition at line 1831 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

VWAP() 2/2

```
IntradayVwap QuantConnect.Algorithm.QCAlgorithm.VWAP (
 Symbol symbol
)
```

Creates the canonical VWAP indicator that resets each day. The indicator will be automatically updated on the security's configured resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose VWAP we want.

Return

`IntradayVwap` - The IntradayVWAP for the specified symbol.

Definition at line 1847 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS HISTORICAL DATA

WarmUpIndicator() 1/5

```
Void QuantConnect.Algorithm.QCAlgorithm.WarmUpIndicator (
Symbol symbol,
PyObject indicator,
*Nullable<Resolution> resolution,
*PyObject selector
)
```

Warms up a given indicator with historical data.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose indicator we want.
`PyObject`	indicator	The indicator we want to warm up.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*PyObject`	selector	*(Optional)* Selects a value from the BaseData send into the indicator, if None defaults to a cast (x => (T)x).

Return

`Void` - This method provides no return.

Definition at line 659 of file Algorithm/QCAlgorithm.Python.cs.

HISTORICAL DATA INDICATORS

WarmUpIndicator() 2/5

```
Void QuantConnect.Algorithm.QCAlgorithm.WarmUpIndicator (
Symbol symbol,
IndicatorBase<IndicatorDataPoint> indicator,
*Nullable<Resolution> resolution,
*Func<IBaseData, Decimal> selector
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`IndicatorBase<IndicatorDataPoint>`	indicator	/
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Func<IBaseData, Decimal>`	selector	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 2371 of file Algorithm/QCAlgorithm.Indicators.cs.

HISTORICAL DATA INDICATORS

WarmUpIndicator() 3/5

```
Void QuantConnect.Algorithm.QCAlgorithm.WarmUpIndicator (
 Symbol symbol,
 IndicatorBase<IndicatorDataPoint> indicator,
 TimeSpan period,
 *Func<IBaseData, Decimal> selector
 )
```

Show Details

Parameters		
`Symbol`	symbol	/
`IndicatorBase<IndicatorDataPoint>`	indicator	/
`TimeSpan`	period	/
`*Func<IBaseData, Decimal>`	selector	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 2387 of file Algorithm/QCAlgorithm.Indicators.cs.

HISTORICAL DATA INDICATORS

WarmUpIndicator() 4/5

```
Void QuantConnect.Algorithm.QCAlgorithm.WarmUpIndicator (
Symbol symbol,
IndicatorBase<T> indicator,
*Nullable<Resolution> resolution,
*Func<IBaseData, T> selector
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`IndicatorBase<T>`	indicator	/
`*Nullable<Resolution>`	resolution	*(Optional)* /
`*Func<IBaseData, T>`	selector	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 2413 of file Algorithm/QCAlgorithm.Indicators.cs.

HISTORICAL DATA INDICATORS

WarmUpIndicator() 5/5

```
Void QuantConnect.Algorithm.QCAlgorithm.WarmUpIndicator (
Symbol symbol,
IndicatorBase<T> indicator,
TimeSpan period,
*Func<IBaseData, T> selector
)
```

Show Details

Parameters		
`Symbol`	symbol	/
`IndicatorBase<T>`	indicator	/
`TimeSpan`	period	/
`*Func<IBaseData, T>`	selector	*(Optional)* /

Return

`Void` - This method provides no return.

Definition at line 2430 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

WILR() 1/1

```
WilliamsPercentR QuantConnect.Algorithm.QCAlgorithm.WILR (
Symbol symbol,
Int32 period,
*Nullable<Resolution> resolution,
*Func<IBaseData, IBaseDataBar> selector
)
```

Creates a new Williams %R indicator. This will compute the percentage change of the current closing price in relation to the high and low of the past N periods. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose Williams %R we want.
`Int32`	period	The period over which to compute the Williams %R.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, IBaseDataBar>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to casting the input value to a TradeBar.

Return

`WilliamsPercentR` - The Williams %R indicator for the requested symbol over the specified period.

Definition at line 1866 of file Algorithm/QCAlgorithm.Indicators.cs.

INDICATORS

WWMA() 1/1

```
WilderMovingAverage QuantConnect.Algorithm.QCAlgorithm.WWMA (
 Symbol symbol,
 Int32 period,
 *Nullable<Resolution> resolution,
 *Func<IBaseData, Decimal> selector
)
```

Creates a WilderMovingAverage indicator for the symbol. The indicator will be automatically updated on the given resolution.

Show Details

Parameters		
`Symbol`	symbol	The symbol whose WMA we want.
`Int32`	period	The period of the WMA.
`*Nullable<Resolution>`	resolution	*(Optional)* The resolution.
`*Func<IBaseData, Decimal>`	selector	*(Optional)* Selects a value from the BaseData to send into the indicator, if None defaults to the Value property of BaseData (x => x.Value).

Return

`WilderMovingAverage` - The WilderMovingAverage for the given parameters.

Definition at line 1886 of file Algorithm/QCAlgorithm.Indicators.cs.

Migrations

Migrations

Zipline

The following pages explain how to migrate trading algorithms from Zipline to LEAN:

Initialization

Using Data

Ordering

Logging and Plotting

Quick Reference

Zipline

Initialization

Initializing State

On QuantConnect, algorithm initialization behavior is equivalent to Quantopian's `initialize` method. `Initialize` is the method equivalent, and it is only ran once at the start of the algorithm. It is responsible for initially adding data to the algorithm, adding a universe, setting the brokerage, setting the algorithm's start and end date, etc.

The algorithm structure in QuantConnect differs from Quantopian's as well. On QuantConnect, we create a class that derives from `QCAlgorithm` and define our overrides/algorithm functionality there. An example of an algorithm with initialization is provided.

Quantopian

```py
def initialize(context):
    # Adds AAPL sid to `context` for use later in `handle_data(...)`
    context.aapl = sid(24)
```

QuantConnect

```py
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        # Adds minutely AAPL data to the algorithm
        self.aapl = self.AddEquity("AAPL", Resolution.Minute)
```

On QuantConnect, the `self` parameter is the equivalent of the `context` parameter in Quantopian algorithms. You can use `self` to access algorithm resources, such as the Portfolio, Orders, Order Tickets, Securities, place orders in your algorithm, and much more.

You can read more about algorithm initialization at the Initializion documentation page.

Attaching Pipelines

The functional equivalent of Pipelines on QuantConnect are Universes. Universes can be used to dynamically select assets your algorithm wants to trade or request data from. To add a universe to your algorithm, you can call the `AddUniverse()` method and provide the required Coarse and Fine universe selection functions.

Coarse Universe selection is the first step of universe selection. It provides a means to filter data in a lightweight fashion before proceeding to Fine Universe selection. Coarse universe will allow you to filter assets based off top-level fundamental factors, such as Dollar Volume for the day, if a company has fundamental data, and market of the asset.

Fine Universe selection is the second step of universe selection. It provides fundamental data to your user-defined function, and can be used to filter in greater detail based on an asset's fundamental data, such as earnings, EPS, etc.

An example of coarse and fine universe selection to filter assets in our algorithm is provided. Adding universes can be used as an alternative to using `AddEquity` if you prefer dynamic asset selection.

```
class MyUniverseAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2020, 1, 1)
        self.SetEndDate(2020, 2, 1)

        self.UniverseSettings.Resolution = Resolution.Minute
        self.AddUniverse(self.CoarseSelectionFunction, self.FineSelectionFunction)

    def CoarseSelectionFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        return [i.Symbol for i in coarse if i.DollarVolume > 500000 and i.HasFundamentalData]

    def FineSelectionFunction(self, fine: List[FineFundamental]) -> List[Symbol]:
        return [i.Symbol for i in fine if i.EarningReports.BasicEPS.OneMonth > 0]
```

PY

You can configure universe settings by modifying the existing `UniverseSettings` attribute of the algorithm.

```
class MyUniverseAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.UniverseSettings.Resolution = Resolution.Minute
        self.UniverseSettings.DataNormalizationMode = DataNormalizationMode.Adjusted
        self.UniverseSettings.Leverage = 1.0
        self.UniverseSettings.ExtendedMarketHours = False
```

PY

You can read more about universe selection at the Universe documentation page.

Scheduling Functions

Scheduled Events on QuantConnect are the equivalent of `schedule_function()` from Quantopian. Examples are provided comparing the Scheduled Events functionality between QuantConnect and Quantopian.

Quantopian

```
import quantopian.algorithm as algo

def my_scheduled_function(context, data):
    pass

def initialize(context):
    # Runs a function every day 60 minutes before U.S. Equities market close
    algo.schedule_function(
        func=my_scheduled_function,
        date_rule=algo.date_rules.every_day(),
        time_rule=algo.time_rules.market_close(minutes=60),
        calendar=algo.calendars.US_EQUITIES
    )
```

PY

QuantConnect

```
class MyAlgorithm(QCAlgorithm):
    def my_scheduled_function(self):
        pass

    # Runs a function every day 60 minutes before SPY ETF's market close
    def Initialize(self) -> None:
        self.Schedule.On(
            self.DateRules.EveryDay(),
            self.TimeRules.BeforeMarketClose("SPY", 60),
            self.my_scheduled_function
       )
```

PY

You can read more about scheduled events at the Scheduled Events documentation page.

Setting Slippage and Commissions

QuantConnect supports applying slippage and commissions per individual security.

To add a slippage model to a security, we must set the `SlippageModel` property of the `Security` object to our model. A `Security` is returned when data is added to the algorithm. Examples of setting slippage in an algorithm is provided below for both Quantopian and QuantConnect.

Quantopian

```
import quantopian.algorithm as algorithm
from zipline.finance.slippage import FixedSlippage

    def initialize(context):
        # This will set slippage for all U.S. equities
        algorithm.set_slippage(us_equities=FixedSlippage(0.01))
```

PY

QuantConnect

```
class MyAlgorithm(QCAlgorithm)
    def Initialize(self) -> None:
        spy = self.AddEquity("SPY", Resolution.Minute)
        # `ConstantSlippageModel` is the same as `FixedSlippage` on Quantopian.
        # This will set slippage only for the "SPY" security.
        spy.SlippageModel = ConstantSlippageModel(0.01)
```

PY

Commissions

To add a fee model (otherwise known as Commissions on Quantopian) to a security, we must set the `FeeModel` property of the `Security` object to our model. Examples are provided below for Quantopian and QuantConnect.

Quantopian

```
import quantopian.algorithm as algorithm
from zipline.finance.commission import PerShare

    def initialize(context):
        # Approximates Interactive Brokers' equities trading commissions.
        algorithm.set_commission(us_equities=Pershare(cost=0.0075))
```

QuantConnect

```
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
       aapl = self.AddEquity("AAPL", Resolution.Minute)
       spy = self.AddEquity("SPY", Resolution.Minute)

       # Sets the fee model to the IB fee model, which simulates
       # the fees we would encounter in live trading.
       spy.FeeModel = InteractiveBrokersFeeModel()

       # Sets the fee model to a constant fee model
       aapl.FeeModel = ConstantFeeModel(0.01, "USD")
```

You can read more about Securities and their attributes at the Securities and Portfolio and Reality Modeling documentation pages.

Manual Asset Lookup

On QuantConnect, we provide the `Symbol` class to reference a security across time with a changing ticker. This is similar to Quantopian's `symbol()` function, which enables the same functionality.

When you add data to your algorithm, a `Security` object is returned. The `Symbol` is accessible from the `Security` as shown below.

```
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2000, 1, 1)
        self.SetEndDate(2020, 1, 1)
        # TWX will change to AOL when backtesting in the early 2000s, and will
        # change to TWX as the backtest advances past the date it was renamed.
        twx_security = self.AddEquity("TWX", Resolution.Minute)
        twx_symbol = twx_security.Symbol
```

To manually create a reference to an old equity, you can use the `Symbol.Create()` method, or the `Symbol.CreateEquity()` method.

You can read more about Symbols and Security Identifiers (SID) at the Security Identifiers documentation page.

Zipline

Using Data

Pipeline in Algorithms

As covered in the Initialization section, Pipelines can be replicated using Universe Selection in QuantConnect, albeit with some additional steps in between and a performance impact.

In this section, we will construct and define an equivalent pipeline model using universe selection in QuantConnect. We will filter our data set in Coarse and Fine, and apply an additional filter to historical data with a rolling window.

We first create a skeleton algorithm definition to begin setting up our Pipeline. Note that this algorithm will allow all equities through, which will have a substantial performance impact on our algorithm.

```py
class MyPipelineAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2020, 1, 1)
        self.SetEndDate(2020, 10, 20)

        self.AddUniverse(self.CoarseSelectionFunction, self.FineSelectionFunction)

    def CoarseSelectionFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        # Allows all Symbols through, no filtering applied
        return [coarse_data.Symbol for coarse_data in coarse]

    def FineSelectionFunction(self, fine: List[FineFundamental]) -> List[Symbol]:
        # Allows all Symbols through, no filtering applied
        return [fine_data.Symbol for fine_data in fine]
```

The skeleton algorithm is the equivalent of the Pipeline call below.

```py
from quantopian.pipeline import Pipeline
from quantopian.pipeline.domain import US_EQUITIES
from quantopian.research import run_pipeline

pipe = Pipeline(columns={}, domain=US_EQUITIES)
run_pipeline(pipe, '2020-01-01', '2020-10-20')
```

The equivalent of `Pipeline(screen=...)` resolves to the filter applied at the Coarse and Fine stages of universe selection. Let's define a filter of stocks with a dollar volume greater than $50000000 USD, as well as a rolling thirty day return greater than 2%. Once we've initially filtered the Symbols in Coarse Universe Selection, let's define a final filter only allowing stocks with EPS greater than 0. Beware of making `History()` calls with many Symbols. It could potentially cause your algorithm to run out of system resources (i.e. RAM) and reduce performance of your algorithm on universe selection.

```py
from datetime import datetime, timedelta

class MyPipelineAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2020, 1, 1)
        self.SetEndDate(2020, 10, 20)

        self.AddUniverse(self.CoarseSelectionFunction, self.FineSelectionFunction)

    def CoarseSelectionFunction(self, coarse: List[CoarseFundamental]) -> List[Symbol]:
        # Allows all Symbols through, no filtering applied
        dollar_volume_filter_symbols = [coarse_data.Symbol for coarse_data in coarse if
coarse_data.DollarVolume > 50000000]

        # Make a history call to calculate the 30 day rolling returns
        df = self.History(dollar_volume_filter_symbols, self.Time - timedelta(days=60), self.Time,
Resolution.Daily)

        # Compute the rolling 30 day returns
        df = df['close'].groupby(level=0).filter(lambda x: len(x) >= 30).groupby(level=0).apply(lambda x:
(x.iloc[-1] - x.iloc[-30]) / x.iloc[-30])

        # Finally, apply our filter
        dataframe_screen = df[df > 0.02]

        # Filters out any Symbol that is not in the DataFrame
        return [s for s in dollar_volume_filter_symbols if str(s) in dataframe_screen]

    def FineSelectionFunction(self, fine: List[FineFundamental]) -> List[Symbol]:
        # We receive the filtered symbols from before, and we filter by EPS > 0 in this step
       return [s.Symbol for s in fine if s.EarningReports.BasicEPS.ThreeMonths > 0]
```

This class definition is now roughly equivalent to the following `CustomFactor` and Pipeline call in Quantopian, excluding the EPS filtering.

```py
from quantopian.pipeline.filters import QTradableStocksUS
from quantopian.pipeline.factors import AverageDollarVolume

class PercentageChange(CustomFactor):
    def compute(self, today, assets, out, values):
        out[:] = (values[-1] - values[0]) / values[0]

    dollar_volume = AverageDollarVolume(window_length=5)
    dollar_volume_filter = (dollar_volume > 50000000)

    pipe = Pipeline(
        columns={
            "percent_change": PercentageChange(inputs=[USEquityPricing.close], window_length=30)
        },
        screen=(QTradableStocksUS() & dollar_volume_filter)
    )
```

An example of the shape of the DataFrame returned from History is shown below. The DataFrame has a MultiIndex, with `level=0` being the Symbol, and `level=1` being the Time for that point of data. You can index the Symbol/ `level=0` index by using either the SecurityIdentifier string (e.g. `df.loc["AAPL R735QTJ8XC9X"]`) or with the ticker of the Symbol (e.g. `df.loc["AAPL"]`)

```
                           close    high     low    open      volume
symbol time
IBM    2019-04-26 00:00:00  138.62  139.82  137.70  139.82   1419038.0
       2019-04-27 00:00:00  139.44  139.89  138.81  139.28   1275702.0
AAPL   2019-04-26 00:00:00  205.24  207.76  205.12  206.84  10105760.0
       2019-04-27 00:00:00  204.29  205.00  202.12  204.83   9984854.0
```

BarData Lookup

Similar but different, the Quantopian `BarData` object, and the QuantConnect `Slice` object both provide data to the user's algorithm as point-in-time data.

In Quantopian, data is handled via the `handle_data(context, data)` function. In QuantConnect, data is handled via the `OnData(self, slice)` method. Both of these functions accept data whenever new data exists for a given point in time. Although these two functions share the same method signature, the handling of the data is different.

`BarData` vs. `Slice`

`BarData` is the primary mechanism to retrieve the point-in-time data, as well as requesting history for any given securities in Quantopian. The following code retrieves daily historical data from 30 days into the past, as well as getting the most recent data for AAPL at the current point-in-time.

Quantopian

```
def initialize(context):
    context.aapl = sid(24)

def handle_data(context, data):
    # Gets a DataFrame of AAPL history going back 30 days
    aapl_history = data.history(context.aapl, fields=["open", "high", "low", "close", "volume"], 30, "1d")
    # Gets a pandas Series of the most recent AAPL data
    aapl_current = data.current(context.aapl, fields=["open", "high", "low", "close", "volume"])
```

QuantConnect

```
from datetime import timedelta

class MyHistoryAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.aapl = self.AddEquity("AAPL", Resolution.Daily)

    def OnData(self, slice: Slice) -> None:
        # Gets a DataFrame of AAPL history going back 30 days
        aapl_history = self.History([self.aapl.Symbol], timedelta(days=30), Resolution.Daily)

        # Gets the most recent AAPL Trade data (OHLCV)
        aapl_current = slice.Bars[self.aapl.Symbol]
```

`Slice` represents a single point in time, and does not provide the functionality to access historical data itself. To access historical data in an algorithm, use the algorithm's `self.History()` call to request a pandas DataFrame of historical data. In `Slice` , the data that is accessed is not a pandas DataFrame, but rather a single object containing data for a single point in time.

The `TradeBar` class, for example, only contains scalar values of OHLCV, rather than return a DataFrame of OHLCV values. Since the data `Slice` contains is point-in-time, there will be only a single trade/quote bar per Symbol whenever `OnData(self, data)` is called.

QuantConnect provides Quote (NBBO) data for use in your algorithm, otherwise known as a `QuoteBar` . Quote data is only accessible when an algorithm is set to consume Tick, Second, or Minutely data.

You can access Trade (OHLCV) data by accessing the `Bars` attribute of `Slice` . You can access Quote (Bid(OHLCV), Ask(OHLCV)) data by accessing the `QuoteBars` attribute of `Slice` .

Both of the `Bars` and `QuoteBars` attributes are similar to Python dictionaries, and can be used as such. To check to see if there exists a new piece of data for a given security, you can use Python's `in` operator on `Bars` and or `QuoteBars` . You can also choose to iterate on all data received by calling the `Values` attribute of the `Bars` or `QuoteBars` attributes, which will return either a list of `TradeBar` or `QuoteBar` objects.

The `TradeBar` object contains the `Open` , `High` , `Low` , `Close` , `Volume` , `Time` , `EndTime` , and `Symbol` attributes. The `QuoteBar` object contains the following attributes:

- `Bid.Open` , `Bid.High` , `Bid.Low` , `Bid.Close` , `LastBidSize`
- `Ask.Open` , `Ask.High` , `Ask.Low` , `Ask.Close` , `LastAskSize`
- `Time` , `EndTime` , and `Symbol` .

Note that the `Bid` and `Ask` attributes can potentially be `None` if no bid/ask data exists at a given point-in-time.

The example below shows the different ways to access `TradeBar` and `QuoteBar` data, as well as requesting 30 days of AAPL historical data.

PY

```
from datetime import datetime, timedelta

class MyDataAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.aapl_security = self.AddEquity("AAPL", Resolution.Daily)
        self.aapl_symbol = self.aapl_security.Symbol

    def OnData(self, slice: Slice) -> None:
        # Gets 30 days of AAPL history
        aapl_history = self.History([self.aapl_symbol], timedelta(days=30), Resolution.Daily)

        # We must first check to make sure we have AAPL data, since this point-in-time
        # might not have had any trades for AAPL (this is in case you trade a low
        # liquidity asset. The data can potentially be missing for a point-in-time).
        if self.aapl_symbol in slice.Bars:
            aapl_current_trade = slice.Bars[self.aapl_symbol]
            Log(f"{self.Time} :: TRADE :: {self.aapl_symbol} - O: {aapl_current_trade.Open} H:
{aapl_current_trade.High} L: {aapl_current_trade.Low} C: {aapl_current_trade.Close} V:
{aapl_current_trade.Volume}")

        # Check to make sure we have AAPL data first, since there might not have
        # been any quote updates since the previous for AAPL (this is in case you trade
        # a low liquidity asset. The data can potentially be missing for a point-in-time).
        if self.aapl_symbol in data.QuoteBars:
            aapl_current_quote = slice.QuoteBars[self.aapl_symbol]
            if aapl_current_quote.Bid is not None:
                Log(f"{} :: QUOTE :: {} - Bid O: {} Bid H: {} Bid L: {} Bid C: {} Bid size: {}".format(
                    str(self.Time),
                    str(self.aapl_symbol)
                    str(aapl_current_quote.Bid.Open),
                    str(aapl_current_quote.Bid.High),
                    str(aapl_current_quote.Bid.Low),
                    str(aapl_current_quote.Bid.Close),
                    str(aapl_current_quote.LastBidSize)
                ))

            if aapl_current_quote.Ask is not None:
                Log(f"{} :: QUOTE :: {} - Ask O: {} Ask H: {} Ask L: {} Ask C: {} Ask size: {}".format(
                    str(self.Time),
                    str(self.aapl_symbol),
                    str(aapl_current_quote.Ask.Open),
                    str(aapl_current_quote.Ask.High),
                    str(aapl_current_quote.Ask.Low),
                    str(aapl_current_quote.Ask.Close),
                    str(aapl_current_quote.LastAskSize)
                ))
```

Zipline

Ordering

Placing Orders

Both Quantopian and QuantConnect offer several methods for placing orders. Both platforms have `MarketOrder` , `LimitOrder` , `StopOrder` , and `StopLimitOrder` classes to create specific order types, although the `StopOrder` order is named `StopMarketOrder` on our platform. On Quantopian, creating these orders is done by passing a `style` argument to the `order` method.

```py
from zipline.finance.execution import (
    LimitOrder,
    MarketOrder,
    StopLimitOrder,
    StopOrder,
)

def initialize(context):
    context.stock = sid(8554)
    context.ordered = False

def handle_data(context, data):
    if not context.ordered:
        close = data.current(context.stock, 'close')
        order(context.stock, 10, style=MarketOrder())
        order(context.stock, 10, style=LimitOrder(limit_price=close * 0.9))
        order(context.stock, -10, style=StopOrder(stop_price=close * 0.85))
        order(context.stock, -10, style=StopLimitOrder(limit_price=close * 0.75, stop_price=close * 0.85))
        context.ordered = True
```

On QuantConnect, the same orders can be created with

```py
class MyAlgorithm(QCAlgorithm):

    def Initialize(self) -> None:
        self.SetStartDate(2020, 3, 1)
        self.SetCash(100000)
        self.symbol = self.AddEquity("SPY", Resolution.Minute).Symbol
        self.ordered = False

    def OnData(self, slice: Slice) -> None:
        if not self.ordered and slice.ContainsKey(self.symbol):
            close = slice[self.symbol].Close
            self.MarketOrder(self.symbol, 10)
            self.LimitOrder(self.symbol, 10, close * 0.9)
            self.StopMarketOrder(self.symbol, -10, close * 0.85)
            self.StopLimitOrder(self.symbol, -10, close * 0.85, close * 0.75)
            self.ordered = True
```

In addition to the order types above, QuantConnect has several other order types available. Refer to our Trading and Orders documentation for a comprehensive list.

Quantopian's `order_optimal_portfolio` method computes the optimal portfolio weights using an objective and constraints, then places the orders to achieve the desired portfolio. For example, the code below uses the Quantopian

API to create an equal-weighted dollar-neutral portfolio.

```
import quantopian.algorithm as algo
import quantopian.optimize as opt

objective = opt.TargetWeights(weights)
constraints = [
    opt.MaxGrossExposure(1.0),
    opt.DollarNeutral()
]
algo.order_optimal_portfolio(objective, constraints)
```

To acheive the same functionality with QuantConnect, we utilize portfolio construction models . For instance, to create an equal-weighted dollar-neutral portfolio, we could define the following portfolio construction model and attach it to the algorithm.

```
class MyAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.SetStartDate(2020, 5, 1)
        self.SetCash(100000)

        self.SetPortfolioConstruction(EqualWeightedDollarNeutralPortfolioConstructionModel())

class EqualWeightedDollarNeutralPortfolioConstructionModel(PortfolioConstructionModel):

    def DetermineTargetPercent(self, activeInsights: List[Insight]) -> Dict[Insight, float]:
        result = {}

        longs = 0
        shorts = 0
        for insight in activeInsights:
            if insight.Direction == InsightDirection.Up:
                longs += 1
            elif insight.Direction == InsightDirection.Down:
                shorts += 1
            result[insight] = 0

        if longs == 0 or shorts == 0:
            return result

        for insight in activeInsights:
            if insight.Direction == InsightDirection.Up:
                result[insight] = 0.5 / longs
            elif insight.Direction == InsightDirection.Down:
                result[insight] = -0.5 / shorts
        return result
```

When algorithms require manual control of their orders, both Quantopian and QuantConnect have lower-level ordering methods. Quantopian's `order` method, which places an order for a fixed number of shares, directly maps to our `Order` method. Additionally, Quantopian's `order_target_percent` method places an order to adjust a position to a target percent of the current portfolio value. Here's an example use case of these methods on the Quantopian platform.

```
order_target_percent(sid(8554), 10) # Allocate 10% of portfolio
order(sid(8554), 10) # Order 10 shares
```

On QuantConnect, these same orders can be placed using the `SetHoldings` and `Order` methods.

```
self.SetHoldings(symbol, 0.1) # Allocate 10% of portfolio
self.Order(symbol, 10) # Order 10 shares
```

Quantopian and QuantConnect don't have equivalents for all the ordering techniques, although we can create a workaround for most situations. For instance, Quantopian's `order_percent` method places an order in the specified asset corresponding to the given percent of the current portfolio value.

```
order_percent(sid(8554), 10) # Allocate 10% more of portfolio
```

To accomplish this on QuantConnect, we can determine the weight of the asset in the `Portfolio` , then manually determine the new target percent to pass to `SetHoldings` .

```
current_weight = self.Portfolio[symbol].HoldingsValue / self.Portfolio.TotalPortfolioValue
self.SetHoldings(symbol, current_weight + 0.1) # Allocate 10% more of portfolio
```

The Porfolio Object

Quantopian's `Portfolio` class provides read-only access to the current portfolio state. The state includes starting cash, current cash, portfolio value, and positions. The `Portfolio` object is accessed through the `context` object, as seen below.

```
context.portfolio.starting_cash     # Amount of cash in the portfolio at the start of the backtest
                 .cash              # Amount of cash currently held in portfolio
                 .portfolio_value   # Current liquidation value of the portfolio's holdings
                 .positions         # Dict-like object for currently-held positions
```

All of this information, and more, is attainable on QuantConnect by using our `Portfolio` object. Listed below is an example of doing so. Although there isn't a property for starting cash, this value can be saved during Initialization to be referenced later.

```
self.Portfolio.Cash                 # Sum of all currencies in account (only settled cash)
              .TotalPortfolioValue  # Portfolio equity
              .Keys                 # Collection of Symbol objects in the portfolio
              .Values               # Collection of SecurityHolding objects in the portfolio
```

On Quantopian, by iterating through the `positions` dictionary, we can access information about currently-held positions. This includes the number of shares held, the last traded price & date of the asset, and the position's cost basis.

```
for sid, position in context.portfolio.positions.iteritems():
    position.amount            # Number of shares in the position
            .cost_basis        # Volume weighted average price paid per share
            .last_sale_price   # Price at last sale of the asset on the exchange
            .last_sale_date    # Date of last sale of the asset on the exchange
```

Since the `Portfolio` on QuantConnect is a `Dictionary<Symbol, SecurityHolding>` , we can get information on current positions by indexing the `Portfolio` object with a `Symbol` or ticker. The `SecurityHolding` object that is returned contains information related to a single security in the portfolio. For instance, we have

```
self.Portfolio[symbol].Quantity                # Number of shares held
                       .AveragePrice           # Average price of shares held (aka cost basis)
                       .Price                  # Last traded price of the security
```

For more information on our `Portfolio` object refer to the Securities and Portfolio documentation.

Zipline

Logging and Plotting

Logging

In QuantConnect, the `self.Debug()` method is the equivalent of the `log.info()` function in Quantopian. Debug output is viewable via the QuantConnect Terminal Console.

Output to the console via `self.Debug()` is rate-limited. If you need long-term storage of your logs and don't want to overflow the console, consider using `self.Log()` instead. An example comparing logging between Quantopian and QuantConnect is shown below.

Quantopian

```py
def initialize(context):
    log.info("Hello, console!")
```

QuantConnect

```py
class MyLoggingAlgorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.Debug("Hello, console!")
        self.Log("Hello, backtesting logs!")
```

Logging via `self.Log()` has daily limits in QuantConnect. On the free tier, users are limited to 10KB of logs per day for your account/organization. To increase this limit, you can upgrade your account to a different tier. Calls to `self.Debug()` will also count towards the 10KB log limit, but are always outputted to the Terminal Console regardless of your daily log limit.

To view pricing and upgrade your account, visit the Organization Pricing page.

You can view the logs generated via `self.Log()` for a backtest by first accessing a backtest, and clicking the "Logs" tab near the bottom of the page. To download the logs, you can click the "Download Logs" link to download a text file containing your backtest's logs.

Plotting

In Quantopian, plotting/charting is done with the `record(series1_name=scalar_value, series2_name=scalar_value, ...)` function. In QuantConnect, plotting is accessible via the `self.Plot("chart name", "series name", scalar_value)` method.

Plotting multiple series in one function call is possible in Quantopian. However, in QuantConnect, a separate call is needed for each series requiring an update. All series with the same chart name will appear on the same window/pane. New charts can be created by calling `self.Plot()` method with a unique chart name.

An example of plotting in Quantopian vs. QuantConnect is shown below. The QuantConnect code will create two charts, one named "Chart1" with two series of data, and another named "Chart2" with one series of data. Note that you can also use `self.Plot("series name", value)` to place the custom series on the same chart as the equity curve.

Quantopian

```py
import numpy as np
from quantopian.algorithm import record

    def initialize(context):
        context.i = 0

    def handle_data(context, data):
        context.i += 0.25

        record(
            Series1=np.sin(context.i),
            Series2=np.cos(context.i),
            Series3=np.tan(context.i)
        )
```

QuantConnect

```py
import numpy as np

class Algorithm(QCAlgorithm):
    def Initialize(self) -> None:
        self.i = 0

    def OnData(self, slice: Slice) -> None:
        self.i += 0.25

        self.Plot('Chart1', 'Series1', np.sin(self.i))
        self.Plot('Chart1', 'Series2', np.cos(self.i))
        self.Plot('Chart2', 'Chart2 Series1', np.tan(self.i))
```

For more information on plotting in QuantConnect, visit the Charting documentation page.

Zipline

Quick Reference

User-Implemented Functions

The following table describes functions that are treated specially when defined in the IDE.

Algorithms are required to implement one method: Initialize(self).

An optional scheduled event can be defined to behave like before_trading_start(). OnData() is also optional but is treated especially if defined.

Quantopian	**QuantConnect**
`initialize` (context)	`Initialize` (self)
Required function called once at the start of a backtest.	
`before_trading_start` (context, data)	`self.Schedule.On(self.DateRules.EveryDay(), self.TimeRules.AfterMarketOpen(symbol, 10), self.before_trading_start)`
Optional function called prior to market open on every trading day.	
`handle_data` (context, data)	`OnData` (self, slice)
Optional function called at the end of each market minute.	

Interface Classes

The following table describes classes that are passed to `initialize()` , `handle_data()` , `before_trading_start()` and any scheduled with `schedule_function()` .

In QuantConnect/Lean, the portfolio state and the positions are class attributes of QCAlgorithm, available via self keyword. The scheduled function is parameterless and can algorithms can self.CurrentSlice.

Quantopian	QuantConnect
`quantopian.algorithm.interface.AlgorithmContext`	`QCAlgorithm`
Shared object for storing custom state.	
`quantopian.algorithm.interface.BarData`	`Slice`
Provides methods for accessing minutely and daily price/volume data from Algorithm API functions.	
`quantopian.algorithm.interface.Portfolio`	`self.Portfolio`
Object providing read-only access to current portfolio state.	
`quantopian.algorithm.interface.Positions`	`self.Transactions`
A dict-like object containing the algorithm's current positions.	

The features from the BarData methods are found in the Slice object (current data), History method (past data) and class attribute Securities.

Quantopian	QuantConnect
`quantopian.algorithm.interface.BarData.current`	`Slice[symbol]`
Returns the "current" value of the given fields for the given assets at the current simulation time.	
`quantopian.algorithm.interface.BarData.history`	`self.History(symbols, bar_count)`
Returns a trailing window of length `bar_count` containing data for the given assets, fields, and frequency.	
`quantopian.algorithm.interface.BarData.can_trade`	`self.Securities[symbol].IsTradable`
For the given asset or iterable of assets, returns True if all of the following are true:	
`quantopian.algorithm.interface.BarData.is_stale`	`not Slice[symbol].IsFillForward`
For the given asset or iterable of assets, returns True if the asset is alive and there is no trade data for the current simulation time.	

Pipeline

The following table describes functions used to schedule and retrieve results of Universe selection. For more information on the Universe Selection API, see the Univeres API Reference.

Quantopian	QuantConnect
`quantopian.algorithm.attach_pipeline` (...)	`universe = self.AddUniverse` (...) name = universe.Configuration.Symbol
Register a pipeline to be computed at the start of each day.	
`quantopian.algorithm.pipeline_output` (name)	`self.UniverseManager` [name]
Get results of the pipeline attached by with `name` .	

Scheduling Functions

The following tables describes functions that can be used to schedule functions to run periodically during your algorithm.

Quantopian	QuantConnect
`quantopian.algorithm.schedule_function` (func)	`self.Schedule.On(IDateRule, ITimeRule, func)`
Schedule a function to be called repeatedly in the future.	

Date Rules

The following table contains functions that can be used with the `date_rule` parameter of `schedule_function()` .

Quantopian	QuantConnect
`quantopian.algorithm.date_rules.every_day` ()	`self.DateRules.EveryDay(symbol)`
Create a rule that triggers every day.	
`quantopian.algorithm.date_rules.month_start` ([...])	`self.DateRules.MonthStart(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days after the start of each month.	
`quantopian.algorithm.date_rules.month_end` ([...])	`self.DateRules.MonthEnd(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days before the end of each month.	
`quantopian.algorithm.date_rules.week_start` ([...])	`self.DateRules.WeekStart(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days after the start of each week.	
`quantopian.algorithm.date_rules.week_end` ([...])	`self.DateRules.WeekEnd(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days before the end of each week.	

Time Rules

The following table contains functions that can be used with the `time_rule` parameter of `schedule_function()` .

Quantopian	QuantConnect
`quantopian.algorithm.time_rules.market_open` ([...])	`self.TimeRules.AfterMarketOpen(symbol, minutes_after_open = 0)`
Create a rule that triggers at a fixed offset from market open.	
`quantopian.algorithm.time_rules.market_close` ([...])	`self.TimeRules.BeforeMarketClose(symbol, minutes_before_close = 0)`
Create a rule that triggers at a fixed offset from market close.	

Ordering

There are several ways to place orders from an algorithm. For most use-cases, we recommend using SetHoldings method which correctly accounts the porfolio buying power model and fees. At the moment, there is no equivalent for `order_optimal_portfolio()` . However a similar behavior can be replicated with a Portfolio Construction Model.

Algorithms that require explicit manual control of their orders can use the lower-level ordering functions.

Placing Orders

Quantopian	QuantConnect
`quantopian.algorithm.order_optimal_portfolio` (...)	`N/A`
Calculate an optimal portfolio and place orders toward that portfolio.	
`quantopian.algorithm.order` (asset, amount[, ...])	`self.Order(symbol, amount)`
Place an order for a fixed number of shares.	
`quantopian.algorithm.order_value` (asset, value)	`N/A`
Place an order for a fixed amount of money.	
`quantopian.algorithm.order_percent` (asset, ...)	`self.SetHoldings(symbol, percent)`
Place an order in the specified asset corresponding to the given percent of the current portfolio value.	
`quantopian.algorithm.order_target` (asset, target)	`N/A`
Place an order to adjust a position to a target number of shares.	
`quantopian.algorithm.order_target_value` (...)	`N/A`
Place an order to adjust a position to a target value.	
`quantopian.algorithm.order_target_percent` (...)	`self.SetHoldings(symbol, percent)`
Place an order to adjust a position to a target percent of the current portfolio value.	

Controlling Order Execution

Quantopian	QuantConnect
`zipline.finance.execution.ExecutionStyle`	`FillModel`
Base class for order execution styles.	
`zipline.finance.execution.MarketOrder` ([exchange])	`self.MarketOrder` (symbol, quantity)
Execution style for orders to be filled at current market price.	
`zipline.finance.execution.LimitOrder` (limit_price)	`self.LimitOrder` (symbol, quantity, limit_price)
Execution style for orders to be filled at a price equal to or better than a specified limit price.	
`zipline.finance.execution.StopOrder` (stop_price)	`self.StopMarketOrder` (symbol, quantity, stop_price)
Execution style representing a market order to be placed if market price reaches a threshold.	
`zipline.finance.execution.StopLimitOrder` (...)	`self.StopLimitOrder` (symbol, quantity, stop_price, limit_price)
Execution style representing a limit order to be placed if market price reaches a threshold.	

Managing Existing Orders

Quantopian	QuantConnect
`quantopian.algorithm.get_order` (order_id)	`self.Transactions.GetOrderById` (order_id)
Lookup an order based on the order Id returned from one of the order functions.	
`quantopian.algorithm.get_open_orders` ([asset])	`self.Transactions.GetOpenOrders` (symbol)
Retrieve all of the current open orders.	
`quantopian.algorithm.cancel_order` (order_param)	`self.Transactions.CancelOpenOrders` (symbol)
Cancel an open order.	

Customizing the Simulation

Slippage

Algorithms can customize the simulation of order fills by calling SetSlippageModel() with a ISlippageModel which is any class that implements GetSlippageApproximation method. Unlike Quantopian, the slippage model is a security attribute, not a global attribute. Different securities can have different slippage models.

The default slippage model on QuantConnect is a constant slippage model with zero slippage percent (no slippage).

Quantopian	QuantConnect
`quantopian.algorithm.set_slippage` ([...])	`self.Securities[symbol].SetSlippageModel(ISlippageModel)`
Set the slippage models for the simulation.	
`zipline.finance.slippage.SlippageModel` ()	`N/A (class must implement GetSlippageApproximation method)`
Abstract base class for slippage models.	
`zipline.finance.slippage.FixedBasisPointsSlippage` ([...])	`ConstantSlippageModel(slippage_percent)`
Model slippage as a fixed percentage difference from historical minutely close price, limiting the size of fills to a fixed percentage of historical minutely volume.	
`zipline.finance.slippage.NoSlippage` ()	`ConstantSlippageModel(0)`
A slippage model where all orders fill immediately and completely at the current close price.	
`zipline.finance.slippage.FixedSlippage` ([spread])	`N/A`
Simple model assuming a fixed-size spread for all assets.	
`zipline.finance.slippage.VolumeShareSlippage` ([...])	`N/A`
Model slippage as a quadratic function of percentage of historical volume.	

Commissions

Algorithms can customize the simulation of order fees by calling SetFeeModel() with a IFeeModel which is any class that implements GetOrderFee method. Unlike Quantopian, the fee model is a security attribute, not a global attribute. Different securities can have different fee models.

The default fee model on QuantConnect depends on the security type and the brokerage. For instance, the default fee model for equity is the Interactive Brokers fee model.

Quantopian	QuantConnect
`quantopian.algorithm.set_commission` ([...])	`self.Securities[symbol].SetFeeModel(IFeeModel)`
Sets the commission models for the simulation.	
`zipline.finance.commission.CommissionModel`	`N/A (class must implement GetOrderFee method)`
Abstract base class for commission models.	
`zipline.finance.commission.PerShare` ([cost, ...])	`N/A`
Calculates a commission for a transaction based on a per share cost with an optional minimum cost per trade.	
`zipline.finance.commission.PerTrade` ([cost])	`N/A`
Calculates a commission for a transaction based on a per trade cost.	
`zipline.finance.commission.PerDollar` ([cost])	`N/A`
Model commissions by applying a fixed cost per dollar transacted.	
`zipline.finance.commission.NoCommission`	`FeeModel()`
Model commissions as free.	

Benchmark

The default benchmark is SPY.

Quantopian	QuantConnect
`quantopian.algorithm.set_benchmark` (benchmark)	`self.SetBenchmark` (benchmark)
Set the benchmark asset.
